FIG. 3.—EUGLENA AGILIS, A GREEN FLAGELLATE. MAGNIFIED ABOUT 1,500 TIMES

sometimes in relation to the protrusion of cilia or flagella. Also in the ectoplasm there may be skeletogenous material in the form of rods, plates and fibrils, and contractile fibres or myonemes, as well as specialized organelles serving other functions, particularly those which are in direct relation to the environment of the cell.

The endoplasm, in contrast with the ectoplasm, is relatively fluid, markedly granular and vacuolated; the last character giving the impetus to O. Buetschli's well-known "alveolar theory" (1878, 1892) of the finer structure of protoplasm. Within the endoplasm is the nuclear apparatus, comprising one or more nuclei, and most of the organelles, such as gastric vacuoles, contractile vacuoles and chromatophores, as well as stored proteins, carbohydrates and fats, and crystals and other metaplasmic bodies. Chondriosomes and Golgi bodies have been described in many species and probably are always present.

Motor Organelles.—Motor organelles—pseudopodia, flagella and cilia—have served from the time of Felix Dujardin (1841) to demark three of the great groups of Protozoa. Pseudopodia are temporary extensions of the body which range in complexity from mere outflowings of the protoplasm of the cell, as seen in *Amoeba proteus* and its allies, to more definitely formed structures as found in the Heliozoa and many Radiolaria. All pseudopodia function to some extent in locomotion and prehension of food, but the latter use predominates in many species. Four general types of pseudopodia may be distinguished, each of which is characteristic of certain species, though subject to considerable modification under varying surroundings. Lobopodia are relatively broad and usually blunt outflowings of both ectoplasm and endoplasm (*e.g.*, in common Amoebae); filopodia are long, slender, pointed threads of ectoplasm (*e.g.*, in *Euglypha*); myxopodia are threadlike and tend to branch and fuse to form large meshworks (*e.g.*, in the Foraminifera); and axopodia are relatively stiff raylike processes, each consisting of an axial filament arising from a basal body in the cell and enclosed by a layer of flowing protoplasm (*e.g.*, in the Heliozoa). Axopodia in certain species approach the structure of flagella and have been regarded as evidence of a close relationship between the Heliozoa and Mastigophora. (Figs. 2, 6.)

Flagella are long, vibratile threads of protoplasm which extend from the surface of the cell and function chiefly as locomotor organs, but also may serve to waft food-bearing currents toward the animal or to explore the immediate surroundings in a sensory capacity. The number of flagella varies in different species from one to hundreds, but usually does not exceed four. Typically they arise at the anterior end of the cell and project forward, but in many common species with two flagella (*e.g.*, *Bodo* sp.) one flagellum trails posteriorly, acting as a gliding organ or rudder. There may be considerable variations in length and also in form of the flagella in the same and different species. Most flagella are circular in cross section, but some are flattened or form the edge of an undulating membrane as in certain parasitic flagellates (*e.g.*, Trypanosomes). The finer structure of flagella is extremely difficult to determine, but from the study of favourable examples it evidently consists of two parts—an elastic sheath which envelopes an axial vibratile filament, the latter being an outgrowth of a basal body, or blepharoplast. The mechanism of flagellar movement is apparently inherent in the flagellum itself because it retains activity when isolated with its basal body. The basal body is a centriole, or a derivative of a centriole, which is usually situated just under the cell surface near the point of exit of the axial filament but may lie deeper and be closely associated with the nucleus. In many species the kinetic system is complicated by multiple basal bodies, parabasal bodies, axostyles, rhizoplasts and other elements of unknown function too diverse to be briefly summarized. (Figs. 3, 16, 19.)

Cilia are relatively short protoplasmic threads which arise from basal bodies in the ectoplasm of all species of the Ciliophora. They are usually exceedingly numerous and form longitudinal rows that may be evenly distributed over the surface of the cell or restricted to certain regions and differentiated for special functions. Thus the union of the cilia in a row or the union of rows of cilia, or both, form such complexes as undulating membranes and membranelles in the oral region for wafting food into the peristome, while the fusion of tufts of cilia constitutes bristlelike cirri for crawling and tactile purposes. The basic structure and mechanism of movement of cilia appear to be similar to that of flagella, but the effectiveness of ciliary action is caused by waves of contraction passing along the rows, each composed of a multitude of cilia coordinated by underlying fibres that connect the basal bodies. (Figs. 1, 14.)

Nucleus.—The nuclei of the Protozoa have the same basic structure and function as in metazoan cells: a nuclear membrane encloses the karyolymph in which are embedded achromatic and chromatic elements; the latter constitutes the definitive chromosomes. However, the nuclei show much more variation in general structure than do those of the Metazoa, and in many cases kinetic bodies are intranuclear. All attempts to arrange a satisfactory evolutionary series of nuclear types have failed, largely because diverse types may occur in obviously closely related species. It is customary to classify protozoan nuclei in a broad way as either vesicular or massive. In the former type

FIG. 4.—GENERAL SCHEME OF THE LIFE HISTORY OF A HUMAN MALARIAL PARASITE, PLASMODIUM

the chromatin is concentrated in a centrally located body, the endosome, surrounded by a zone of clear karyolymph; but there are many gradations between this condition and the massive type in which the chromatin is distributed evenly throughout so that the nucleus presents a comparatively homogeneous appearance. Both nuclear types may be found in the same genus: the micronuclei are typically vesicular in some species of *Paramecium* and approach the massive in others.

The majority of Protozoa contain a single nucleus, but there are many species with two or more nuclei, and some with hundreds. Common forms with many nuclei are represented by the large freshwater rhizopod, *Pelomyxa,* certain stages of the Mycetozoa and some of the parasitic ciliates of the frog, such as *Opalina.* Multiple nuclei may be present during nearly the whole life of a species, or only in stages preparatory to reproduction by multiple division.

A unique and characteristic condition prevails in nearly all of the ciliates, where the typical nuclear apparatus comprises two structurally differentiated parts: usually one relatively large macronucleus and one or more micronuclei. Both types divide during cell division, but the macronucleus is apparently a composite nucleus which as a whole divides amitotically in distributing its component elements which may individually divide mitotically. The micronuclei divide by typical mitosis and on them depends the origin of gametic nuclei, and the formation of a new macronucleus after fertilization as well as in a nuclear reorganization process known as endomixis (fig. 1).

In addition to the formed nuclei, sometimes there are granules distributed in the cytoplasm that have been released from the nucleus. Many of these take nuclear stains and are undoubtedly chromatin, but the chromatin nature of others is highly questionable. The chromatin granules, or chromidia, gave rise to elaborate theories, by R. Hertwig and his school, in regard to their cell function, particularly in reference to the nucleo-cytoplasmic relationship and to the origin of the nuclei of gametes. It is generally accepted that a delicately balanced proportionality normally exists between the volume of nucleus and cytoplasm of a cell, a relationship which, however, varies within limits during different phases of cellular activity. Granting this, it is assumed that the nucleo-cytoplasmic ratio is under certain conditions maintained by the elimination of chromatin from the nucleus. This may well be true, though crucial evidence that chromidia function in this way is lacking. But the aspect of the "chromidial hypothesis" which is of most interest assumes that formed nuclei, especially of the gametes, arise from chromidia in certain species. A number of categorical descriptions of such an origin have been given, but more recent observations demonstrate beyond peradventure in all cases that have been critically re-examined (*e.g.,* in the Foraminifera) that the nuclei of the gametes are formed by a continuous series of mitotic divisions involving definite chromosome distribution.

It is clear then that nuclear division, long believed to be amitotic in many Protozoa, is really mitotic since it involves the exact distribution of chromosomes or elements comparable with chromosomes in metazoan cells. This has been demonstrated by observations on dividing nuclei in certain species, and also by the results derived from genetic studies that can be interpreted only from the standpoint of a segregating mechanism as in Metazoa. It is true that the macronucleus of ciliates divides as a whole amitotically but, significantly, is replaced periodically from mitotically dividing micronuclei. Although in many species of Protozoa definitive chromosomes have not actually been seen, in others specific chromosomes have been unequivocally identified in both the haploid and diploid state; *e.g.,* the diploid number in the sporozoan, *Aggregata eberthi,* is 12, and in the foraminifer, *Patellina corrugata,* is 24. In most cases the chromosome number is within the usual range of that found in metazoan cells, say less than 50, although polyploidy may greatly increase the number, as in certain races of *Paramecium bursaria.* Again the number may mount to more than a thousand, as in the so-called polyenergid nuclei of some of the Radiolaria that may be essentially aggregates of nuclei.

In contrast with metazoan nuclei, the protozoan nuclear membrane usually persists during mitosis, and the centrioles or comparable kinetic agents, as well as the spindle, are intranuclear. However, variations are very numerous and range from cases where part of the mitotic apparatus is outside the membrane to those in which the whole mitotic figure arises in the adjacent cytoplasm (figs. 8, 9).

FIG. 6.—A HELIOZOAN, ACTINOPHRYS SOL. MAGNIFIED ABOUT 400 TIMES

Nutrition.—Various methods of nutrition occur in the Protozoa and, in general, these are characteristic of particular groups. Autotrophic, or holophytic, nutrition is found in the chlorophyll-bearing species, particularly in the phytoflagellates, and involves photosynthesis as in green plants, but some of these species, even in the light, require nitrogen in organic combinations, such as amino acids. In the absence of light most autotrophic forms (*e.g., Euglena*) can absorb organic substances dissolved in the medium and so live by the saprozoic method, whereas many of the free-living flagellates without chlorophyll and nearly all parasitic Protozoa are solely saprozoic. But variations in details of nutrition are legion. For example, it appears that some of the free-living, colourless flagellates can be cultivated on a remarkably simple inorganic medium to which acetate has been added as a carbon source. Indeed, it is becoming increasingly clear from extensive studies on pure cultures of various species and races of flagellates, rhizopods and ciliates in controlled media, where the significance of vitamins, trace elements, and so on may be determined, that there are many intermediate gradations between typical autotrophic and saprozoic nutrition and between the latter and holozoic nutrition in which particulate food is required. To define this nutritional versatility a highly elaborate but unsettled terminology has been developed.

The majority of the free-living species are holozoic, ingesting solid food, usually micro-organisms, such as bacteria and yeasts, and other Protozoa. This involves the development of a wide variety of methods for securing and ingesting the food. In most rhizopods the mere contact of the nutrient material with nearly any point on the exposed surface of the protoplasm is followed by its gradual engulfment by pseudopodial action; in other species a special receptive point for ingestion is provided. This may consist, as in some flagellates, merely of an exposed region at the anterior end near the base of the flagellum, or, as in many ciliates, of a definite cytostome leading into the endoplasm. The cytostome may be terminal but more often in the ciliates it is situated laterally and ventrally in a funnel-like depression of the surface, the peristome, and opens into a tubular gullet extending into the endoplasm. Ciliary action in the peristome wafts the food particles in a vortex toward the mouth and accordingly it is in this region that special groups of cilia, such as undulating membranes and membranelles, are present. Species so provided feed continually if food is available because the mouth is permanently open. It has been conservatively estimated that a *Paramecium* may ingest as many as 5,000,000 bacteria in 24 hours. In various other species the mouth is open only when occasion demands. This is particularly true in the case of carnivorous forms which capture prey when chance brings it within reach, as is well illustrated by ciliates such as *Didinium,* whose sole diet consists of *Paramecium,* and *Spathidium,* which feeds on *Colpidium* and closely similar small ciliates. In such cases the food is "selected" by limitations imposed by the character

of the oral apparatus. Thus the seizing organ of *Didinium* is in some way adapted so that it adheres to the pellicle of *Paramecium* and not to that of other organisms with which it happens to come in contact. Quite a different method of food capture is employed by the free-living Suctoria, which in the adult state are devoid of cilia but are provided with tentacles. Prey, such as a small ciliate, coming in contact with the tentacles is paralyzed, presumably by some poisonous secretion, and thereupon its endoplasm is sucked out until there is merely a collapsed remnant. (Figs. 10, 11).

In some species the ingested food appears to lie directly in contact with the endoplasm, but more often it is in a droplet of water, taken in at the same time, that constitutes a gastric vacuole. In most ciliates, such as *Paramecium*, the vacuole passes from the gullet into the endoplasm, where it is carried along a more or less definite course through the cell by cyclosis. During this passage digestive enzymes, etc., are secreted into the vacuole. The reaction of the vacuolar content varies from acid to alkaline, and the presence of proteinases and amylases has been demonstrated, but in very few Protozoa is there definite evidence of the digestion of fats, although this undoubtedly occurs. However, the details of digestion are largely undetermined, not only because of the delicacy of the technique involved in the study but also because the process varies in different species and in the same species with the nature of the available food. In any event the digestible contents of the vacuole gradually disappear as it circulates through the endoplasm and then the useless residue passes out of the cell, usually at a definite point, the cytoproct. It appears that gastric vacuoles containing material of no food value are rejected after a relatively short course in the cell. (Fig. 1.)

FIG. 7.—A RADIOLARIAN, THALASSICOLLA NUCLEATA. MAGNIFIED ABOUT 15 TIMES

Respiration.—With the wide distribution of Protozoa in nearly every ecological niche of nature, it is not strange that their respiratory processes show considerable variation. The majority of species are strictly aerobic, demanding free oxygen for their normal metabolic processes. This is secured with the intake of water with food and also by diffusion through the whole surface of the body, since structurally differentiated respiratory organs are not present. Similarly the outgo of CO_2 is apparently accomplished by the cellular membrane, probably incidentally aided to some extent by the contractile vacuolar system when it is present. The oxygen uptake and the CO_2 output varies greatly in different species and in the same species under altered internal and external conditions. Experiments indicate that the hourly rate of oxygen consumption of *Paramecium calkinsi* at 20° C. is of the order of magnitude of 28 cu.mm. per 100,000 animals.

Some typically aerobic forms are able to exist for a considerable time as facultative anaerobes and obtain energy from processes that do not require free oxygen, such as the breakdown of glycogen into lactic acid. *Paramecium* can survive for about 12 hours in the absence of free oxygen. But there are many species that are largely or entirely anaerobic, in particular various endoparasitic forms and those inhabiting mud and highly polluted sewage water. Indeed, free oxygen is lethal for certain species.

Contractile Vacuole.—One of the most interesting among the organelles of the Protozoa is the contractile vacuole that occurs in the majority of fresh-water species, but is usually absent in marine and parasitic forms other than the ciliates. The vacuole appears and disappears rhythmically from view as it gradually accumulates and then expels fluid from the cell. In most forms the vacuole occupies a definite position in the cell, but in Amoebae the general location changes as the animal flows along. Commonly there is only one vacuole, but some species possess two or several. Furthermore, the definitive vacuole, especially in the ciliates, may be the focus of a vacuolar system comprising accessory canals that radiate from the vacuole (*e.g.*, in *Paramecium*) or ramify widely through the endoplasm (*e.g.*, in *Frontonia*). In most cases the vacuole is supplied by the migration of tiny droplets of fluid and accessory vacuoles which coalesce at the contractile vacuolar locus or with some part of the canal system when such is present. Many observations indicate that at least some of the droplets of fluid originate in association with osmophilic material, probably representing the so-called Golgi apparatus.

FIG. 8.—MITOSIS (METAPHASE) DURING DIVISION OF A HELIOZOAN, ACANTHOCYSTIS ACULEATA. MAGNIFIED VERY HIGHLY

Although it is difficult to determine the nature of the delimiting surface of the vacuole, it seems clear that some types are surrounded by a structural membrane in addition to the theoretically necessary physiological membrane. Again in some cases the vacuole discharges through a definitive excretory pore, while in others the pore is temporary. The rate of vacuolar contraction varies in different species and also in the same species with changes in the osmotic pressure of the surrounding medium, temperature, and other factors, but in general the vacuolar cycle ranges in duration from a few seconds to a minute.

FIG. 9.—NUCLEUS OF A CILIATE, ZELLERIELLA INTERMEDIA, IN MITOTIC DIVISION (ANAPHASE) SHOWING TWO DAUGHTER SETS OF 24 CHROMOSOMES. MAGNIFIED ABOUT 2,000 TIMES

The first significant suggestion relative to the function of the contractile vacuolar system was made in 1776 by Lazzaro Spallanzani, who regarded it as respiratory, but it is now believed, as first emphasized by M. Hartog in 1888, to be chiefly associated with the maintenance of the proper osmotic relations between the cell and its surroundings by regulating the water content of the protoplasm. A *Paramecium* with two contractile vacuoles may eliminate its own body volume of water in less than 20 minutes. That this system also acts in an excretory capacity to eliminate CO_2 and nitrogenous wastes has not been satisfactorily determined, though undoubtedly such material must incidentally, at least, pass out in the vacuolar fluid. However, the fact that many Protozoa are without contractile vacuoles makes it clear that these organelles are not invariably necessary for such indispensable functions.

Reproduction.—Although reproduction in all animals and plants is basically dependent upon cell division, this is most evident in unicellular forms where the parent individual divides into daughter cells and so loses its individuality. The important types of cell multiplication in the Protozoa are commonly referred to as binary fission, budding and sporulation—all intrinsically asexual processes though in certain instances leading to the formation of gametes. Binary fission involves the division of the cell, both nucleus and cytoplasm, into two essentially equal daughter cells that grow into replicas of the parent. So stated the process seems simple, but obviously it involves making each

half into a whole. Dedifferentiation of various structures in the parent cell must be followed by differentiation in the daughter cells. Although some organelles are taken over intact, in general the daughter cells are essentially "new" organisms. For instance, in many of the specialized ciliates it has been possible to show that the highly modified groups of cilia, or cirri, are resorbed and new ones arise in, or migrate to, the proper relative positions on the daughter cells.

Many gradations occur between binary fission and budding, or gemmation, in which the parent cell retains its identity while producing by division one or many daughter cells. Sometimes a bud is essentially as large as the parent, so the result is nearly the same as binary fission except that parent and offspring can be distinguished; but usually the bud is much smaller, less differentiated, and gradually assumes the parent form after it has become free. This condition is well seen in the sessile Suctoria, where the buds become detached as free-swimming, ciliated embryos which finally settle down and develop tentacles and other adult characters. In some species the buds arise on the surface of the parent and in others within deeply invaginated "brood chambers" from which they escape at "birth." The former is referred to as exogenous and the latter as endogenous budding.

Multiple budding leads by various transitions to sporulation, in which the nucleus of the parent cell divides a number of times, followed by the division of the cell body into as many cells as there are nuclei, so that the parent cell becomes resolved into many progeny. Sporulation is obviously a method of very rapid multiplication and is especially characteristic of parasitic forms, such as the Sporozoa with complicated life cycles including asexual and sexual phases. Thus in many species an asexual phase, known as schizogony, is followed by the development of sex cells and zygote formation. This in turn leads to spore formation, or sporogony, and so completes the life cycle. But other variations in reproduction are legion. For instance, so-called plasmotomy sometimes occurs in multinucleate species such as some of the Opalinid ciliates; the cytoplasm divides into two parts, each retaining the nuclei that are in it at the time. A continuation of this process may produce uninucleate cells. (Fig. 4).

Colonies.—Reproduction in the vast majority of the Protozoa results in individuals that move apart and live a completely separate existence, but in certain species the cells formed by division remain associated so that colonies result. Protozoan colonies vary widely in form ranging from essentially amorphous groups of individuals, or zooids, embedded in a gelatinous substance, to those in which the zooids assume definite spatial relations with each other so as to constitute linear, platelike, spherical or arboroid colonies. All of the individuals composing a colony are, with few exceptions, structurally the same and physiologically independent, though the colony may swim by the combined action of the flagella of its component zooids (*e.g.*, *Gonium*) or contract as a whole by virtue of a common stalk (*e.g.*, certain arboroid colonies among the ciliates).

Colony formation in some of the phytoflagellates of the family Volvocidae is of special interest because there are various gradations from small groups of individuals, in structure quite similar to those of closely related noncolonial species, to complex colonies of thousands of cells. Representatives of the simpler types are the several species of *Gonium* that are square, platelike colonies of from 4 to 16 zooids, usually in a gelatinous matrix; and of *Pandorina* and *Eudorina* that consist of spherical groups of 16 or 32 zooids similarly embedded. All of the zooids have the same structure and are capable of asexual and sexual reproduction. But a differentiation of somatic and reproductive zooids appears in various species of *Pleodorina,* comprising up to 128 zooids, and *Volvox,* often consisting of many thousands of zooids connected by protoplasmic strands and forming the surface of a gelatinous sphere. So there is a demarcation of somatic and germinal regions of the colony that is prophetic of the further individualization and attendant physiological division of labour characteristic of the true multicellular organisms. In the case of *Volvox*, particularly, the fact that it is difficult to draw a hard and fast line between a colony and a metazoan individual is evident, and probably such a colony would be regarded as an individual were there not gradations between it and closely related noncolonial species. Students of phylogeny consider most acceptable the view that the Metazoa were derived from a spherical colony of flagel-

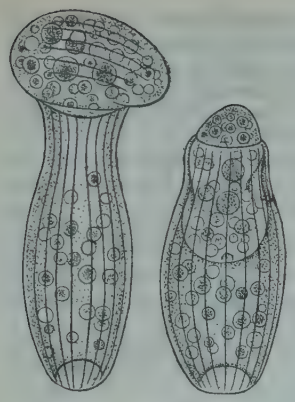
FIG. 10.—SECTION OF THE SURFACE OF A SUCTORIAN, TOKOPHRYA LEMNARUM, SHOWING TENTACLES CONTRACTED, FULLY EXTENDED AND IN THE ACT OF FEEDING. MAGNIFIED ABOUT 2,000 TIMES

lates, not greatly dissimilar to *Volvox*. This view receives support from similarities in the method of development of *Volvox* and some calcareous sponges. (Fig. 12.)

Sex.—Sexual phenomena are wide-spread in the Protozoa but evidently are not universal, as was formerly assumed, because intensive studies of many species have given no supporting evidence. Sex in the Protozoa is expressed in the same basic way as in the rest of the animal kingdom, involving intrinsically the formation of male and female sex cells, or gametes, whose nuclei unite in the zygote to form a composite nucleus, or synkaryon. In some species mature sexual individuals, which are not recognizably differentiated except by their behaviour, unite in pairs and melt together, cytoplasm with cytoplasm and nucleus with nucleus, to form a zygote. In various other species the gametes show nearly all possible gradations in differentiation, both of size and behaviour, finally resulting in minute active sperm and large passive eggs as in most Metazoa. Furthermore, in the ciliates (*e.g.*, in *Paramecium*) a unique process known as conjugation prevails, in which two similar individuals come in contact and temporarily unite about the oral region. Then in each of the conjugants two gametic nuclei of micronuclear origin are formed, one of which migrates into the other conjugant and fuses with its "stationary" nucleus to form a synkaryon. Accordingly this exchange results in mutual fertilization of the conjugating animals which thereupon separate, re-establish the typical nuclear apparatus from the synkaryon, and proceed to reproduce by binary fission. However, in some ciliates, represented by the sessile Vorticellids, mutual fertilization does not occur; the conjugants are differentiated in size and behaviour so that free-swimming microconjugants unite with and fertilize sessile macroconjugants. (Fig. 13.)

In most instances the uniting gametes are produced by distantly related cells, but sometimes the reverse is true. They may be separated merely by a cell division or two from a common parent, as in some heliozoans, *e.g.*, *Actinophrys* and *Actinosphaerium,* so that very close inbreeding, known as paedogamy, occurs; while in extreme cases the gametic nuclei arise and fuse in the



FROM WOODRUFF & SPENCER, "JOURNAL OF EXPERIMENTAL ZOOLOGY," (WISTAR INST. OF ANATOMY AND BIOLOGY)

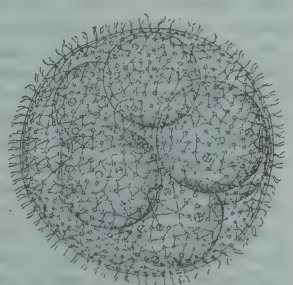
FIG. 11.—A CILIATE, SPATHIDIUM SPATHULA, CAPTURING AND SWALLOWING A COLPIDIUM. HIGHLY MAGNIFIED

same cell that produced them and so-called autogamy results. The latter takes place under certain conditions in *Paramecium* and some other ciliates, as also does endomixis in which a synkaryon is not formed although a new nuclear apparatus arises from a micronucleus. Endomixis simulates many of the nuclear phenomena of autogamy but without the attendant genetic possibilities involved in fertilization.

Furthermore, so-called mating types exist in various ciliates. Thus in *Paramecium aurelia* six such types have been described, each type conjugating with its companion mating type but not with any of the others. When many animals of two companion mating types are mixed together, usually they soon become clumped in large groups which gradually are dispersed as the conjugating pairs swim away. The types are typically established at the reorganization of the exconjugants and are recognizable solely by their mating behaviour, which obviously differentiates the members of the species into physiologically incompatible genetical varieties from the standpoint of fertilization. Variations in mating types occur in other ciliates, involving both the number of types and of companion types for each. The significance of these types in regard to sex phenomena in general is not as yet clear, some authorities interpreting them as evidence of multiple sex systems.

The nuclei throughout the trophic life of most Protozoa contain the diploid number of chromosomes characteristic of the species. Reduction to the haploid condition occurs, as typically in the Metazoa, during the formation of the gametic nuclei, and their union restores the diploid number in the zygote. However, some instances are know, especially among the phytoflagellates and sporozoans, where reduction takes place immediately after fertilization so that only the zygote is diploid. (Fig. 9.)

Genetics.—Reproduction by division unaccompanied by fertilization, *i.e.*, uniparental reproduction, results as a rule in offspring with all their characteristics the same; collectively they constitute a clone. But there are some exceptions of great interest because the clone becomes differentiated into lines of descent with divergent characters. Some of these changes are physiological, such as acclimatization to various temperatures and chemicals, whereas others are morphological, such as size and shape. Some are adaptive and some are not. In certain cases the changes directly attributable to the influence of environmental conditions are inherited for hundreds of generations after the conditions leading to their establishment no longer are present, but in most instances, perhaps all, they gradually disappear. This supports the view that such so-called enduring modifications are chiefly cytoplasmic and are not established in the basic genetic system, as also does the fact that most of them are altered or disappear after sexual reproduction. But some of the heritable variations within a clone occur without obvious environmental influence, and long-continued selective breeding may isolate and establish different strains. Presumably these are the result of mutations, but how any of the changes during asexual reproduction actually arise is not as yet clear, although the fact remains that they form divergent lines of descent, some of which may be important in the differentiation of species.



FROM DOFLEIN, "PROTOZOENKUNDE" (FISCHER), AFTER KLEIN

FIG. 12.—VOLVOX SP. WITH FIVE DAUGHTER COLONIES PRODUCED ASEXUALLY. MAGNIFIED ABOUT 150 TIMES

However, the chief immediate source of variation arises, as would be expected, from sexual reproduction. In all of the diploid species, as well as in the relatively few haploid forms, inheritance, so far as known, follows the typical Mendelian principles and their extensions, involving segregation, independent assortment, dominance, linkage, crossing-over, etc. But, of course, there are no recessives in haploid species; the offspring manifest combinations of all the characters evident in the parents.

Furthermore, recent work with pedigreed cultures of *Paramecium aurelia* reveals definite proof of the interaction of specific dominant genes and cytoplasmic factors, both of which must be present if the character involved is to be expressed in the individual, or phenotype. The cytoplasmic element cannot be perpetuated in the absence of the dominant gene in the macronucleus, and the gene cannot initiate the synthesis of the cytoplasmic element. The latter has been referred to as a "primer" of the gene. Obviously this result offers highly significant data for the interpretation of so-called cytoplasmic inheritance in general.

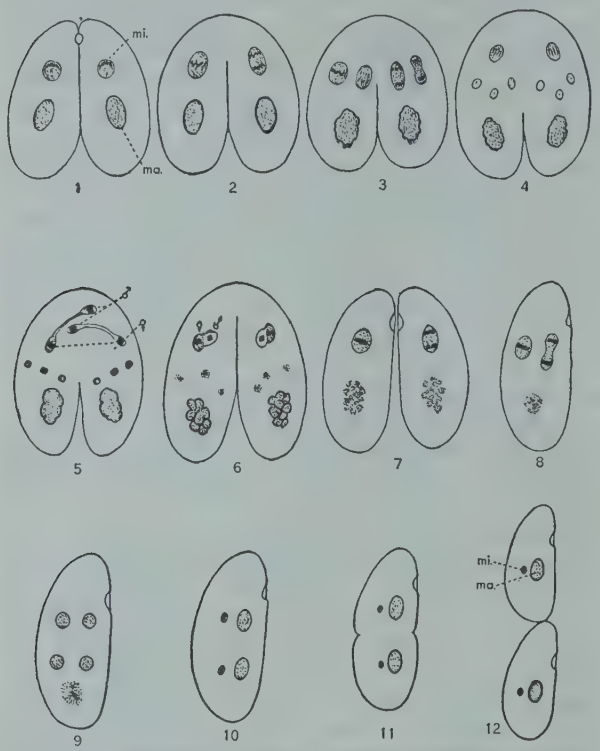
In brief, fertilization in the Protozoa, as elsewhere in animals and plants, produces hereditarily diverse strains from the two uniting gametes and thus is a source of variation that is of crucial importance in adaptation and evolution. And from the standpoint of evolution it is of great significance that the intrinsic genetic mechanism involved is the same from the Protozoa to the highest organisms, including man.

"Cycles."—In addition to its genetic results, fertilization contributes a dynamic effect that arises from the profound reorganization process involved. This aspect of fertilization has been widely studied in pedigreed races of many species of Protozoa ever since it was emphasized by the work of E. Maupas in 1888 and 1889, and elaborated by G. N. Calkins in a series of investigations begun in 1902. In general these studies on ciliates indicated that at conjugation there is initiated a cycle of reproductive activity. Thus after conjugation the rate of division rises for a considerable number of generations and then gradually wanes until death ensues unless the line is "rejuvenated" again by conjugation. This conclusion, if generally true, is of fundamental significance. But other work by various investigators has not only demonstrated that many species of Protozoa, in which fertilization normally occurs, can live under favourable environmental conditions in pedigreed cultures for many years and thousands of generations—apparently indefinitely—when fertilization is excluded, but also has revealed that there are others in which fertilization evidently does not occur at all in the life history. Therefore it is clear that basically fertilization is not a necessary phenomenon to counteract a general inherent tendency to degeneration and death in the Protozoa; and this is in agreement with the apparently limitless vegetative propagation of many plants and the greatly extended life of body cells of higher animals when cultivated *in vitro*.

Granting that fertilization in the Protozoa is not intrinsically indispensable, extensive experiments nevertheless have shown, particularly in the ciliates *Uroleptus* and *Spathidium*, that when conjugation does occur it actually produces a stimulation of the cell, especially evident in its rate of reproduction. Accordingly the dynamic aspect of conjugation may be of crucial importance—indeed have a survival value—when the organisms are exposed to unfavourable conditions. And the same result probably follows self-fertilization (autogamy), and also endomixis which involves nuclear reorganization without synkaryon formation.

Regeneration.—The power of replacing portions of the cell and specific organelles not carried over at the time of binary fission is, of course, universal in the Protozoa, but nearly equally so is the capacity to regenerate parts lost by mutilations of various kinds at other times in the life of the organism. Both processes are basically similar, involving dedifferentiation, growth, differentiation and reorganization. The animal may retain and remodel

old structures, or discard and replace them in a great variety of ways. In some instances a very small amount of cytoplasm with a nucleus suffices for a complete restoration of form. Indeed, under favourable conditions in some of the ciliates, *e.g., Spathidium,* a complete individual capable of division may regenerate from a nucleated piece comprising less than 10% of the original volume of the individual, while much less than this amount may



FROM TURNER, "FERTILIZATION IN PROTOZOA," IN CALKINS AND SUMMERS, EDS., PROTOZOA IN BIOLOGICAL RESEARCH (COLUMBIA UNIV. PRESS)

FIG. 13.—GENERAL PLAN OF CONJUGATION IN CILIATES

1, two individuals joined ventrally, micronuclei in early mitosis; 2, first meiotic (equation) division; 3, second meiotic (reduction) division, macronucleus beginning to degenerate; 4, third division of one of the nuclei in each animal to form the gametic nuclei; 5, exchange of the male (♂) gametic nuclei; 6, fusion of gametic nuclei to form synkaryon and restore diploid condition; 7, conjugants separate, first division of synkaryon; 8, second division of synkaryon; 9, four nuclei produced by the two divisions of the synkaryon, the old macronucleus disintegrates; 10, two of the four nuclei develop into new micronuclei, two into new macronuclei; 11 and 12, first fission of the exconjugant distributes one micronucleus and one macronucleus to each daughter cell, re-establishing the vegetative condition.

suffice for restoration of form without the ability to reproduce. But many other factors besides size and the presence or absence of the nucleus influence the result; among them being the part of the cell involved, the relative amount of ectoplasm and endoplasm present, the phase in the life history, etc. Although a nucleus is necessary in all cases for complete regeneration followed by normal fission, enucleated fragments may survive many hours or until destructive metabolic processes gain ascendancy. In the ciliates either a micronucleus or part of the macronucleus must remain if complete regeneration and reproduction are to occur. Amicronucleate races which are commonly found in some species possess the same power of regeneration as do typical micronucleate individuals.

Behaviour.—All Protozoa, of course, respond to many environmental factors. The reception of stimuli occurs in general over the entire surface of the cell, but sometimes special receptors are also present. Apparently pseudopodia, flagella, cilia, cirri, etc., act as tactile organs and probably as chemical receptors, but the most specialized sensory structures are photoreceptors such as the stigma, or eye spot, of many chlorophyll-bearing flagellates, represented by the various species of *Euglena* and *Volvox.* In the latter the organelle consists of a cup of pigment surrounding a photosensitive substance, and a lenslike structure near the opening of the cup. Evidence indicates that the lens brings certain light waves to a focus on the photosensitive material. More remarkable still is the eyelike apparatus of certain Dinoflagellates which is provided with a large spherical lens.

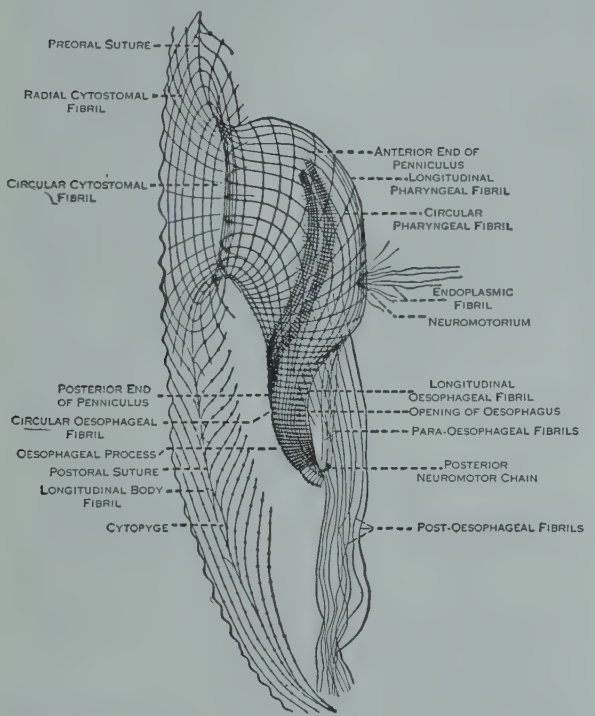
The effect of stimulation in most cases is conducted by the entire cell, but at least in certain ciliates, such as *Epidinium* (*Diplodinium*), *Euplotes* and *Paramecium,* a so-called neuromotor system of conducting fibres is found. This system is integrated with the general supporting ectoplasmic fibrillar network and specifically comprises a complex of fibres that ramify from a focus, or motorium, near the gullet and terminate at the basal bodies of the cilia or cirri. Experiments indicate that the system has a conductile function, because severance of the relationship of the fibres with the motor organs results in the loss of co-ordinated movement by the latter. (Fig. 14.)

Motor responses to particular agents are referred to as chemotaxis, thermotaxis, phototaxis, galvanotaxis, etc., in accordance with the nature of stimulus involved. Apparently in actively motile forms the reactions to stimuli are of two general but related types, one involving the trial and error method and the other directive action. In the former type of motor reaction an animal when stimulated stops and retreats, then turns at an angle to its previous course and proceeds again. And this avoiding reaction, or shock reaction, is repeated until, if possible, the animal is removed from the stimulating agent. In general, unfavourable stimuli induce responses whereas favourable ones do not, and accordingly the animals tend to collect where optimal conditions prevail; the reactions, though negative, are in the long run adaptive. In contrast to such responses, directive reactions are relatively rare and, indeed, intrinsically may involve shock reactions although the organism moves toward or away from the stimulus. They are best exhibited in the response of some chlorophyll-bearing flagellates to light, and of various species to electric currents. Changes in the intensity or direction of light rays so affect the stigma that by a series of responses the organism becomes oriented with its long axis parallel with the beam of light. If the anterior end of the cell is oriented toward the source of light, progression is in that direction. Such positive phototaxis is usual in the green flagellates, but is subject to modification by various factors, such as abrupt changes in the intensity of the light or the chemical condition of the environment; as indeed are all reactions of the Protozoa. Most Protozoa exhibit galvanotaxis by directive responses to the passage of an electric current. Amoebae extend pseudopodia toward the cathode and move in that direction. Flagellates usually proceed toward the anode and ciliates toward the cathode, largely as a result of the direct action of the current on the locomotor organs. Accordingly, when certain flagellates and ciliates are intermingled on a slide under the microscope, they can be separated by the passage of a constant current —anodically galvanotactic flagellates moving to one pole and cathodically galvanotactic ciliates to the other. Then if the current is reversed the two groups rush toward each other, pass and again assemble at opposite poles.

But the behaviour of the Protozoa is not so stereotyped as might appear from the relatively simple reactions just mentioned. In certain cases these may be integrated so that the animals exhibit potentialities beyond those of mere automata. This condition may be glimpsed if a ciliate, *Stentor roeseli,* while sessile is stimulated by a tiny stream of carmine grains. In general, when the useless carmine first reaches the peristome no reaction occurs, but as the carmine continues, the animal bends over to one side. If this behaviour does not remove the stimulus, the ciliary beat is temporarily reversed so that the carmine momentarily does not reach the oral apparatus. And, if the stimulus still continues, the organism contracts more or less violently and, finally, becomes detached and swims away. Furthermore, when a *Stentor* which has reached the contraction stage in the series of reactions is stimulated again within a few minutes, it does not run the gamut of responses but immediately contracts. Obviously a series of different physiological states has been initiated, since the animal

successively responds in a different manner to the same stimulus. Behaviour is modifiable.

Explosive Organelles.—Prominent among the various specialized organelles that contribute to the versatility of the protozoan cell are trichocysts and similar explosive structure. Trichocysts occur in many ciliates and have been most intensively studied in *Paramecium*, where they are quite evenly distributed



FROM LUND (UNIV. OF CALIF. PUBL. ZOOL., VOL. 39, P. 48, FIG. A)

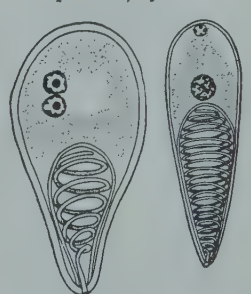
FIG. 14.—DIAGRAM OF THE NEUROMOTOR SYSTEM IN THE PERISTOMIAL REGION OF PARAMECIUM MULTIMICRONUCLEATUM. VERY HIGHLY MAGNIFIED

just beneath the surface of the cell. Each trichocyst is a minute, spindle-shaped body which, on mechanical or chemical stimulation, ejects material that instantaneously forms a relatively long filament projecting from the cell. The function of the threads has not been determined but probably is protective. Exploded trichocysts may be replaced by new ones. More complex trichocysts, called cnidotrichocysts, occur in other species, for example the ciliate *Prorodon*, where they consist of a capsule containing a coiled tube which on discharge is everted and apparently passes material to the exterior. Indeed in some species it is evident that toxic material is secreted because free-swimming prey is paralyzed upon contact with the oral region to which the trichocysts are confined. Cnidotrichocysts closely approach in structure the nematocysts of coelenterates, as is evidenced by the fact that especially complex examples found in two genera of dinoflagellates were formerly regarded as ingested nematocysts. Again, an immense group of the Sporozoa is known as the Cnidosporidia because the highly specialized spores are characterized by so-called polar capsules, each containing a spirally-wound thread that evaginates and apparently serves as an anchor when the proper position is attained in a new host. The diversity of structure and function of explosive organelles makes it obvious that they have evolved independently in different groups of Protozoa. (Fig. 15.)

Encystment.—Many species of Protozoa have the ability to seal themselves in essentially impermeable cases, or cysts, to meet various exigencies of the environment or to carry on digestion and reproduction. So-called protective cysts enable the organism to withstand desiccation, lack of food and other conditions inimical to active life and are most common in fresh-water and parasitic forms. The general procedure of encystment in free-living species, such as many ciliates, involves a complex series of events. The animal becomes quiescent while cilia, flagella, and other organelles not absolutely essential for life are resorbed, and food and inert material are ejected. Contractile vacuoles function more and more slowly and finally disappear as water is eliminated and the body becomes a relatively small sphere. While this dedifferentiation is proceeding, the cyst wall is secreted which commonly consists of an outer gelatinous layer, or ectocyst, and an inner delicate membrane, or endocyst, but there is great variation in composition and structure. The ectocyst rapidly hardens and frequently has characteristic spines, warts, etc. Within this resistant case the dormant animal, with all life processes reduced to a minimum, can survive unfavourable conditions for long periods of time. Thus cysts in samples of dry soils, tightly bottled, have yielded the ciliate *Colpoda* after 38 years, and small amoebae and flagellates after 49 years, when supplied with culture fluid; but the evidence indicates that most ciliates encysted on dry hay rarely survive more than five years. The process of excystment is broadly the reverse of encystment and is initiated by the presence of moisture or, if the cysts are already in water, by the return of favourable temperature, chemical conditions and the presence of food. The endocyst is dissolved by enzyme action induced by the animal, which thereupon ruptures the ectocyst and escapes to assume its typical form.

The world-wide distribution of many of the Protozoa is probably dependent to a large extent upon their ability to encyst, which enables them to be transported in numerous ways, such as by adhering to the feet of birds or to dry grass, and by being wafted by air currents. However, results obtained from the exposure of sterile culture media to the atmosphere indicates that only a relatively few species are usually disseminated in the air: chiefly tiny amoebae and flagellates and the ciliate *Colpoda*. And, incidentally, there is no completely satisfying evidence that the cosmopolitan *Paramecium* encysts, in spite of the prevalent notion that a culture can be established by the infusion of dry hay in sterile water.

In many parasitic forms, notably the Sporozoa, cysts are crucial in order that the parasite may weather the outside world during chance transfer to a new host. Indeed, the absence of protected stages during a parasite's life history usually indicates that it is directly transferred by an intermediate host. Many of the highly specialized protective cysts of parasites are also reproduction cysts because spore formation and other types of multiplication occur in them. Encystment in such cases does not involve a dedifferentiation of the animal but rather its specialization for the reproductive process. Furthermore, various free-living species encyst for reproduction, fertilization or simply to digest a heavy meal. In the life history of the foraminiferan *Patellina corrugata* growth cysts, fission cysts and fertilization cysts occur in sequence. Obviously, then, protozoan cysts serve such various functions, sometimes several simultaneously, that it is often impossible to distinguish sharply among the many types.



FROM CALKINS, "BIOLOGY OF THE PROTOZOA" (LEA & FEBIGER), AFTER KUDO

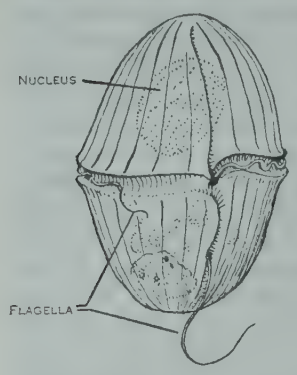
FIG. 15.—CNIDOSPORIDIAN SPORES WITH POLAR CAPSULES. VERY HIGHLY MAGNIFIED

DISTRIBUTION

Protozoa are essentially ubiquitous wherever moisture is available, but certain species are, of course, adapted to special habitats so that characteristic faunas develop. Excluding for the moment parasitic species that constitute highly specialized groups within nearly all higher animals and some plants, a few representative examples of marine and fresh-water faunas will serve as examples, but it must be borne in mind that each of these major

faunas is, in turn, formed of numerous relatively local faunal groups.

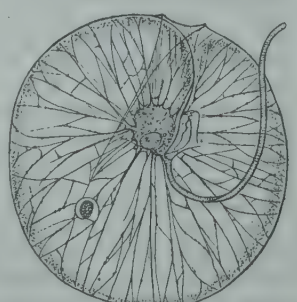
Among the flagellates the order Dinoflagellata stands pre-eminent in its contribution to the microscopic life of the sea. Typical dinoflagellates possess two flagella, usually lodged in grooves, one encircling the body and the other trailing posteriorly. Nutrition is commonly autotrophic through the presence of chromatophores, but many holozoic and parasitic species occur, and some of the zooxanthellae in the Radiolaria and Foraminifera are apparently symbiotic dinoflagellates. Although some species abound in fresh waters and are troublesome in municipal reservoirs, they are inconsequential in comparison with those constituting the marine fauna which plays an important part in the nutrition of oceanic life as a whole. This is chiefly because of photosynthetic activity that makes many species a first link in the nutritional chain and so an integral part of the so-called ocean pastures; but some species exist in such prodigious numbers that they directly constitute a significant part of the food of tiny invertebrates and so indirectly of higher animals. Vast areas of the sea may be discoloured by their presence; thus not infrequently the water appears orange like "tomato soup" from the presence of incalculable numbers of the cosmopolitan *Noctiluca miliaris*, and the same organism is responsible for much of the luminescence of marine waters. (Figs. 16, 17.)



FROM WOODRUFF, "FOUNDATIONS OF BIOLOGY" (MACMILLAN)

FIG. 16.—A DINOFLAGELLATE, GYMNODINIUM SP. MAGNIFIED ABOUT 500 TIMES

The great contributions of the rhizopods to the microfauna of the sea are made by the Foraminifera and the Radiolaria. Most species of the former are bottom-dwellers that creep on the surface of the mud and ooze or attach themselves loosely to foreign material, but pelagic species are represented by enormous numbers of individuals. The shells, composed chiefly of calcium carbonate, sink to the bottom and contribute to the Globigerina ooze, so called because of the predominance of members of the Globigerinidae and closely related forms. This and similar deposits cover vast areas—perhaps one third of all the ocean floor down to approximately 5,000 yd.—and have been computed to be accumulating in certain regions at the rate of about 12 mm. in 1,000 years. At greater depths other species with arenaceous shells persist. Deposits during the geologic past are represented today by limestone, as seen in the chalk cliffs of England. Various types have rather definite geologic and geographic ranges and therefore are of significance in determining the age and characters of sediments and the general conditions under which they were laid down. Such knowledge is of great value in checking well-drillings and accordingly in locating oil-bearing strata. (Fig. 5.)



FROM PRATJE, "ARCHIV F. PROTISTENKUNDE" (FISCHER)

FIG. 17.—NOCTILUCA MILIARIS. MAGNIFIED ABOUT 50 TIMES

Although a few species of the Foraminifera inhabit fresh and brackish water, the Radiolaria are solely marine and adapted to a pelagic life. The body is typically spherical or conical and is usually supported by a silicious skeleton in a bewildering array of beautiful patterns. The distribution of the group as a whole is very extensive, both horizontally and vertically, and the skeletons accumulate in the great depths of the sea where calcareous shells of other forms become dissolved. Here in association with sponge spicules, diatom tests, and so on, they form the chief element of the Radiolarian ooze. And in the geologic past their skeletons have made large contributions to silicious rock. (Fig. 7.)

The ciliate fauna of ocean waters is by no means inconsequential, but it is not comparable in importance with those of the flagellates and rhizopods. Most typical is the wealth of marine species and individuals of the Tintinnidae, pelagic heterotrichous forms provided with vaselike protective cases consisting chiefly of a secreted organic material moulded into widely divergent but specific patterns.

As to the more varied conditions afforded by bodies of fresh water, it is impossible even to summarize the distribution of large groups of Protozoa in such broad terms. Members of the three free-living classes flourish everywhere in puddle, pond and lake, and some occur in hot springs and Arctic waters. Most of the common species abound in similar places the world over. Many species are remarkably adaptable, being equally at home in fresh or brackish water or even in the sea. Although this is true, very slight variations in conditions, particularly the type of available food and the chemical constituents of the environment, determine the presence or absence of certain species. For instance, *Paramecium* feeds chiefly on bacteria, and *Didinium* solely on *Paramecium*, so that depletion of the bacteria eventuates in the encystment of *Didinium*. This interdependence seems relatively clear-cut, but it involves various other factors not immediately apparent.

The practical impossibility of analyzing many of the elements involved in the "web of life," even in a relatively restricted environment, is well exhibited by the general development of an infusion of a few wisps of hay and water. Here the obvious components merely supply the matter and energy for the interplay of various micro-organisms present in a dormant or active state on the hay or in the water. A microscopical examination of a newly-made infusion shows very few active organisms, but if the temperature is favourable countless bacteria arise in a day or so from the relatively small number originally present. Then during the period of bacterial ascendancy another factor intrudes itself: microscopic animals, chiefly Protozoa that have been multiplying with increasing rapidity as conditions became more favourable, soon become the dominant life phase in the infusion. Usually first to appear are various species of minute flagellates, some saprozoic and others holozoic, that employ the products of organic disintegration supplied by the activity of the bacteria and the bacteria themselves. Then tiny ciliates, such as *Colpidium* and *Colpoda* appear in countless numbers and feed on the bacteria. This dominance of small ciliates is terminated after a time by the ascendancy of larger ciliates which, though feeding to some extent on the now greatly depleted bacterial population, employ chiefly the smaller Protozoa as food. And so the general nutritional cycle in the infusion continues with attendant chemical changes; saprozoic species are gradually replaced in dominance by herbivorous types, and these in turn by others that are carnivorous. But clearly this sequence of events must sooner or later terminate; extermination faces the population unless chlorophyll-bearing organisms are present to entrap and store the energy of sunlight—to form food photosynthetically. If such occurs, the hay infusion world is, indeed, a microcosm in which the various Protozoa and other organisms are reciprocally adjusted so that essentially a stable equilibrium results. (Fig. 11.)

Most free-living Protozoa find larger and relatively stable bodies of water conducive to their welfare, but specialized conditions do not always exclude them. Thus various species inhabit the fluid in the traps of carnivorous plants, such as the bladders of *Utricularia* and the pitchers of *Sarracenia*, and others flourish in the water in holes in trees. Most of these species are incidental sojourners but some apparently are especially adapted to the microclimatic factors in such unique environments. Indeed, the examination of blades of grass moist with dew usually reveals certain species making the most of a brief opportunity for activity before returning to the encysted state. And within the soil an immense fauna of Protozoa contributes to soil microbiology in association with bacteria and other fungi, algae, and various lower

animals. It appears that the majority of the Protozoa present are essentially cosmopolitan in distribution from the arctic regions to the tropics, though there are certain dominant types in nearly every soil. Most protozoan forms are found in the upper six inches of soil, but large numbers may be several feet below the surface. In general the number of species and individuals present is in direct proportion to the number of bacteria, being most numerous in rich, moist soils. Some idea of the size of the population may be gained from the fact that in one study it was estimated that at the maximum there were more than a million amoebae and flagellates per gram of soil. The view has been urged that the Protozoa may be inimical to soil fertility by destroying types of bacteria important for crop growth. This remains to be proved; but that the Protozoa form an important, active element in the soil microcosm is certainly true, even though many are in the encysted condition for considerable periods. Again here it seems clear that among the various species present some are mere casual inhabitants, while others constitute an endemic soil fauna. And in passing it should be noted that various Protozoa play a part in the so-called self-purification of streams by depleting the bacterial population, whereas others add to the contamination of municipal water supplies chiefly by liberating oily products of metabolism which impart odours to the water that may render it unpalatable. In brief, the adaptability of the Protozoa is so great that they have left hardly a niche in nature untenanted—not even in the bodies of other organisms.

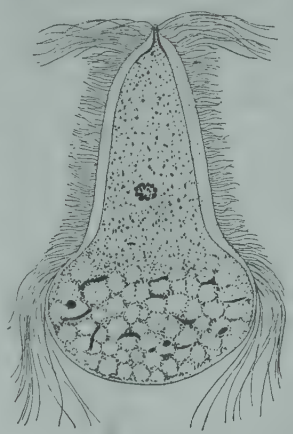
PARASITISM

The intimate association of Protozoa with other animals as commensals, symbionts, or parasites is widespread, but often it is difficult to distinguish between these types of relationship because one may grade into the other, or the same species may act in different capacities under varying conditions. Commensal associations incur no injury to either species involved, the protozoon merely gleaning food as a result of its position on the surface or in the interior of its host. Common ectocommensals among the ciliates are various vorticellids and suctorians attached to hydroids, and *Kerona* and *Trichodina* that crawl on *Hydra*. Endocommensals are more numerous, being widely distributed especially in the digestive tract of higher animals. Among them are most of the bizarre faunas of ciliates that inhabit the stomach or intestine of various herbivorous mammals, such as sheep, cattle and horses; and some of the flagellates and amoebae present in the human intestinal tract.

Symbiotic species, in which the relationship is mutually beneficial, are relatively few but include interesting examples. Thus the common *Paramecium bursaria* harbours unicellular green forms, or zoochlorellae, in its endoplasm where they multiply and, in return for a relatively safe abode and waste products of metabolism, supply the products of photosynthesis when light is available. Again an immense number of highly specialized flagellates, such as the various species of *Trichonympha* and their allies, dwell in the intestines of certain termites and wood-feeding roaches where they secrete enzymes that digest cellulose and thus make the products available to their hosts. If the flagellates are removed the insects die of starvation. And at least a few of the ciliates mentioned above that inhabit the digestive tract of cattle apparently perform a similar function, although here digestion of cellulose is dependent chiefly upon bacteria. Furthermore, in these and other cases where the protozoan fauna is enormous it may well be that it directly affords an appreciable increment to the nitrogenous food supply of the host. (Fig. 18.)

Associations in which one organism, the parasite, secures the sole advantage at the expense of the hapless host are by far the most numerous. As already mentioned, protozoan parasites have been found in nearly all higher animals that have been investigated, and they also occur in some plants. Even the Protozoa themselves are not immune. Thus a species of amoeba infests the endoplasm of certain opalinid ciliates which, in turn, live in the frog—an example of hyperparasitism.

The most intensively studied protozoan parasites are naturally those which produce serious maladies in man, in particular the malarial organisms, trypanosomes, and endamoebae. The human malarial parasites are members of a large group of the Sporozoa that are known as Haemosporidia because a part of the life history is spent in the blood of vertebrates. Very closely related to the malarial forms in man are those that parasitize birds, and their study has contributed largely to the knowledge of malaria in general. Four species of human malarial parasites had been recognized by 1945, three of them being outstanding in importance: *Plasmodium vivax,* the cause of so-called benign tertian malaria, *P. falciparum* of malignant tertian malaria, and *P. malariae* of quartan malaria. *P. ovale* also produces a benign type of tertian malaria. The life histories of all four species follow a similar general basic plan with a mosquito of the genus *Anopheles* as the invertebrate host. Asexual stages (sporozoites) inoculated by a mosquito into the human blood stream multiply in the red blood cells and probably also in the reticulo-endothelial tissues. Eventually gamete-forming stages (gametocytes) arise which demand transfer from the peripheral blood to a mosquito for further development. If this hazard is met, gametes develop and fertilization occurs in the stomach of the mosquito and then the motile zygote enters the stomach wall and forms a large oocyst within which myriads of sporozoites are formed. Rupturing of the oocyst releases the sporozoites into the body cavity from whence they reach the salivary glands of the mosquito, ready to be inoculated into man. (Fig. 4.)



FROM CALKINS, "BIOLOGY OF THE PROTOZOA" (LEA & FEBIGER), AFTER KOFOID & SWEZY

FIG. 18.—TRICHONYMPHA CAMPANULA. MAGNIFIED ABOUT 300 TIMES

The most important parasitic flagellates are members of the genus *Trypanosoma* that infest chiefly the blood stream of various vertebrates, including man, usually after a cycle of development in blood-sucking invertebrates. Trypanosomes show considerable change in form during the life history, but the typical "adult" phase found in the vertebrate circulatory system is an elongated bladelike organism, with the flagellum arising from a basal body near the posterior end of the animal and then passing forward as the edge of a delicate undulating membrane to emerge at the anterior end as a free flagellum.

The most important pathogenic forms in man are *Trypanosoma gambiensi,* the causative agent of typical African sleeping sickness, and *T. rhodesiensi,* which produces a similar but still more virulent effect. Both species are morphologically indistinguishable from each other and from *T. brucei,* which does not infect man but is the cause of "nagana" in domestic cattle of tropical Africa. All three are transmitted by tsetse flies and apparently are nonpathogenic in their natural reservoirs, certain antelopes and other wild mammals, and are essentially physiological races of one species. Another human trypanosome of high significance is *T. cruzi,* the cause of Chagas' disease, which is chiefly prevalent in Central and South America. The parasite is transmitted by triatomid bugs and multiplies in various organs of the human body. Most trypanosomes cause little disturbance in their natural hosts; for example, *T. theileri,* transmitted to cattle by tabinid flies and *T. lewisi,* to rats by fleas. The vectors of the trypanosomes of aquatic vertebrates are usually leeches, as in the case of *T. rotatorium* of the frog. (Fig. 19.)

Among the rhizopods that infest man the only true parasite is *Endamoeba histolytica,* formerly believed to be confined to tropical regions but now known to be cosmopolitan in distribution. The other five species are harmless commensals, although *E. gingivalis* of the mouth may take advantage of otherwise infected gums, and is apparently transmitted by contact because cysts are unknown. In the case of *E. histolytica,* encysted stages reach the

human intestine, usually in contaminated water or food, where excystment occurs, and the amoebae multiply in lesions they produce in the wall of the colon. In many cases no observable pathological symptoms follow while the amoebae produce a continuous supply of cysts which pass to the outer world, ready to infect another host. The evacuation by the host of more than 40,000 cysts in one day has been recorded. But sometimes this

relatively innocuous host-parasite relationship does not prevail, either because of the particular sensitivity of the host or the special virulence of the race of amoeba involved. Then the latter become highly destructive parasites that produce serious lesions in the tissues of the colon, resulting in "amoebic dysentery." In addition the parasites pass to other organs of the body, most often forming abscesses in the liver. Incidentally, this procedure is equally unfortunate for the amoebae, since the progeny are rarely able to encyst and make a getaway to another host. (Fig. 20.)

TAXONOMY

Classification of the Protozoa offers especial difficulties, chiefly because all the variations occur within the confines of a single cell or a series of cells comprising a life cycle, whereas in other animal phyla the numerous characters of multicellular bodies combine to afford more easily discernible diagnostic features. Accordingly, taxonomic systems are to a considerable extent more tentative in the Protozoa than elsewhere in the animal kingdom. However, it is believed that the following brief classification approximates the consensus of opinion of protozoologists and will serve to give a synoptic view of the phylum. It must be emphasized, however, that the versatility of the Protozoa is so great that only the most salient characters of representative types can be cited.

PHYLUM PROTOZOA. Typically unicellular animals that stand in contrast with the rest of the animal kingdom, the multicellular animals, or Metazoa. Four classes are recognized:

Class I. MASTIGOPHORA or FLAGELLATA. The most primitive of the four great classes of Protozoa, comprising animals with one to many flagella in the principal phase of the life history. The typical form is ovate or elongate with a cortex which maintains a definite shape, but there is immense variation and some species are even temporarily amoeboid. Division is almost always longitudinal. Habitats and methods of nutrition are highly diverse; most species are free-living, but many are parasitic.

Subclass PHYTOMASTIGOPHORA. A large assemblage of the most primitive members of the class, some of which can, with reason, be classified as plants. Many species assume a so-called palmella phase in which the cells lose their flagella, round up, and secrete a gelatinous matrix in which they reproduce. Nutrition is usually autotrophic, but many species are saprozoic and some are holozoic at various phases of their life history. They are widely distributed in fresh and salt water.

Order *Chrysomonadida.* Usually small, simple forms, with one or two apical flagella, yellow or brown chromatophores, and often a red stigma. Many are remarkably protean, readily assuming amoeboid and palmella phases. In some species the palmella state is dominant. Nutrition is usually autotrophic, but may be saprozoic or holozoic. Coverings of cellulose and silica are common. So-called coccoliths, common in ocean sediments, are plates of calcium carbonate from the tests of one widely distributed family of this order. Unique silicious cysts are characteristic of the group. Representative genera are *Chromulina, Mallomonas,* and *Dinobryon,* the last usually colonial, and *Synura* and *Uroglena,* both colonial.

Order *Cryptomonadida.* Tiny flagellates with a relatively constant body form and one or two flagella, usually inserted at the anterior end of a furrow which in some species leads into a cytopharynx. Chromatophores may be yellow, brown, blue or green; but there are many colourless species that are either saprozoic or holozoic. Palmella stages occur. Some cryptomonads live as symbiotic zooxanthellae in other protozoons and in metazoons. Typical genera are *Cryptomonas* (with yellow chromatophores) and *Chilomonas* (colourless).

Order *Dinoflagellida.* A large but relatively circumscribed group; the characteristic type possesses two flagella, disposed in grooves, one of which forms a girdle while the other trails. Most species are provided with tests composed of one or numerous cellulose plates impregnated with inorganic material, but many are naked. Chromatophores are usually yellow or brown. Nutrition is autotrophic, saprozoic or holozoic. Departures from the typical body-plan are numerous, while symbiotic and parasitic species may lose all characteristic structure but form flagellated "dinospores." Representative genera are *Gymnodinium, Glenodinium, Peridinium, Ceratium* and *Blastodinium* (parasitic). The well-known *Noctiluca miliaris,* attaining about 1.5 mm. in diam., is an aberrant, floating, marine species with one small flagellum and a so-called tentacle. It was formerly assigned to a special group, the Cystoflagellata. (Figs. 16, 17.)

Order *Euglenida.* A wealth of common species, usually spindle-shaped, with one or two flagella emerging from a pit or pharynx into which a contractile vacuole discharges. A red stigma is present in the chlorophyll-bearing forms. Some species are very plastic and exhibit "euglenoid movements." Nutrition is autotrophic, saprozoic or holozoic. Encystment commonly occurs, and palmella phases are present in some species. Well-known genera include *Euglena* (green, one flagellum), *Astasia* (colourless, one flagellum), *Heteronema* and *Peranema* (colourless, two flagella). (Fig. 3.)

Order *Chloromonadida.* A largely artificial group comprising relatively rare and little-known species, usually with two flagella and small pale green chromatophores. Representative genera are *Gonyostomum* and *Vacuolaria.*

Order *Phytomonadida.* Typically small, ovate or spindle-shaped cells usually with two flagella, a red stigma and green chromatophores. Many of the phytomonads are colonial. Sexual reproduction is general with isogamous or anisogamous gametes. Common representatives of the noncolonial forms are the many species of *Chlamydomonas,* in a few of which haematochrome develops abundantly under certain conditions so that the organisms impart

a reddish tinge to melting snow, rain pools, etc. Some genera, such as *Polytoma,* comprise colourless, saprozoic forms. The family Volvocidae includes the highly interesting colonial types, represented, for example by various species of *Gonium, Pandorina, Eudorina, Pleodorina* and *Volvox.* The individual zooids are, in general, Chlamydomonas-like in form and vary in number from 4 in *Gonium* to many thousands in *Volvox.* (Fig. 12.)

FROM DOBELL, "THE AMOEBAE LIVING IN MAN" (WILLIAM WOOD & CO., 1919)

FIG. 20.—ENDAMOEBA HISTOLYTICA, SHOWING NUCLEUS AND THREE INGESTED RED BLOOD CELLS. MAGNIFIED VERY HIGHLY

Subclass Zoomastigophora. Flagellates without chlorophyll and unequivocally animal in nature, showing an immense structural range from simple to complex. Nutrition is holozoic or saprozoic. Many species are parasitic.

Order *Protomastigida.* Some of the simpler representatives, often referred to as monads, are tiny ovate forms, usually with one or two flagella, but with some amoeboid tendencies. Free, attached, and colonial species occur. Common genera include *Monas, Oicomonas* and *Anthophysa* (colonial). Members of the genus *Bodo,* with one flagellum directed anteriorly and the other trailing, are examples of somewhat more complex forms, usually possessing a cytostome, multiple basal bodies and a parabasal body near the flagellar insertion. In the genus *Cercomonas* the trailing flagellum passes along the cell surface and becomes free merely at the posterior end, whereas in *Cryptobia* (*Trypanoplasma*) it forms the edge of an undulating membrane so that these parasites superficially resemble Trypanosomes. In one group, the Choanoflagellates, the animals have a delicate cytoplasmic collar about the base of the single flagellum that aids in catching food. The remarkable similarity of these flagellates to the collar cells of sponges and the fact that a colonial representative, *Proterospongia,* forms a gelatinous mass with both collar and amoeboid zooids suggest a possible point of origin of the Porifera, or sponges.

But by far the most significant members of the Protomastigida from the standpoint of human welfare are members of the family Trypanosomidae which comprises a remarkable series of parasitic species. In general they are fusiform or bladelike cells with or without an undulating membrane connecting a part of the single flagellum with the cell surface, but all are highly polymorphic. Three genera, *Leptomonas, Phytomonas* and *Leishmania,* are very similar in the flagellate phase, with the flagellum arising from a kinetic complex at the anterior end. The leptomonads are confined to invertebrates and chiefly to insect hosts, but the phytomonads are transmitted by insects to the latex of certain plants and the leishmanias to vertebrates. In the vertebrate host leishmania loses the flagellum and rounds up as an intracellular parasite that gives rise to characteristic pathological symptoms; for example, one species produces in man the disease known as "kala azar," and another "Oriental sore." The members of the genera *Crithidia* and *Herpetomonas* are restricted to invertebrates and are similar in structure to the genera mentioned above, but with the flagellum arising further posteriorly and extending forward as the edge of a small undulating membrane. Finally, in the genus *Trypanosoma* the flagellum arises near the posterior end and proceeds forward as the edge of an extensive undulating membrane. Trypanosomes are blood-inhabiting parasites of man and other vertebrates, with an invertebrate, usually an insect or leech, as the intermediate host. The trend of evolution in the family is indicated by the progressive polymorphism exhibited by the several genera that reaches a climax in the trypanosomes whose life history recapitulates, as it were, the phases that are dominant in the other genera. (Fig. 19.)

Order *Polymastigida.* An assemblage of diverse forms usually with from three to eight flagella but sometimes with many. The majority of the species are parasites or commensals in the intestinal tract of animals. Among the simpler genera commonly represented by species in man are: *Trichomonas* with one nucleus and four anterior flagella and another flagellum which forms the edge of an undulating membrane; *Chilomastix,* with a single nucleus and four flagella, one of which undulates in a cytostomal cleft; and *Giardia,* with two nuclei and eight flagella arising from three parts of a bilaterally symmetrical body. It is not clear that any of the species are primarily pathogenic, though when present in large numbers they may aggravate abnormal conditions. The most complex polymastigotes live as commensals or symbionts in the intestine of termites and exhibit a reduplication of certain structures of the simpler species so that there may be many nuclei, each associated with several flagella, a parabasal body and other kinetic elements. Examples are *Calonympha* and *Stephanonympha.*

Order *Hypermastigida.* The acme of flagellate complexity is attained in this order, which includes a wealth of commensal and symbiotic forms chiefly in termites and cockroaches. They possess numerous flagella, either widely distributed or in tufts, and a multiplication of kinetic structures but only one nucleus. Regional differentiation of the cytoplasm is remarkable. The origin of the diversity and high specialization of the unique populations of hypermastigote and polymastigote flagellates in a restricted environment is of considerable evolutionary interest. Common examples are *Lophomonas blattarum,* found in domestic cockroaches, and various species of *Trichonympha,* present in termites and wood roaches. (Fig. 18.)

Order *Rhizomastigida.* A heterogeneous group of species that may almost equally well be included under the class Sarcodina because they are essentially amoebae with one or more permanent flagella. The best-known genus is *Mastigamoeba.*

Class Sarcodina or Rhizopoda. A huge assemblage of amoeboid animals formerly regarded as the most primitive class of the phylum. The chief general characteristic is the presence of pseudopodia for locomotion and obtaining food, though some temporarily develop flagella, and others produce flagellated gametes. Nutrition is usually holozoic.

Order *Amoebida.* The typical shell-less amoebae with pseudopodia varying from lobose to broad. Some of the simplest forms exhibit interchangeable amoeboid and flagellated phases. Among the larger fresh-water amoebae the best known is *Amoeba proteus* with lobose pseudopodia showing surface ridges, truncate bipyramidal crystals in the endoplasm, and a discoidal nucleus. Reproduction is apparently solely by binary fission. This species sometimes attains a length of more than 600 micra as it creeps along, but members of the genus *Pelomyxa* are very much larger and have many nuclei. One of the latter possibly was the amoeba observed by Rösel von Rosenhof as early as 1755 and named *Chaos chaos* by Linnaeus in 1767. In addition to the many free-living amoeba, large and small, there are numerous parasitic species, the one of outstanding importance being the widely distributed *Endamoeba histolytica,* the sole pathogenic amoeba inhabiting man. (Figs. 2, 20.)

Order *Testacea.* Amoebae with simple one-chambered tests of tectinous material in which foreign particles or secreted silicious plates are usually incorporated. The pseudopodia apparently consist solely of ectoplasm and are often threadlike. Reproduction is usually by the protrusion of a bud from the orifice of the test but, in certain cases, multiple division results in the liberation of many amoebulae that gradually assume the characters of the parent. Common representatives in fresh-water ponds and bogs are the many species of *Arcella* with yellowish, bowl-like tests, and *Difflugia* and *Euglypha* with pyriform tests. (Fig. 5.)

Order *Foraminifera.* An immense array of almost exclusively marine, shelled rhizopods of considerable importance. The shells may be tectinous, arenaceous, or silicious, but the majority are calcareous. They may consist of one or many chambers, and be imperforate or perforated by numerous tiny pores that afford, in addition to the mouth of the shell, exits for numerous fine branching and anastomosing pseudopodia. The multichambered (polythalamous) forms result from the addition to the initial chamber

of one new chamber after another and, in general, their shape and the spatial relations they assume determine the various types of shells as linear, spiral, etc. The life history typically involves an alternation of asexual and sexual generations with characteristic differences in the shells, nuclear apparatus, etc. The asexual generation produces amoeboid spores that develop into sexual individuals, while the latter give rise to amoeboid or flagellated gametes and the resulting zygotes develop into asexual individuals. Nearly 50 families had been recognized by 1945. Well-known genera include *Globigerina, Elphidium* (*Polystomella*), *Peneroplis, Patellina,* and *Camerina* (*Nummulites*), the last solely fossil. (Fig. 5.)

Order *Proteomyxa.* A relatively small heterogeneous assemblage of indefinite relationships, usually with raylike pseudopodia that frequently branch or tend to anastomose. Most species are parasites on the lower algae, such as *Spirogyra.* Representative genera include *Nuclearia, Arachnula* and *Vampyrella.*

Order *Mycetozoa.* An immense group sometimes classified among the Fungi as Myxomycetes, or "slime moulds," chiefly because, in the typical free-living species, specialized structures are developed for the production and dissemination of air-borne spores. Although this characteristic may be regarded with some assurance as an indication of convergence rather than of relationship with plants, the Mycetozoa are evidently a borderline group where formal classification is difficult or fails entirely. The most prominent phase in the life history consists of a multinucleate sheet of flowing protoplasm, the plasmodium, with great networks of anastomosing pseudopodia. Eventually spores are developed and these produce tiny amoeboid forms, each with a flagellum, that multiply and form gametes. The zygote is an amoeboid cell which increases in size by growth and union with other similar plasmodia, in some cases becoming several centimetres in diameter and containing thousands of nuclei. Nutrition is saprozoic and holozoic as the plasmodium creeps over decaying wood, leaves, etc. Common genera include *Lycogala, Physarum* and *Fuligo.* In addition to the typical Mycetozoa there are usually included in the group various forms which may be only distantly related because they exhibit wide departures in structure and life history. One of the most common is *Plasmodiophora brassicae,* an intracellular parasite which produces the disease known as clubroot in cabbages and closely related plants.

Order *Heliozoa.* A rather circumscribed group of typically spherical fresh-water forms with raylike axopodia. Protective coverings of gelatinous material, silicious spicules, etc., are often present. Most so-called sun animalcules are free-floating but some are sessile. Nutrition is holozoic. Common genera include *Actinophrys* (uninucleate) and *Actinosphaerium* (multinucleate). (Fig. 6.)

Order *Radiolaria.* An enormous assemblage of marine species adapted for pelagic life, including some of the largest Protozoa. Most are spherical and are provided with complex skeletons of remarkable and beautiful designs. The skeletons are usually silicious, but in one group they are apparently composed of strontium sulphate. The most highly characteristic feature is the definite segregation of the body into intracapsular and extracapsular regions by a perforated membrane, the central capsule. The intracapsular protoplasm is relatively homogeneous and includes from one to many nuclei, oil droplets, etc., while the extracapsular region is differentiated into several zones. The outermost consists largely of axopodia and myxopodia which have their origin within or just outside the central capsule in the surrounding "matrix" and traverse the broad "calymma": a gelatinous zone apparently secreted by the protoplasm and characterized by fluid-filled vacuoles that give the animal a frothy appearance. So-called yellow cells (zooxanthellae) are usually present in the calymma and in certain cases, at least, are modified dinoflagellates and chrysomonads living as symbionts or parasites. Reproduction by division includes the central capsule and, when possible, the skeleton. Multiple division of the nucleus and central capsule without division of the extracapsular protoplasm may give rise to temporary forms with several capsules, a condition that is permanent in some colonial species. Reproduction by tiny flagellated spores also occurs, but the formation of gametes remains to be proved. Representative genera are *Collozoum* (without a skeleton, colonial), *Thalassicolla* (without a skeleton), *Acanthometron* (with a skeleton). (Fig. 7.)

Class Sporozoa. A very large and heterogeneous assemblage of endoparasitic forms with hosts representing all animal phyla. Reproduction at some stage in the life history is by "spores," but these are not homologous throughout the class. In general, each species is limited to a specific host or to two hosts in each of which a part of the life history is spent. Transmission may be contaminative by resistant spores, or by inoculation of unprotected stages. Reproduction is usually by multiple fission (schizogony) followed by gamete formation and finally by sporulation (sporogony) to complete the life cycle. The alternation between the asexual and sexual phases is often associated with the change of hosts.

The class is sometimes divided into two subclasses, the Telosporidia and Neosporidia, with, in general, the following chief differences. In the former the production of spores terminates the life cycle, the sporozoites are vermicule in form, and the spores are without polar capsules; while in the latter, sporulation proceeds during the trophic phases of the life cycle, the sporozoites are amoeboid, and polar capsules are usually present in the spores. Though this division, suggested by Fritz Schaudinn in 1900, recognizes the natural assemblage of gregarines, coccidians and haemosporidians as Telosporidia, it fails to discriminate between the widely divergent forms included in the Neosporidia and, accordingly, it is customary to substitute for the latter group two subclasses: the Cnidosporidia with polar capsules, and the Acnidosporidia without such structures. But it is generally agreed that this is to some extent a temporary expedient awaiting further knowledge.

Subclass Telosporidia. The general characteristics are as stated above.

Order *Gregarinida.* A relatively homogeneous group of common parasites of invertebrates. For a brief period after the invasion of a host, development of the gregarine is intracellular, but most of the life history is extracellular with the parasites living in the intestine or various body cavities. Here the mature, worm-like forms (trophozoites) are either attached or move about by contortions of the body and by a characteristic gliding motion. Some gregarines are large enough to be readily visible to the naked eye. In general the body shows considerable differentiation and in some species is highly complex. In the cephaline type the body is divided into two parts (protomerite and deutomerite) by a transverse septum, and the protomerite itself may be capped by a special structure (epimerite) for attachment. The ectoplasm usually consists of several layers, including a region of myonemes which comprises both longitudinal and circular fibres, some of which may extend into the dense, granular endoplasm. Asexual reproduction by schizogony does not occur, the trophozoite proceeding directly to sexual phenomena and spore formation. The resistant spores usually pass from one host to another of the same species, but in some cases an alternate host is involved. Common examples of acephaline gregarines are the various species of *Monocystis* found in the seminal vesicles of earthworms. The more complex cephaline forms, chiefly inhabitants of the intestine of arthropods, are illustrated by members of the genus *Gregarina* that often parasitize meal beetles and cockroaches.

In addition to the eugregarines considered above, there is a small group of schizogregarines, so called because the life history includes a schizogonous cycle. The best known genera are *Ophryocystis* and *Schizocystis,* both with representative species that parasitize insects.

Order *Coccidia.* Intracellular parasites of many invertebrates and vertebrates, infesting chiefly the epithelial lining of the intestine and its derivatives, though some species invade the blood vascular system. The typical life history includes asexual multiplication by repeated schizogony followed by sexual phenomena and then sporogony involving the formation of resistant spores. Most members of the order are confined to a single host, but the

blood-dwelling haemogregarines alternate between the circulatory system and other organs of vertebrates and the intestine of invertebrates such as mites and leeches, and are without resistant spores. Representative coccidians are the various species of *Eimeria* that infest in particular mammals and birds, *Adelea ovata* living in centipedes, and *Haemogregarina stepanowi* alternating between turtles and leeches. *Isospora hominis* occurs rarely in man.

Order *Haemosporidia.* Intracellular coccidialike forms that typically undergo schizogony chiefly in the red blood cells and reticulo-endothelial tissue of vertebrates, and fertilization and sporogony in the digestive tract of blood-sucking arthropods, particularly insects. Resistant spores are not formed. The most important genus is *Plasmodium,* which comprises the malarial parasites of man carried by anopheline mosquitoes, as well as parasites of various lower vertebrates, including birds. Other representative genera are *Haemoproteus* and *Leucocytozoon,* transmitted especially to birds by biting flies. Differing somewhat from the typical haemosporidians are the piroplasms carried by ticks and often the cause of serious diseases in domestic mammals. Of especial interest is *Babesia* (*Piroplasma*) *bigemina,* the cause of Texas cattle fever. This was shown by the work of T. Smith and F. L. Kilborne in 1893, which was the first demonstration of the transmission of a protozoan parasite by an arthropod vector. Closely related to the various species of *Babesia* are members of the genus *Theileria,* such as *T. parva* that produces East Coast fever in African cattle. (Fig. 4.)

Subclass Cnidosporidia. An assemblage of species characterized by resistant spores with polar capsules. The products of the spores are amoeboid forms that start early in the life history to produce spores by internal budding. Accordingly an alternation of asexual and sexual cycles is absent, sexual phenomena occurring in the trophic stages. Species with intermediate hosts are unknown. (Fig. 15.)

Order *Myxosporidia.* Almost exclusively parasites of fishes, in which they sometimes cause severe epidemic disease. Some species develop as free forms in cavities, such as the gall and urinary bladders, while others are actual tissue parasites that produce more serious pathological effects. Common genera with many species, some infecting economically important fishes, are *Ceratomyxa, Myxidium* and *Myxobolus.*

Order *Actinomyxidia.* A small group of little-known species which inhabit the coelom and intestinal epithelium of aquatic annelids. The spores are usually triradiate and have three polar capsules. Representative genera are *Triactinomyxon* and *Hexactinomyxon.*

Order *Microsporidia.* Minute intracellular parasites that chiefly infest various tissues of arthropods and fishes. The best known species are *Nosema bombycis* of the silkworm moth and *N. apis* of bees, the former producing the pébrine disease of silkworms investigated by Louis Pasteur in 1865.

Subclass Acnidosporidia. A provisional group comprising little-known forms with simple spores lacking polar capsules.

Order *Sarcosporidia.* This order includes one important genus, *Sarcocystis,* with several species that infest the muscles of vertebrates, chiefly mammals, including mice, pigs, cattle and rarely man. The parasites form large "sarcocysts" in which crescentic spores are formed and produce a toxin that may prove fatal when injected into small mammals.

Order *Haplosporidia.* Largely an artificial assemblage of diverse forms, with affinities still to be determined, though certain species are probably closely related to the Microsporidia. They inhabit body cavities and tissues of invertebrates and lower vertebrates. Representative genera are *Haplosporidium,* present in aquatic annelids and mollusks, and *Ichthyosporidium* in fishes. A species of *Coelosporidium* occurs in cockroaches.

Class Ciliophora or Ciliata. An immense and clearly differentiated class, often called the Infusoria, characterized chiefly by the presence of cilia, and by two types of nuclei except in the subclass Protociliata. Division is typically transverse. Most species are monomorphic and are free-swimming in fresh and marine waters, though some are temporarily or permanently attached. Colony formation occurs.

Subclass Protociliata. A small subclass comprising the so-called opalinids which are endocommensals or parasites almost exclusively of frogs and toads. The body is uniformly coated with cilia but otherwise shows little similarity to other members of the class. The nuclei, from two to many in number, are not differentiated into micronuclei and macronuclei and there is no cytostome or contractile vacuole. Fertilization is by anisogamous gametes. Four genera are recognized: *Protoopalina, Zelleriella, Cepedea* and *Opalina.*

Subclass Euciliata. A very large subclass that includes all of the typical ciliates. Micronuclei and macronuclei are present and fertilization is by conjugation. Most species are free-living but some are commensals or parasites. The classification of this highly organized group of the Protozoa is based chiefly on the plan of distribution and the specialization of the cilia.

Order *Holotrichida.* The holotrichs are usually provided with unspecialized cilia, either over the entire surface or restricted to certain regions of the body. The best known genus is *Paramecium,* represented by about ten clearly-defined species, some of which are among the most widely studied animals. Among other common genera are *Chilodonella, Colpoda, Colpidium, Spathidium* and *Didinium.* Most holotrichs are free-living, but many are commensal or endoparasitic, including a unique group of astomatous species. *Ichthyopthirius multifilius* is an ectoparasite of fresh-water fishes which sometimes causes serious epidemics in aquaria. (Figs. 1, 11.)

Order *Spirotrichida.* Species with a complex adoral zone of cilia united to form membranelles, and usually an undulating membrane, in addition to other ciliation. Included are the *heterotrichous* forms with relatively short cilia over the rest of the body, represented, for example, by the various species of *Stentor, Spirostomum, Blepharisma, Bursaria* and *Balantidium;* the *oligotrichous* forms with general body ciliation reduced or wanting, as in the genera *Halteria, Tintinnidium,* and *Epidinium;* and finally the *hypotrichous* forms with markedly flattened bodies provided with cirri on the ventral surface for creeping, etc., including such common genera as *Oxytricha, Stylonychia* and *Euplotes.*

Order *Peritrichida.* Members of this order are typically bell-shaped and attached by a stalk, and accordingly are commonly called bell animalcules. Ciliation is practically restricted to the rim of the bell and peristome, and includes an adoral zone. Representatives are the many species of *Vorticella* and the closely related colonial genera *Epistylis, Zoothamnium* and *Carchesium.*

Order *Chonotrichida.* A very small group of ciliates superficially similar but clearly unrelated to the peritrichs. All live attached to aquatic arthropods. The common genus is *Spirochona.*

Subclass Suctoria. A unique but widely distributed group of fresh-water and marine species in which the cilia are confined to the young, free-swimming stages which arise as buds. The adults are typically sessile and are provided with tentacles by means of which they adhere to the prey and withdraw its contents. Many species live attached to the surface of aquatic organisms, usually as commensals but sometimes as parasites, while others are highly modified endoparasites. Some species infest *Paramecium* and other ciliates. Common genera are *Tokophrya, Acineta* and *Ephelota.* (Fig. 10.)

Bibliography.—Standard treatises affording a survey of the Protozoa and an introduction to the immense literature in the field of protozoology include: Otto Buetschli, "Protozoen," in Bronn's *Klassen und Ordnungen des Tier-Reichs,* 3 vols. (Leipzig, 1880–89); C. M. Wenyon, *Protozoology* (London and New York, 1926); F. J. Cole, *History of Protozoology* (London, 1926); F. Doflein and E. Reichenow, *Lehrbuch der Protozoenkunde,* 5th Auflage (Jena, 1927–28); G. N. Calkins; *Biology of the Protozoa,* 2nd ed. (1933); A. Kahl, "Ciliata," in *Die Tierwelt Deutschlands* (Jena, 1935); R. R. Kudo, *Protozoology,* 3rd ed. (1946); L. H. Hyman, *The Invertebrates: Protozoa through Ctenophora* (1940); G. N. Calkins and F. M. Summers (editors), *Protozoa in Biological Research* (1941).

(L. L. W.)

PROUD, JOSEPH (1745–1826), English clergyman, was born in Beaconsfield, Buckinghamshire on March 22, 1745. He served as minister of the general baptist congregation at Knipton,

Leicestershire beginning about 1772, and in 1775 accepted a similar position at Fleet, Lincolnshire, where he was ordained in 1780. In 1791 he was ordained minister in the "new church" and opened the Birmingham "temple" in the same year. He continued to preach in various churches in Manchester and London where his oratory attracted large audiences. He wrote nearly 300 hymns and published numerous books, some of which went through several editions. He died at Handsworth, near Birmingham on Aug. 3, 1826.

PROUD, ROBERT (1728–1813), U.S. educator and historian, was born near Yarm, Yorkshire on May 10, 1728. After attending a Friends' school he went to London in 1750 and continued his studies under the guidance of Dr. Fothergill. In 1759 he came to the United States and opened a boys' school in Philadelphia. In 1761 he became master of a Friends' school, a position he held until 1770, and later, from 1780 to 1790. His important work, *The History of Pennsylvania* (2 vols., 1797–98), contained much valuable material on the early history of the area. Proud died at Philadelphia on July 5, 1813.

PROUDHON, PIERRE JOSEPH (1809–1865), French socialist and political writer, was born on Jan. 15, 1809, at Besançon. He came of poor parents, and was mainly self-educated. At 19 he became a working compositor; and later, as a proofreader, he acquired a competent knowledge of theology and Hebrew, which he compared with Greek, Latin and French. On the strength of the knowledge acquired in this way he wrote an *Essai de grammaire générale*. In 1838 he obtained the *pension Suard*, a bursary of 1,500 francs a year for three years, for the encouragement of young men of promise, which was in the gift of the academy of Besançon.

In 1839 he wrote a treatise *L'Utilité de la célébration du dimanche* which contained the germs of his revolutionary ideas, and in the following year, after a short sojourn in Paris, he published *Qu'est-ce que la propriété?* His famous answer, "La propriété, c'est le vol" (property is theft), displeased the academy of Besançon, and there was some talk of withdrawing his *pension;* but he held it for the regular period. Proudhon's theory of property as the right of *aubaine* is substantially the same as the theory of capital held by Marx and most of the later socialists. Marx, however, always greatly detested Proudhon and his doctrines, and attacked him violently in his *Misère de la philosophie*. Property and capital are defined and treated by Proudhon as the power of exploiting the labour of other men, of claiming the results of labour without giving an equivalent. Proudhon's famous paradox, "La propriété, c'est le vol," is merely a trenchant expression of this general principle. As slavery is assassination inasmuch as it destroys all that is valuable and desirable in human personality, so property is theft inasmuch as it appropriates the value produced by the labour of others without rendering an equivalent. For property Proudhon would substitute individual possession, the right of occupation being equal for all men. For his third memoir on property, which took the shape of a letter to the Fourierist, Considérant, he was tried at Besançon but was acquitted. In 1846 he published his greatest work, the *Système des contradictions économiques ou philosophie de la misère*. In 1847 he settled in Paris, and in the following year gained notoriety during the revolution. He was the moving spirit of the *Représentant du peuple* and other journals of advanced views, and as member of assembly for the Seine department he proposed an impost of one-third on interest and rent, which was rejected. His attempt to found a bank which should operate by granting gratuitous credit was also a complete failure. For his violent speeches, Proudhon suffered three years of imprisonment at Paris. As Proudhon aimed at economic rather than political innovation, he accepted the second empire, and lived in comparative quiet until the publication of his work, *De la Justice dans la révolution et dans l'eglise* (1858), in which he attacked the church and other existing institutions. To escape imprisonment he fled to Brussels, returning later to France in broken health. He died at Passy on Jan. 16, 1865.

Personally Proudhon was one of the most remarkable figures of modern France. His life was marked by the severest simplicity; he was affectionate in his domestic relations, a loyal friend, and strictly upright in conduct. He opposed the prevailing French socialism; and, though an enemy of the dominant ideas and institutions, he was free from feelings of personal hate. In all that he said and did he was the son of the people, who had not been broken to the usual social and academic discipline; hence his roughness, his one-sidedness, and his exaggerations; but he is always vigorous, and often brilliant and original.

Although in his own words "the great part of his publications formed only a work of dissection and ventilation, so to speak, by means of which he slowly makes his way towards a superior conception of political and economic laws," yet the groundwork of his teaching is clear. He believed in the absolute truth of a few moral ideas, with which it was his aim to mould and suffuse political economy. Of these fundamental ideas, justice, liberty and equality were the chief. What he desiderated, for instance, in an ideal society was perfect equality of remuneration on the principle that the duration of labour is the just measure of value. He pursued this theory to its logical conclusion, but looked forward to a period in human development when the present inequality in the capacity of men would be reduced to an inappreciable minimum. From the principle of service as the equivalent of service is derived his axiom that property is the right of *aubaine, i.e.,* the right in virtue of which the sovereign, from the earliest monarchy, claimed the goods of an unnaturalized stranger who had died in his territory. Property is a right of the same nature, with a like power of appropriation in the form of rent, interest, etc. Proudhon's aim was to realize a science of society resting on principles of justice, liberty and equality thus understood; "a science absolute, rigorous, based on the nature of man and of his faculties, and on their mutual relations, a science which we have not to invent, but to discover." But he saw that such ideas could only be realized through a long process of social transformation. He attacked the schools of Saint-Simon and Fourier for thinking that society could be changed off-hand by a ready-made and complete scheme of reform.

In social change Proudhon distinguishes between the transition and the perfection of achievement. With regard to the transition he advocated the progressive abolition of the right of *aubaine,* by reducing interest, rent, etc., but he had no clear conception of the goal. The organization he desired was one on collective principles, a free association which would take account of the division of labour, and which would maintain the personality both of the man and the citizen. Connected with this was his famous paradox of *anarchy,* as the goal of the free development of society, by which he meant that through the ethical progress of men government should become unnecessary. "Government of man by man in every form," he says, "is oppression. The highest perfection of society is found in the union of order and *anarchy.*" Proudhon, indeed, was the first to use the word *anarchy,* not in its revolutionary sense, but to express the highest perfection of social organization.

A complete edition of Proudhon's works, including his posthumous writings, was published at Paris (1875). *See* also *P. J Proudhon, sa vie et sa correspondance,* by Sainte-Beuve (1875); Beauchéry, *Économie sociale de P. J. Proudhon* (Lille, 1867); Spoll, *P. J. Proudhon, étude biographique* (1867); Marchegay, *Silhouette de Proudhon* (1868); Putlitz, *P. J. Proudhon, sein Leben und seine positiven Ideen* (1881); Diehl, *P. J. J. Proudhon* (Stuttgart, 1899).

PROUST, JOSEPH LOUIS (1754–1826), French chemist, was born on Sept. 26, 1754, at Angers, where his father was an apothecary. After beginning the study of chemistry in his father's shop he came to Paris and became apothecary in chief to the Salpetrière, also lecturing on chemistry at the *musée* of the aeronaut J. F. Pilâtre de Rozier, whom he accompanied in a balloon ascent in 1784. Next, he went to Spain, where he taught chemistry first at the artillery school of Segovia, and then at Salamanca, finally becoming in 1789 director of the royal laboratory at Madrid. In 1808 he lost both his position and his money by the fall of his patron (Charles IV), and retired first to Craon in Mayenne and then to Angers, where he died on July 5, 1826.

Proust's great contribution to chemistry was his establishment of the fundamental principle of the constant composition of many compounds. On this subject he maintained a long controversy with C. L. Berthollet, who was led by his doctrine of mass-action to deny that substances always combine in constant and definite proportions. Proust, on the other hand, maintained that compounds always contain definite quantities of their constituent elements, and that in cases where two or more elements unite to form more than one compound, the proportions in which they are present vary *per saltum*, not gradually. In 1799 he proved that copper carbonate, whether natural or artificial, always has the same composition, and later he showed that the two oxides of tin and the two sulphides of iron always contain the same relative weights of their components and that no intermediate indeterminate compounds exist. His analytical skill enabled him to demonstrate the inaccuracy of the researches by which Berthollet attempted to support the opposite view, and to show among other things that some of the compounds which Berthollet treated as oxides were in reality hydrates containing chemically combined water, and the upshot was that by 1808 he had fully vindicated his position. Proust also investigated the varieties of sugar that occur in sweet vegetable juices, distinguishing three kinds, and he showed that the sugar in grapes, of which he announced the existence to his classes at Madrid in 1799, is identical with that obtained from honey by the Russian chemist J. T. Lowitz (1757–1804).

Besides papers in scientific periodicals he published *Indagaciones sobre el estañada de cobre, la vajilla de estaño y el vidriado* (1803); *Mémoire sur le sucre de raisins* (1808); *Recueil des mémoires relatifs á la poudre à canon* (1815); and *Essai sur une des causes qui peuvent amener la formation du calcul* (1824).

PROUST, MARCEL (1871–1922), French man of letters, was born in Paris on July 10, 1871. His father was a professor of medicine, and his mother was of Jewish extraction. He was educated at the lycée Condorcet, and about 1892 he was for some time associated with Léon Blum, Louis Mirhlfeld and Tristan Bernard on the *Revue Blanche*, a periodical conducted by a select group of intellectuals, mostly Jewish. Becoming a favourite in the salons—especially those of Mme. de Caillavet and Madeleine Lemaire—he wrote a number of society love-stories (collected in 1896 under the title *Les plaisirs et les jours*) distinguished by their psychological subtlety. He also attained reputation as a clever writer of *pastiches*. He became an enthusiastic admirer of John Ruskin and translated several of his works into French, including the *Bible of Amiens*, to which he contributed a valuable preface.

In 1902 Proust's health began to fail. Thenceforward he was reluctantly obliged to lead an extremely retired and careful life, and for many years it looked as if he had altogether abandoned literature, in which his name hitherto had not been known outside a small circle of friends. He was reading and writing a great deal, however. The interminable discursiveness of Ruskin, which French readers do not suffer gladly, was to him a constant source of delight, and Saint-Simon, ever one of his favourite authors, exerted a powerful influence upon him at this time. Thus it came about that, having unlimited time at his disposal, he embarked upon a long and leisurely work, full of minute detail, in which was imprisoned, as in a net, his whole experience of life; in which the *salon* life he loved was revived in all its details and observances like the court life in Saint-Simon's memoirs; in which the people he had known provided the materials for new, fuller and richer characters (M. de Charlus, for example, is a blending of three different people of Proust's acquaintance), and in which the author sought out and lived the past over again. Hence the general title given to the 15 volumes of the series, *A la recherche du temps perdu* (1913, etc.).

This lengthy work had almost been completed when Proust published the first part, *Du côté de chez Swann*, in 1913. The freshness and minuteness of the recollections of childhood attracted some attention, but none the less Proust, who had had to publish the first part at his own expense, had difficulty in finding a publisher for the second, *L'ombre des jeunes filles en fleurs*. When it did appear its qualities were at once appreciated by Léon Daudet, whose enthusiastic articles, followed by the award of the Prix Goncourt in 1918, brought Proust's name prominently before the public, and he was read, discussed and criticised everywhere. Two more parts appeared during Proust's lifetime—*Le côté de Guermantes* and *Sodome et Gomorrhe*, both in 1921. When he died in Paris, Nov. 18, 1922, he left three parts still in manuscript—*La prisonnière*, published in 1924, *Albertine Disparue* (1926) and *Le temps retrouvé* (1926).

Proust's influence, especially since his death, has been considerable. He introduced into the novel an analytic method which has a superficial resemblance to that of Meredith, but is more properly comparable with that of Freud. That the name and notion of time should appear in the general title of his great work is not without significance. By a curious coincidence he was related by marriage to Bergson, the philosopher of "creative time," and the term "creative time" aptly describes the psychological time which Proust explores, seeks and recovers. His people are never given as "characters" in the fashion of La Bruyère or Balzac; they are always in process of development, change and continual creation.

Part of Proust's success was due to the very thing that is likely to tell against his lasting reputation, viz.: the fact that his characters, beginning with the "I" of the book, are exceptional, an erotic and mysterious group having little in common with the generality of mankind. This is true not only of *Sodome et Gomorrhe* and Proust's emphasis upon homosexuality, but also of the idle life and ultimate nothingness of the people of his world, their lack of all interests other than those of social life, and the indifference that the ordinary reader must always feel as to their fate. On the other hand, there will be a taste for Proust so long as there is a taste for psychology as an end in itself, and so long as the play of memory, the searching and brooding that pertain to the conquest of the past, afford to some men a sufficient reason for living or a romantic manner of not living. The following translations by C. K. Scott Moncrieff appeared in English: *Swann's Way* (1922); *Within a Budding Grove* (1924); *The Guermantes Way* (1925); *Cities of the Plain* (trans. of *Sodome et Gomorrhe*) (2 vols. 1927); *The Captive* (1929). (A. T.)

Pierre-Quint, *Marcel Proust, sa vie, son oeuvre* (1925, Eng. trs. 1927); Benoist-Méchin, *La Musique et l'immortalité dans l'oeuvre de Marcel Proust* (1926); R. Dreyfus, *Marcel Proust à dix-sept ans* (1926), and *Souvenirs sur Marcel Proust* (1926); G. Gabory, *Essai sur Marcel Proust* (1926); *Marcel Proust*, by various writers, with bibliography (1926); P. Souday, *Marcel Proust* (1927); R. Fernandez, *Les Cahiers de Marcel Proust* (1927); and Clive Bell, *Proust* (1928). His *Lettres inédites* were published with a preface by Camille Vettard in 1926. *Chroniques*, a selection of his articles chiefly from *Le Figaro*, was edited by R. Proust (1927).

PROUSTITE, a mineral consisting of silver sulpharsenite, Ag_3AsS_3, known also as light red silver ore, and an important source of the metal. It is closely allied to the corresponding sulphantimonite, pyrargyrite, from which it was distinguished by the chemical analyses of J. L. Proust in 1804, after whom the mineral received its name. Many of the characters being so similar to those of pyrargyrite (*q.v.*) they are mentioned under that species. The colour is scarlet-vermilion and the lustre adamantine; crystals are transparent and very brilliant, but on exposure to light they soon become dull black and opaque. The streak is scarlet, the hardness 2·5, and the specific gravity 5·57. The mode of occurrence is the same as that of pyrargyrite, and the two minerals are sometimes found together. Magnificent groups of large crystals have been found at Chañarcillo in Chile; other localities which have yielded fine specimens are Freiberg and Marienberg in Saxony.

PROUT, SAMUEL (1783–1852), English water-colour painter, was born at Plymouth on Sept. 17, 1783. He spent whole summer days, in company with the ill-fated Haydon, in drawing the quiet cottages, rustic bridges and romantic water-mills of Devon. He made a journey through the Cornwall countryside for the purpose of furnishing sketches for Britton's *Beauties of Eng-*

land. After his removal in 1803 to London, which became his headquarters after 1812, a new scene of activity opened up before Prout. He now endeavoured to correct and improve his style by the study of the works of the rising school of landscape painters. To earn a living he painted marine pieces for Palser the printseller, received pupils and published many drawing books for art students. He was likewise one of the first who turned to account in his profession the newly-invented art of lithography. It was not however, until about 1818, when he visited the Continent and first saw the quaint streets and market-places of continental cities, that Prout discovered his proper sphere. All his faculties sprang into unwonted activity. His eye readily caught the picturesque features of the architecture, and his hand recorded them in drawings which were admirable in line, composition and colour. At the time of his death, on Feb. 10, 1852, there was scarcely a nook in France, Germany, Italy and the Netherlands which his quiet, benevolent, observant eye had not searched for antique gables and sculptured pieces of stone. In Venice especially there was hardly a pillar which his eye had not lovingly studied and his pencil had not dexterously copied.

See a memoir of Prout, by John Ruskin, in *Art Journal* for 1849, and the same author's *Notes on the Fine Art Society's Loan Collection of Drawings by Samuel Prout and William Hunt* (1879–80); *see* also the "Winter Number" of the *Studio* (1914–15), for reproductions of his sketches.

PROUT, WILLIAM (1785–1850), English chemist and physician, was born at Horton, Gloucestershire, on Jan. 15, 1785, and died in London on April 9, 1850. His life was spent as a practising physician in London, but he also occupied himself with chemical research. He was an active worker in physiological chemistry, and found in 1823 that the acid contents of the stomach contain hydrochloric acid which is separable by distillation. In 1815 he published anonymously in the *Annals of Philosophy* a paper in which he calculated that the atomic weights of a number of the elements are multiples of that of hydrogen; and in a second paper published in the same periodical the following year he suggested that the *πρώτη ὕλη* of the ancients is realized in hydrogen, from which the other elements are formed by some process of condensation or grouping. This view, generally known as "Prout's hypothesis," at least had the merit of stimulating inquiry, and many of the careful determinations of atomic weights undertaken since its promulgation have been provoked by the desire to test its validity. It is also particularly interesting in view of recent developments in the study of atomic structure (*see* Atom).

PROUTY, CHARLES AZRO (1853–1921), U.S. lawyer, was born in Newport, Vt. on Oct. 9, 1853. He graduated at Dartmouth college in 1875 and subsequently became principal of Newport academy. He was admitted to the bar in 1882 and practised law in Newport until 1896. In 1888 he was a member of the Vermont house of representatives and from 1888 to 1896 served as a reporter of decisions of the state supreme court. He was appointed to the U.S. Interstate Commerce commission in 1896, holding office until 1914 and serving as chairman in 1912–13. In 1914 he was made director of valuation for the commission and from 1918 to 1920 was director of public service and accounting in the U.S. Railroad administration. He died at Newport on July 8, 1921.

PROVENÇAL LANGUAGE AND LITERATURE. The term Provençal is employed in two different meanings. (1) *Lato sensu,* it embraces all idioms of Latin origin spoken in Southern France over a zone extending south of a line which starts at the mouth of the Gironde, passes through Bordeaux, Libourne, Mussidan, Péngueux, Nontron, Mouhet, Bellac, Limoges, Guéret, Chénérailles, Montluçon, Verneuil, Clermont-Ferrand, Saint-Bonnet-le-Château, Saint Sauveur-en-Rue, Gilhoc, Saint-Vallier, Romans, Die, Montmaur and finishes at Puy-Saint André. (2) *Stricto sensu,* it is applied to the idioms spoken in the Alpes-Maritimes, Basses-Alpes, Var and Bouches-du-Rhône departments. It was long customary to distinguish the dialects of Southern France by the names of the old provinces in which they occur, viz., Béarnais, Languedocien, Rouergat, etc. The classification now generally adopted is: (1) Gascon, (2) Provençal moyen and Provençal alpin (from Agen to Mentone), (3) Auvergnat and Limousin, (4) Catalan (*q.v.*).

With the 12th century arose a literary language used as a *κοινή* by the Troubadors. As some of the most celebrated of these poets, Bernard de Ventadour, Arnaud Daniel, Bertrand de Born and Jaucelm Faidit came from the Limousin, this *κοινή* was long known as *lengua lemosina;* a name, however, not to be misinterpreted. The literary language was not homogeneous, but composite.

The Troubadors conveyed this form of Provençal with them to Northern France, Italy, Spain and Portugal. When Languedoc passed to the House of France (1272) two languages, Latin almost exclusively and French to a very limited degree, were employed for administrative purposes. Minute examination of the documents contained in the archives of Southern France has recently proved that French exerted only inappreciable influence upon Provençal down to the close of mediaeval times. The Frenchification was not the outcome of a long, slow process. Indeed at the end of the Hundred Years' War, Provençal was still highly vigorous both in administrative and general use; it was then, from 1450 to 1600, very rapidly penetrated by French. First to yield was Northern Limousin; it was followed next by Périgord, Bordelais, Agenais, then Gascony, and finally by the Pyrenees which resisted until the last years of the 18th century. The initial period of this penetration may be placed about 1540 (*see* A. Brun, *Recherches historiques sur l'introduction du français dans les provinces du midi,* 1923). The various patois, continuing to be spoken by the middle class and peasantry developed freely. The new lease of life upon which the Southern idioms entered during the second half of the 19th century, must not be regarded as an unexpected accident. It had been prepared by the reawakening sense of nationality and promoted by the efforts of scholars, historians and men of letters, all of whom united in lauding the qualities of the ancient tongue and urging the Southerners to voice their native feelings and aspirations in their native "language." Among the leading representatives of the movement must be mentioned F. Mistral, not only on account of his literary masterpieces, especially his immortal *Mirèio* (1859), but also for his publication of *Lou Tresor d'ou Felibrige* (1878–86), the Provençal French dictionary which conferred *lettres de noblesse* on the new classical language of Provence, sprung from divers patois of the Bouches-du-Rhône. Provençal (including Catalan) is spoken by about 10,000,000 persons in France.

The Provençal dialects are less divergent from Latin than is the case with French. The following particulars will help to make clear what has been called "the archaic character" of Provençal and give, at the same time, a concise view of its special phonetic features.

I. Vowels

(*a*) Latin tonic free vowels: L. *amare,* Pr. *amar* (later *ama*), F. *amer* (later *aimer*). L. *pedem,* Pr. *pe,* F. *pie* (later spelt *pied*). L. *credere,* Pr. *crezer* (later *crese* in some parts), Bearnais *creder* (later *crede*); F. *croire* (later *croire*); L. *solum,* Pr. *sol,* Fr. *sueil* (later *seul*); L. *florem,* Pr. *flor,* F. *flour* (later *fleur*).

(*b*) Latin tonic free diphthong *au:* L. *aurum,* Pr. *aur,* F. *or.*

(*c*) Posttonic *a:* L. *clara,* Pr. *clara* (later *claro*), F. *clere* (later *claire*).

(*d*) Latin intertonic free *a:* L. *duramente,* Pr. *duramen,* F. *durement.*

II. Consonants

(*e*) Latin *C* and *G* before *A* were kept *C* and *G* in Provençal (except Limousin and Auvergne) and became *CH* (first pronounced TCH) and *J* (first pronounced DJ) in French (except Normanno-Picard dialect where they persisted as C and G, like Provençal): L. *caballum,* Pr. *Caval,* F. *cheval;* L. *gallina,* Pr. *Galina* (later *Galino*), F. *Geline.*

(*f*) Latin intervocalic *C:* L. *pacare,* Pr. *pagar* (later *paga*), F. *pager;* L. *securum,* Pr. *segur* (in part of Basses-Pyrénées

secur). Latin intervocalic *G:* L. *plaga*, Pr. *plaga* (later *plago*), F. *plaie;* L. *ruga*, Pr. *ruga* (later *rugo*), F. *rue*. Latin intervocalic *T:* L. *vita*, Pr. *vida* (later *vido*), F. *vie;* L. *quaternum*, Pr. *cazern*, F. *cahier*. Latin intervocalic *D:* L. *credere*, Pr. *crezer* (in part of Basses-Pyrénées *creder*), F. *croire* (later *croire*).

N.B. In some parts of Mod. Pr. there is a form *creire* which represents the state of evolution to be found in France until the 13th century. Latin intervocalic *DR, TR:* L. *quadratum*, Pr. *carat*, F. *carré*, L. *patrem*, Pr. *patre*, F. *père* (later *père*).

(*g*) In the group *S*+1 or 2 consonants, *s* has been kept in Provençal spelling and pronunciation; from French pronunciation it disappeared after the 13th century, although it was preserved in spelling until the middle of the 18th century (suppressed in the 3rd edition of the *Dictionnaire de l'Académie Française*, 1740); L. *scribere*, Pr. *escriure*, F. *escrire* (later *écrire*); L. *castellum*, Pr. *castel*, F. *chasteau* (later *château*).

(*h*) Among the final consonants let us quote *p, v, s,* Vulg. L. *capum* (cl L. *caput*), Pr. *cap* (a regression of *cat*—a form which is not attested in the documents at our disposal), F. *chief*; L. *brevem*, Pr. *brèu*, F. *bref*. Final *s* has been preserved both in spelling and pronunciation in the greatest part of Provençal; it disappeared from the pronunciation of French in the course of the 13th century. L. *causas*, Pr. *cauzas* (later *cauzos*), F. *choses*.

Among the Provençal dialects Gascon has quite peculiar features, the following three are most specially characteristic: (*a*) Change of Latin intervocalic *ll* to *r;* L. *appellare*, Gasc. *aperar* (later *apera*); (*b*) change of Latin final *ll* to *t:* L. *agenellum*, Gasc. *agnet;* (*c*) change of Latin *f* to aspirate *h:* L. *femina*, Gasc. *femna* till the end of the 13th century, then *hemna* (later *henno*).

Note that there are two other peculiar features (*d*) the pronunciation of *b* as in Spanish (*i.e.*, an intermediary sound between *b* and *v*); (*e*) the fall of Latin intervocalic *n* as in Portuguese: L. *gallina*, Gasc. *garia* (later *gario*). But (*d*) has gone beyond Gascony since the middle ages, and (*e*) is not to be found in Bordelais.

As general remarks on the morphology it may be pointed out that the declension of nouns and adjectives ceased to exist earlier than in French: the 13th century is the limit reached by the distinction between the two cases. In some parts like Béarn no trace of any declension at any time is to be found. In the conjugation we find (*a*) a past simple ending in—*ei* (like *cantei, cantest, cantet, cantem, cantetz, canteron; vendei, vendest*, etc.), most likely corresponding to L.—*ĕdi*—*ĕti*, as in *dedi steti*. (*e*) a remnant of Latin pluperfect ending in *aram* (contracted from *averam*), *iram* (contracted from *iveram*), *ederam*, e.g., *cantara* or *cantera, partira, vendera* used in the meaning of a conditional. There is a great similarity in the aspect of old and modern Provençal. The only important facts since the 15th century are (*a*) the change of final *a* into *o* (except in some parts where it has persisted as *a*, and in others where it became *e*, closer than in French).

(*i*) The great simplification of the conjugations, many verbs having passed to the—*ar* conjugation. (L. B.)

LITERATURE

Provençal literature is much more easily defined than the language in which it is expressed. Starting in the 11th and 12th centuries in several centres it thence gradually spread out, first over the greater portion, though not the whole of southern France, and then into the north of Italy and Spain. It never felt the influence of the neighbouring literatures. At the time of its highest development (12th century) the art of composing in the vulgar tongue did not exist, or was only beginning to exist, to the south of the Alps and the Pyrenees. In the north, in the country of French speech, vernacular poetry was in full bloom; but between the districts in which it had developed—Champagne, Ile de France, Picardy and Normandy—and the region in which Provençal literature had sprung up, there seems to have been an intermediate zone formed by Burgundy, Bourbonnais, Berry, Touraine and Anjou which, far on in the middle ages, appears to have remained almost barren of vernacular literature. In its rise Provençal literature stands completely by itself, and in its development it long continued to be absolutely original. It presents at several points genuine analogies with the sister-literature of northern France; but these analogies are due principally to certain primary elements common to both and only in a slight degree to mutual reaction.

It must be inquired, however, what amount of originality could belong to any, even the most original, Romanic literature in the middle ages. In all Romanic countries compositions in the vernacular began to appear while the custom of writing in Latin was still preserved by uninterrupted tradition. Even during the most barbarous periods, when intellectual life was at its lowest, it was in Latin that sermons, lives of saints more or less apocryphal, accounts of miracles designed to attract pilgrims to certain shines, monastic annals, legal documents, and contracts of all kinds were composed. When learning began to revive, as was the case in northern and central France under the influence of Charlemagne and later in the 11th century, it was Latin literature which naturally received increased attention, and the Latin language was more than ever employed in writing. Slowly and gradually the Romanic languages, especially those of France, came to occupy part of the ground formerly occupied by Latin, but even after the middle ages had passed away the parent tongue retained no small portions of its original empire. Consequently Romanic literatures in general (and this is especially true of Provençal, as it does not extend beyond the mediaeval period) afford only an incomplete representation of the intellectual development of each country. Those literatures even which are most truly national, as having been subjected to no external influence, are only to a limited extent capable of teaching us what the nation was. They were, in short, created in the interests of the illiterate part of the people, and to a considerable degree by men themselves almost devoid of literary learning. But that does not make them less interesting.

Origin.—It took poetic form; and its oldest monuments show a relative perfection and a variety from which it may be concluded that poetry had already received a considerable development. The oldest poetic text, of which the date and origin are not surely determined, is said to be a Provençal burden (Fr. *refrain*) attached to a Latin poem which has been published (*Zeitschrift fur deutsche Philologie*, 1881, p. 335) from a Vatican MS., written, it is asserted, in the 10th century. But it is useless to linger over these few words, the text of which seems corrupt, or at least has not yet been satisfactorily interpreted. The honour of being the oldest literary monument of the Provençal language must be assigned to a fragment of 257 decasyllabic verses preserved in an Orleans ms. and frequently edited and annotated since it was first printed by Raynouard in 1817 in his *Choix des poésies originales des troubadours*. The poem is consequently a didactic piece composed by a "clerk" knowing Latin. He doubtless preferred the poetic form to prose because his illiterate contemporaries were accustomed to poetry in the vulgar tongue, and because this form was better adapted to recitation; and thus his work, while a product of erudition in as far as it was an adaptation of a Latin treatise, shows that at the time when it was composed a vernacular poetry was in existence. The writing of the ms. is of the first half of the 11th century. The peculiarities of the language point to the north of the Provençal region, probably Limousin or Marche. It is the beginning of a poem in which the unknown author, taking Boethius's treatise *De consolatione philosophiae* as the groundwork of his composition, adopts and develops its ideas and gives them a Christian colouring of which there is no trace in the original. Thus from some verses in which Boethius contrasts his happy youth with his afflicted old age he draws a lengthy homily on the necessity of laying up from early years a treasure of good works. A little later, at the close of the same century, we have the poems of William IX, count of Poitiers, duke of Guienne. They consist of 11 very diverse strophic pieces, and were meant to be sung. Several are love songs; one relates a *bonne fortune* in very gross terms; and the most important of all—the only one which can

be approximately dated, being composed at the time when William was setting out for Spain to fight the Saracens (about 1119) —expresses in touching and often noble words the writer's regret for the frivolity of his past life and the apprehensions which oppressed him as he bade farewell, perhaps forever, to his country and his young son. We also know from Ordericus Vitalis that William IX had composed various poems on the incidents of his ill-fated expedition to the Holy Land in 1101. And it must further be mentioned that in one of his pieces (*Ben voil que sapchon li plusor*) he makes a very clear allusion to a kind of poetry which we know only by the specimens of later date, the *partimen,* or, as it is called in France, the *jeu parti.* William IX was born in 1071 and died in 1127. There is no doubt that the most prolific period of his literary activity was his youth. On the other hand there is no reason to believe that he created the type of poetry of which he is to us the oldest representative. It is easy to understand how his high social rank saved some of his productions from oblivion while the poems of his predecessors and contemporaries disappeared with the generations who heard and sang them. The contrast in form and subject between the Boethius poem and the stanzas of William IX is an indication that by the 11th century Provençal poetry was being rapidly developed in various directions. Whence came this poetry? How and by whose work was it formed? That it has no connection whatever with Latin poetry is generally admitted. The view which seems to meet with general acceptance, though it has not been distinctly formulated by any one, is that Romanic poetry sprang out of a popular poetry quietly holding its place from the Roman times, no specimen of which has survived—just as the Romanic languages are only continuations with local modifications of Vulgar Latin. There are both truth and error in this opinion. Romanic versification, as it appears in the Boethius poem and the verses of William IX, and a little farther north in the poem of the *Passion* and the *Life of St. Leger* (10th or 11th century), has with all its variety some general and permanent characteristics; it is rhymed, and it is composed of a definite number of syllables certain of which have the syllabic accent. This form has evident affinity with the rhythmic Latin versification, of which specimens exist from the close of the Roman empire in ecclesiastical poetry. The exact type of Romanic verse is not found in this ecclesiastical Latin poetry; the latter was not popular. However, it may be assumed that there was a popular rhythmic poetry from which Romanic verse is derived.

Again, as regards the substance, the poetic material, we find nothing in the earliest Provençal which is strictly popular. The extremely personal compositions of William IX have nothing in common with folklore. They are subjective poetry addressed to a very limited and probably rather aristocratic audience. The same may be said of the Boethius poem, though it belongs to the quite different species of edifying literature; at any rate it is not popular poetry. Vernacular compositions seem to have been at first produced for the amusement, or in the case of religious poetry, for the edification, of that part of lay society which had leisure and lands, and reckoned intellectual pastime among the good things of life. Gradually this class, intelligent, but with no Latin education, enlarged the circle of its ideas. In the 12th century, and still more in the 13th, historical works and popular treatises on contemporary science were composed for its use in the only language it understood; and vernacular literature continued gradually to develop partly on original lines and partly by borrowing from the literature of the "clerks." But in the 11th century vernacular poetry was still rather limited, and had hardly any higher object than the amusement or the edification of the upper classes. An aristocratic poetry, such as it appears in the oldest Provençal compositions, cannot be the production of shepherds and husbandmen; and there is no probability that it was invented or even very notably improved by William IX.

From what class of persons then did it proceed? Latin chroniclers of the middle ages mention as *ioculares, ioculatores,* men of a class not very highly esteemed whose profession consisted in amusing their audience either by what we still call jugglers' tricks, by exhibiting performing animals, or by recitation and song. They are called *joglars* in Provençal, *jonglers* or *jongleurs* in French; and they were the first authors of poetry in the vernacular both in the south and in the north of France. To the upper classes who welcomed them to their castles they supplied that sort of entertainment now sought at the theatre or in books of light literature. There were certain of them who, leaving buffoonery to the ruder and less intelligent members of the profession, devoted themselves to the composition of pieces intended for singing, and consequently in verse. In the north, where manners were not so refined and where the taste for warlike adventure prevailed, the jongleurs produced *chansons de geste* full of tales of battle and combat. In the courts of the southern nobles, where wealth was more abundant and a life of ease and pleasure was consequently indulged in, they produced love songs. There is probably a large amount of truth in the remark made by Dante in Ch. XXV of his *Vita nuova,* that the first to compose in the vulgar tongue did so because he wished to be understood by a lady who would have found it difficult to follow Latin verses. And in fact there are love songs among the pieces by William of Poetiers; and the same type preponderates among the compositions of the troubadours who came immediately after him. But it is worthy of note that in all this vast body of love poetry there is no epithalamium nor any address to a marriageable lady. The social conditions of the south of France in the feudal period explain in great measure the powerful development of this kind of poetry, and also its peculiar characteristics—the profound respect, the extreme deference of the poet towards the lady whom he addresses. Rich heiresses were married young, often when hardly out of their girlhood, and most frequently without their fancy being consulted. But they seem after marriage to have enjoyed great liberty. Eager for pleasure and greedy of praise, the fair ladies of the castle became the natural patronesses of the *mesnie* or household of men-at-arms and jongleurs whom their husbands maintained in their castles. Songs of love addressed to them soon became an accepted and almost conventional form of literature; and, as in social position the authors were generally far below those to whom they directed their amorous plaints, this kind of poetry was always distinguished by great reserve and an essentially respectful style. From the beginning the sentiments, real or assumed, of the poets are expressed in such a refined and guarded style that some historians, overestimating the virtue of the ladies of that time, have been misled to the belief that the love of the troubadour for the mistress of his thoughts was generally platonic and conventional.

The conditions under which Romanic poetry arose in the south of France being thus determined as accurately as the scarcity of documents allows, we now proceed to give a survey of the various forms of Provençal literature, chronological order being followed in each division. By this arrangement the wealth of each form will be better displayed; and, as it is rare for the same person to distinguish himself in more than one of them, there will be generally no occasion to introduce the same author in different sections. (*See* Edmond Faral, *Les Jongleurs en France au moyen âge,* Paris, 1910, and R. Menéndez Pidal, *Poesía juglaresca y juglares,* Madrid, 1924.)

Poetry of the Troubadours.—Centres of poetic activity are found first in Limousin and Gascony. In Limousin lived a viscount of Ventadour, Eble, who during the second part of William of Poitiers's life seems to have been brought into relation with him, and according to a contemporary historian, Geffrei, prior of Vigeois, *erat valde gratiosus in cantilenis.* We possess none of his compositions; but under his influence Bernart of Ventadour was trained to poetry. Bernart gained the love of the lady of Ventadour, and when on the discovery of their amour he had to depart elsewhere, received a gracious welcome from Eleanor of Guienne, consort (from 1152) of Henry II of England. Of Bernart's compositions we possess about 50 songs of elegant simplicity, some of which may be taken as the most perfect specimens of love poetry Provençal literature has ever produced. At the same period, or earlier, flourished Cercamon, a Gascon, who composed, says his old biographer, "pastorals" according to the ancient custom (*pastorelas a la uzansa antiga*). Among the earliest trouba-

dours is Marcabrun, a pupil of Cercamon's, from whose pen we have about 40 pieces, those which can be approximately dated ranging from 1135 to 1148 or thereabout. His songs, several of which are historical, are free from the commonplaces of their class, and contain curious strictures on the corruptions of the time.

We cannot here do more than enumerate the leading troubadours and briefly indicate in what conditions their poetry was developed and through what circumstances it fell into decay and finally disappeared: Peter of Auvergne (Peire d'Alvernha), who in certain respects must be classed with Marcabrun; Arnaut Daniel, remarkable for his complicated versification, the inventor of the *sestina*, a poetic form for which Dante and Petrarch express an admiration difficult for us to understand; Arnaut of Mareuil, who, while less famous than Arnaut Daniel, certainly surpasses him in elegant simplicity of form and delicacy of sentiment; Bertran de Born, now the most generally known of all the troubadours on account of the part he is said to have played both by his sword and his *sirventescs* in the struggle between Henry II of England and his rebel sons, though the importance of his part in the events of the time seems to have been greatly exaggerated; Peire Vidal of Toulouse, a poet of varied inspiration who grew rich with gifts bestowed on him by the greatest nobles of his time; Guiraut de Borneil, *lo maestre dels trobadors*, and at any rate master in the art of the so-called "close" style (*tobar clus*), though he has also left us some songs of charming simplicity; Gaucelm Faidit, from whom we have a touching lament (*planh*) on the death of Richard Coeur de Lion; Folquet of Marseilles, the most powerful thinker among the poets of the south, who from being a troubadour became first a monk, then an abbot, and finally bishop of Toulouse (d. 1231).

The troubadours could hardly expect to obtain a livelihood from any other quarter than the generosity of the great. It will consequently be well to mention the most important at least of those princes who are known to have been patrons and some of them practisers of the poetic art. They are arranged approximately in geographical order, and after each are inserted the names of those troubadours with whom they were connected.

France.—Eleanor of Guienne, Bernart de Ventadour (Ventadorn); Henry Curtmantle, son of Henry II of England, Bertran de Born (?); Richard Coeur de Lion, Arnaut Daniel, Piere Vidal, Folquet of Marseilles, Gaucelm Faidit; Ermengarde of Narbonne (1143–1192), Bernart de Ventadour, Peire Rogier, Peire d'Alvernha; Raimon V, count of Toulouse (1143–1194), Bernart de Ventadour, Peire Rogier, Peire Raimon, Hugh Brunet, Peire Vidal, Folquet of Marseilles, Bernart de Durfort; Raimon VI, count of Toulouse (1194–1222), Raimon de Miraval, Aimeric de Pegulhan, Aimeric de Belenoi, Ademar lo Negre; Alphonse II, count of Provence (1185–1209), Elias de Barjols; Raimon Berenger IV, count of Provence (1209–1245), Sordel; Barral, viscount of Marseilles (d. *c.* 1192), Peire Vidal, Folquet de Marseilles; William VIII, lord of Montpellier (1172–1204), Peire Raimon, Arnaut de Mareuil, Folquet de Marseilles, Guiraut de Calanson, Aimeric de Sarlat; Robert, dauphin of Auvergne (1169–1234), Peirol, Perdigon, Pierre de Maensac, Gaucelm Faidit; Guillaume du Baus, prince of Orange (1182–1218), Raimbaut de Vacqueiras, Perdigon; Savaric de Mauléon (1200–1230), Gaucelm de Puicibot, Hugh de Saint Circq; Blacatz, a Provençal noble (1200?–1236), Cadenet, Jean d'Aubusson, Sordel, Guillem Figueira; Henry I, count of Rodez (1208–1222?), Hugh de Saint Circq; perhaps Hugh IV, count of Rodez (1222?–1274) and Henry II, count of Rodez (1274–1302), Guiraut Riquier. Folquet de Lunel, Serverí de Girone, Bertran Carbonel; Nunyo Sanchez, count of Roussillon (d. 1241), Aimeric de Belenoi; Bernard IV, count of Astarac (1249–1291), Guiraut Riquier, Amanieu de Sescas.

Spain.—Alphonse II, king of Aragon (1162–1196), Peire Rogier, Peire Raimon, Peire Vidal, Cadenet, Guiraut de Cabreira, Elias de Barjols, the monk of Montaudon, Hugh Brunet; Peter II, king of Aragon (1196–1213), Raimon de Miraval, Aimeric de Pegulhan, Perdigon, Ademar lo Negre, Hugh of Saint Circq; James I, king of Aragon (1213–1276), Peire Cardinal, Bernart Sicart de Maruejols, Guiraut Riquier, At de Mons; Peter III king of Aragon (1276–1285), Paulet of Marseilles, Guiraut Riquier, Serveri de Girone; Alphonso IX, king of Leon (1138–1214), Peire Rogier, Guiraut de Borneil, Aimeric de Pegulhan, Hugh de Saint Circq; Alphonso X, king of Castile (1252–1284), Bertran de Lamanon, Bonifaci Calvo, Guiraut Riquier, Folquet de Lunel, Arnaut Plages, Bertran Carbonel.

Italy.—Boniface II, marquis of Montferrat (1192–1207), Peire Vidal, Raimbaut de Vacqueiras, Elias Cairel, Gaucelm Faidit (?); Frederick II, emperor (1215–1250), Jean d'Aubusson, Aimeric de Pegulhan, Guillem Figueira; Azzo VI, marquis of Este (1196–1212), Aimeric de Pegulhan, Rambertin de Buvalelli; Azzo VIII, marquis of Este (1215–1264), Aimeric de Pegulhan.

The first thing that strikes one in this list is that, while the troubadours find protectors in Spain and Italy, they do not seem to have been welcomed in French-speaking countries. This, however, must not be taken too absolutely. Provençal poetry was appreciated in the north of France. There is reason to believe that when Constance, daughter of one of the counts of Arles, was married in 998 to Robert, king of France, she brought along with her Provençal jongleurs. Poems by troubadours are quoted in the French romances of the beginning of the 13th century; some of them are transcribed in the old collections of French songs, and the preacher Robert de Sorbon informs us in a curious passage that one day a jongleur sang a poem by Folquet of Marseilles at the court of the king of France.

The decline and fall of troubadour poetry was mainly due to political causes. When about the beginning of the 13th century the Albigensian War had ruined a large number of the nobles and reduced to lasting poverty a part of the south of France, the profession of troubadour ceased to be lucrative. It was then that many of those poets went to spend their last days in the north of Spain and Italy, where Provençal poetry had for more than one generation been highly esteemed. Following their example, other poets who were not natives of the south of France began to compose in Provençal, and this fashion continued until, about the middle of the 13th century, they gradually abandoned the foreign tongue in northern Italy, and somewhat later in Catalonia, and took to singing the same airs in the local dialects. About the same time in the Provençal region the flame of poetry had died out save in a few places—Narbonne, Rodez, Foix and Astarac—where it kept burning feebly for a little longer. In the 14th century composition in the language of the country was still practised; but the productions of this period are mainly works for instruction and edification. As for the poetry of the troubadours, it was dead forever.

Form.—Originally the poems of the troubadours were intended to be sung. The poet usually composed the music as well as the words; and in several cases he owed his fame more to his musical than to his literary ability. Two manuscripts preserve specimens of the music of the troubadours, but, though the subject has been carefully investigated, we are not able to form a clear opinion of the originality and of the merits of these musical compositions. The following are the principal poetic forms which the troubadours employed. The oldest and most usual generic term is *vers*, by which is understood any composition intended to be sung, no matter what the subject. At the close of the 12th century it became customary to call all verse treating of love *canso*—the name *vers* being then more generally reserved for poems on other themes. The *sirventesc* differs from the *vers* and the *canso* only by its subject, being for the most part devoted to moral and political topics. The *tenson* is a debate between two interlocutors, each of whom has a stanza in turn. The *partimen* (Fr. *jeu parti*) is also a poetic debate, but it differs from the tenson in so far that the range of debate is limited. This poetic game is mentioned by William, count of Poitiers, at the end of the 11th century. The *pastoreta*, afterwards *pastorela*, is in general an account of the love adventures of a knight with a shepherdess. All these classes have one form capable of endless variations: five or more stanzas and one or two envois. The *dansa* and *balada*, intended to mark the time in dancing, are pieces with a refrain. The *alba*, which has also a refrain, is, as the name indicates, a waking or morning song

at the dawning of the day. All those classes are in stanzas. The *descort* is not thus divided, and consequently it must be set to music right through. Its name is derived from the fact that, its component parts not being equal, there is a kind of "discord" between them. It is generally reserved for themes of love. Other kinds of lyric poems, sometimes with nothing new about them except the name, were developed in the south of France; but those here mentioned are the more important.

Chansons de Geste and Historical Poems.—Northern France remains emphatically the native country of the *chanson de geste;* but, although in the south different social conditions, a more delicate taste, and a higher state of civilization prevented a similar profusion of tales of war and heroic deeds, Provençal literature has some highly important specimens of this class. The first place belongs to *Girart de Roussillon,* a poem of ten thousand lines, which relates the struggles of Charles Martel with his powerful vassal the Burgundian Gerard of Roussillon. The existing recension seems to have originated on the borders of Limousin and Poitou; but it is a recast of an older poem no longer extant, probably either of French or at least Burgundian origin. To Limousin also seems to belong the poem of *Aigar and Maurin* (end of the 12th century). Of less heroic character is the poem of *Daurel and Beton* (first half of the 13th century). Midway between legend and history may be classified the Provençal *Chanson of Antioch,* a mere fragment of which, 700 verses in extent, has been recovered in Madrid and published in *Archives de l'Orient latin,* vol. ii. This poem (*see* G. Paris, in *Romania,* xxii. 358), is one of the sources of the Spanish compilation *La gran conquista de Ultramar.* To history proper belongs the Chanson of the crusade against the Albigensians, which, in its present state, is composed of two poems one tacked to the other: the first, containing the events from the beginning of the crusade till 1213, is the work of a cleric named William of Tudela, a moderate supporter of the crusaders; the second, from 1213 to 1218, is by a vehement opponent of the enterprise. The language and style of the two parts are no less different than the opinions. Finally, about 1280, Guillaume Anelier, a native of Toulouse, composed, in the *chanson de geste* form, a poem on the war carried on in Navarre by the French in 1276 and 1277. It is an historical work of little literary merit. All these poems are in the form of *chansons de geste,* viz. in stanzas of indefinite length, with a single rhyme. *Gerard of Roussillon, Aigar and Maurin* and *Daurel and Beton* are in lines of ten, the others in lines of twelve syllables. The peculiarity of the versification in *Gerard* is that the pause in the line occurs after the sixth syllable, and not, as is usual, after the fourth.

Narrative Poems.—We possess but three Provençal romances of adventure: *Jaufré* (composed in the middle of the 13th century and dedicated to a king of Aragon, possibly James I.), *Blandin of Cornwall* and *Guillem de la Barra.* Connected with the romance of adventure is the novel (in Provençal *novas,* always in the plural), which is originally an account of an event "newly" happened. Some of those novels which have come down to us may be ranked with the most graceful works in Provençal literature; two are from the pen of the Catalan author Raimon Vidal de Besalú. One, the *Castia-gilos* (the chastisement of the jealous man), is a treatment, not easily matched for elegance, of a frequently-handled theme—the story of the husband who, in order to entrap his wife, takes the disguise of the lover whom she is expecting and receives with satisfaction blows intended, as he thinks, for him whose part he is playing; the other, *The Judgment of Love,* is the recital of a question of the law of love, departing considerably from the subjects usually treated in the novels. Mention may also be made of the novel of *The Parrot* by Arnaut de Carcassonne, in which the principal character is an eloquent parrot, who assists the amorous enterprises of his master. Novels came to be extended to the proportions of a long romance. *Flamenca,* which belongs to the novel type, has still over eight thousand lines, though the only ms. of it has lost some leaves both at the beginning and at the end. This poem, composed in all probability in 1234, is the story of a lady who by very ingenious devices, not unlike those employed in the *Miles gloriosus* of Plautus, eludes the vigilance of her jealous husband. No book in mediaeval literature betokens so much quickness of intellect or is so instructive in regard to the manners and usages of polite society in the 13th century. From the south of France the novel spread into Catalonia, where we find in the 14th century a number of novels in verse very similar to the Provençal ones, and into Italy, where in general the prose form has been adopted.

Didactic and Religious Poetry.—The more important works are: Daude de Prades (early 13th century), *Auzels cassadors,* one of the best sources for the study of falconry; a translation by Raimon d'Avignon (about A.D. 1200) of Rogier of Parme's "Surgery" (*Romania,* x. 63 and 496); the Boethius poem (unfortunately a mere fragment) already mentioned as one of the oldest documents of the language, and really a remarkable work; an early (12th century?) metrical translation of the famous *Disticha de moribus* of Dionysius Cato (*Romania,* xxv. 98 and xxix. 445). More original are some compositions of an educational character known under the name of *ensenhamenz,* and, in some respects, comparable to the English nurture-books. The most interesting are those of Garin le Brun (12th century), Arnaut de Mareuil, Arnaut Guilhem de Marsan, Amanieu de Sescas. Their general object is the education of ladies of rank. Of metrical lives of saints we possess about a dozen (see *Histoire littéraire de la France,* vol. xxxii.), among which two or three deserve a particular attention: the life of Sancta Fides (A. Thomas and E. Hoepffner's editions), written early in the 12th century; the life of St. Enimia (13th century), by Bertran of Marseilles (C. Brunel's edition) and that of St. Honorat of Lerins by Raimon Feraud (about 1300), which is distinguished by variety and elegance of versification, but it is almost entirely a translation from Latin. Lives of saints (St. Andrew, St. Thomas the Apostle, St. John the Evangelist) form a part of a poem, strictly didactic, which stands out by reason of its great extent (nearly 35,000 verses) and the somewhat original conception of its scheme—the *Breviari d'amor,* a vast encyclopaedia, on a theological basis, composed by the Minorite friar Matfre Ermengaut of Béziers ca. 1288–1300.

Drama.—The dramatic literature of southern France consists of mysteries and miracle plays seldom exceeding two or three thousand lines, which never developed into the enormous dramas of northern France, whose acting required several consecutive days. Generally those plays belong to the 15th century or to the 16th. Still, a few are more ancient and may be ascribed to the 14th century or even to the end of the 13th. The oldest appears to be the *Mystery of St. Agnes* (edited by Bartsch, 1869), written in Arles. Somewhat more recent, but not later than the beginning of the 14th century, is a Passion of Christ (not yet printed) and a mystery of the Marriage of the Virgin, which is partly adapted from a French poem of the 13th century (see *Romania* xvi. 71). A manuscript, discovered in private archives (printed by Jeanroy and Teulié, 1893), contains not less than 16 short mysteries, three founded on the Old Testament, 13 on the New. They were written in Rouergue and are partly imitated from French mysteries. At Manosque (Basses Alpes) was found a fragment of a *Ludus sancti Jacobi,* inserted in a register of notarial deeds (printed by C. Arnaud, Marseilles, 1858). The region comprised between the Rhone and the Var seems to have been particularly fond of representations of this sort, to judge by the entries in the local records (see *Romania* xxvii. 400). At the close of the 15th and the beginning of the 16th centuries many mysteries were played in that part of Dauphiné which corresponds to the present department of Hautes-Alpes. Five mysteries of this district, composed and played somewhere about 1500 (the mysteries of St. Eustace, of St. Andrew, of St. Pons, of SS. Peter and Paul and of St. Anthony of Vienne), have come down to us, and have been edited by Abbé Fazy (1883), the four others by Canon P. Guillaume (1883–1888). The influence of the contemporary French sacred drama may to some extent be traced in them.

Prose.—In the 12th century we find in Languedoc sermons, whose importance is more linguistic than literary (*Sermons du XII^e siècle en vieux provençal,* ed. by F. Armitage, Heilbronn, 1884). About the same time, in Limousin, were translated chapters xiii.–xvii. of St. John's Gospel (Bartsch, *Chrestomathie provençale*). Various translations of the New Testament and of some

parts of the Old have been done in Languedoc and Provence during the 13th and 14th centuries (*see* S. Berger, "Les Bibles provençales et vaudoises," *Romania* xviii. 353; and "Nouvelles recherches sur les Bibles provençales et catalanes," *ibid.* xix. 505). The Provençal prose rendering of some lives of saints made in the early part of the 13th century (*Revue des langues romanes,* 1890) is more interesting from a purely linguistic than from a literary point of view. To the 13th century belong certain lives of the troubadours intended to be prefixed to, and to explain their poems. Many of them were written before 1250, when the first anthologies of troubadour poetry were compiled; and some are the work of the troubadour Hugh of Saint Circq. Some were composed in the north of Italy, at a time when the troubadours found more favour east of the Alps, than in their own country. Considered as historical documents these biographies are of a very doubtful value. To the same period must be assigned *Las Razos de trobar* of the troubadour Raimon Vidal de Besalú (an elegant little treatise touching on various points of grammar and the poetic art), the *Donatz proensals* of Hugh Faidit, and the *Life of St. Douceline,* who died in 1274, near Marseilles, and founded an order of Béguines.

The leading prose-work of this period is the treatise on grammar, poetry and rhetoric known by the name of *Leys d'amors.* (*See* J. Anglade, *Las leys d'amors,* 4 vol., *Toulouse,* 1919–1920.) The *Leys d'amors* (composed in Toulouse circa 1350) was to be the starting-point and rule of the new poetry; it is the best production of this abortive renaissance. The decay of Provençal literature, caused by political circumstances, arrived too soon to allow of a full development of prose. This accounts, in some measure for the complete absence of historical compositions. The 14th and 15th centuries were in no respect a prosperous period for literature in the south of France. In the 15th century people began to write French both in verse and prose; and from that time Provençal literature became a thing of the past. From the 16th century such poetry as is written in the vernacular of southern France is generally dependent on French influence. The connection with ancient Provençal literature is entirely broken.

See Joseph Anglade, *Les Troubadours,* Paris, 1908; and *Histoire sommaire de la littérature méridionale au moyen âge.* Both volumes contain a bibliography. Documents and dissertations on various points of Provençal literature will be found in almost all the volumes of *Romania* (Paris, in progress since 1872, 8vo), and the *Revue des langues romanes* (Montpellier, in progress since 1870, 8vo). *See* also the other journals devoted to the Romanic languages, *passim.*

(X., L. B.)

MODERN PROVENÇAL LITERATURE[1]

Provençal literature never died out entirely. The Academy of Toulouse, founded in 1324, was flourishing in the 14th century, and, after many vicissitudes, is flourishing still. The poets crowned by this body between 1324 and 1498 stand in the same relation to the troubadours as the *Meistersinger* do to the *Minnesänger:* academic correctness takes the place of inspiration. The institution flourished, even to the extent of establishing branches in Catalonia and Majorca; and in 1484, when its prosperity was threatened, a semi-fabulous person, Clémence Isaure, is said to have brought about a revival by instituting fresh prizes. The town of Toulouse never ceased to supply funds of some kind. In 1513 French poems were first admitted in the competitions, and under Louis XIV. (from 1679) these were alone held eligible. This arrangement held good till 1893, when the town very properly transferred its patronage to a new *Escolo moundino,* but very soon restored its support to the older institution, on learning that Provençal poetry was again to be encouraged. In the two centuries that followed the glorious mediaeval period we have a succession of works, chiefly of a didactic and edifying character, which served to keep alive some kind of literary tradition. Religious mystery plays, which, though dull to us, probably gave keen enjoyment to the people, represent a more popular genre; the latest that have come down to us may be placed between the years 1450–1515.

[1] In accordance with general usage, we are employing the term Provençal for the whole of the south of France, save where special reservation is made.

In the 16th century there are signs of a revival and we may single out the following: the Gaston Pey de Garros who translated in 1565 the psalms into his dialect, and two years later published a volume of poems; Auger Gaillard (*c.* 1530–1595); du Bartas (in his trilingual *Salut,* 1579); Louis Bellaud de la Bellaudière (1532–1588).

Post-Renaissance.—Later on come: Claude Brueys (1570–1650), remarkable chiefly for comedies that deal largely with duped husbands (*Jardin deys musos provensalos,* not published till 1628); Gaspard Zerbin (*La Perlo deys musos et coumedies prouvensalos,* 1655). The most consistently popular form of poetry in the south of France was always the *noël.* Nicholas Saboly (1614–1675), produced the best pieces of this class. In Languedoc four poets are cited as the best of the age—Goudelin, Michel, Sage and Bonnet. This is certainly so in the case of Pierre Goudelin (Goudouli, 1579–1649), of Toulouse, the most distinguished name in south French literature between the period of the troubadours and that of Jasmin. Goudelin essayed and was successful in almost every short genre (*Lou Ramelet Moundi,* 1617, republished with additions till 1678), the piece of his which is most generally admired being the stanzas to Henri IV. Other writers worth mentioning in the 17th century are: Jean Michel, of Nîmes; Daniel Sage, of Montpellier (*Las Foulies,* 1650); the *avocat* Bonnet, author of the best among the open air plays that were annually performed at Béziers on Ascension day: a number of these (dated 1616–1657) were subsequently collected, but none can compare with the opening one, Bonnet's *Jugement de Pâris;* Nicolas Fizes, of Frontignan, whose vaudeville, the *Opéra de Frontignan* (1670), dealing with a slight love intrigue, and an idyllic poem on the fountain of Frontignan, show a real poetic gift. A number of Toulouse poets, mostly *lauréats* of the Academy, may be termed followers of Goudelin: of these François Boudet, who composed an ode, *Le Trinfe del Moundi* (1678), in honour of his native dialect deserves mention. The classical revival that may be noted about this time is also generally ascribed to Goudelin's influence. Its most distinguished representative was Jean de Valès, of Montech, who made excellent translations from Virgil and Persius, and wrote a brilliant burlesque of the former in the manner of Scarron (*Virgile deguisat,* 1648).

The best of the pastoral poets was François de Cortete (1571–1655), of Prades, whose comedies, *Ramounet* and *Miramoundo* (published, unfortunately with alterations, by his son in 1684), are written with such true feeling and in so pure a style that they can be read with real pleasure. A comedy of his dealing with Sancho Panza in the palace of the Duke has been edited. Daubasse (1664–1727), of Quercy, who belonged to the working classes, was patronized by the nobility in exchange for panegyrics. Gascony produced two typical works in the 17th century: Ader's *Gentilhomme gascoun* (1610) and G. d'Astros's *Trinfe de la lengo gascouo* (1642). Gabriel Bedout (*Parterre gascoun,* 1642) is chiefly noted for his amorous *solitari.* Louis Baron (b. 1612), celebrated with great tenderness his native village of Pouyloubrin.

In the 18th century the number of authors is much larger, but the bulk of good work produced is not equally great in proportion. The priests are mainly responsible for the literary output of Languedoc. The chief of the band is the Abbé Favre (1727–1783), the prior of Celleneuve, whose *Ou sermoun de Moussu Sistre* delivered a drunken priest against intemperance, is a masterpiece. He also wrote a successful mock-heroic poem (*Siège de Caderouss*) travesties of Homer and Virgil, a prose novel depicting the country manners of the time (*Histouèro de Jean-l'an-prés*), and two comedies, which likewise give a vivid picture of the village life he knew so well. Two genuine poets are the brothers Rigaud of Montpellier: Auguste's (1760–1835) description of a vintage is deservedly famous; and Cyrille (1750–1824) produced an equally delightful poem in the *Amours de Mounpëié.* Pierre Hellies of Toulouse (d. 1724) a poet of the people, whose vicious life finds an echo in his works, has a certain rude charm, at times distantly recalling Villon. In Provence Toussaint Gros (1698–1748), of Lyons, holds undisputed sway. His style and language are admirable, but unfortunately he wasted his gifts largely on trivial *pièces d' occasion.* Coye's (1711–1777) comedy, *ou Novy*

para, is bright and still popular, while Germain's description of a visit paid by the ancient gods to Marseilles (*Bourrido dei Dious,* 1760) has considerable humour. In Gascony the greatest poet is Cyrien Despourrins (1698–1755).

The 19th Century.—The Revolution produced a large body of literature, but nothing of lasting interest. Scholars like Raynouard (1761–1863), of Aix, occupied themselves with the brilliant literary traditions of the middle ages; newspapers sprang up (the Provençal *Boüil-Abaisso,* started by Désanat, and the bilingual *Lou Tambourin et le menestrel,* edited by Bellot, both in 1841); poets banded together and collected their pieces in volume form (thus, the nine *troubaire* who published *Lou Bouquet prouvençaou* in 1823). Much has been written about the *précurseurs de Félibrige,* and critics are sorely at variance as to the writers that most deserve this appellation. We shall not go far wrong if we include in the list Hyacinthe Morel (1756–1829), Louis Aubanel (1758–1842); Auguste Tandon, "the troubadour of Montpellier"; Fabre d'Olivet (1767–1825); Diouloufet (1771–1840); Jacques Azaïs (1778–1856); D'Astros (1780–1863), Castil-Blaze (1784–1857); the Marquis de Fare-Alais (1791–1846). While these writers were all more or less academic, and appealed to the cultured few, four poets of the people addressed a far wider public: Verdié (1779–1820), of Bordeaux, who wrote comic and satirical pieces; Jean Reboul (1796–1864), the baker of Nîmes, who never surpassed his first effort, *L'Ange et l'enfant* (1828); Victor Gelu (1806–1885), relentless and brutal, but undeniably powerful of his kind (*Fenian et Grouman; dix chansons provençales,* 1840); and, greatest of them all, the true and acknowledged forerunner of the *félibres,* Jacques Jasmin (*q.v.*).

Roumanille and Mistral.—In 1845 Joseph Roumanille (1818–1891) of Saint-Remy became usher in a small school at Avignon, which was attended by Frédéric Mistral (*q.v.*). Roumanille had composed some pieces in French; but, finding that his old mother could not understand them, he determined thenceforth to write in his native dialect only. These poems revealed a new world to young Mistral, and spurred him on to the resolve that became the one purpose of his life—*de remettre en lumière et conscience de sa gloire cette noble race qu'en plein '89 Mirabeau nomme encore la nation provençale.* There is no doubt that Mistral's is the more puissant personality, and that his finest work towers above that of his fellows; but in studying the Provençal renaissance, Roumanille's great claims should not be overlooked, and they have never been put forward with more force than by Mistral himself (in the preface of his *Isclos d'oro*). Roumanille's secular verse cannot fail to appeal to every lover of pure and sincere poetry (*Li Margaritedo,* 1836–1847; *Li Sounjarello,* 1852; *Li Flour de Sauvi,* 1850–1859, etc.), his *noëls* are second only to those of Saboly, his prose works (such as *Lou mege de Cucugnan,* 1863) sparkling with delightful humour. He it was who in 1852 collected and published *Li Prouvençalo,* an anthology in which all the names yet to become famous, and most of those famous already (such as Jasmin), are represented. In 1853 he was one of the enthusiastic circle that had gathered round J. B. Gaut at Aix, and whose literary output is contained in the *Roumavagi dei Troubaire* and in the shortlived journal *Lou gay saber* (1854). At the same time the first attempt at regulating the orthography of Provençal was made by him (in the introduction to his play, *La Part dou bon Dieu,* 1853). And in 1854 he was one of the seven poets who, on May 21, foregathered at the castle of Font-ségugne, near Avignon, and founded the *Félibrige.* (*See* Emile Ripert, *La Renaissance Provençale.*) The other six were Mistral, Aubanel, A. Mathieu (a schoolfellow of Mistral's at Avignon), E. Garcin, A. Tavan and P. Giera (owner of the castle). Of these, Théodore Aubanel (1829–1886, of Avignon, son of a printer and following the same calling) has alone proved himself worthy to rank with Mistral and Roumanille. "Zani," the girl of his youthful and passionate love, took the veil; and this event cast a shadow over his whole life, and determined the character of all his poetry (*Lou mióugrano entre-duberto,* 1860; *Li Fiho d'Avignoun,* 1883). His is, without a doubt, the deepest nature and temperament among the *félibres,* and his lyrics are the most poignant. His powerful love drama *Lou pau dou peccat* was received with enthusiasm at Montpellier in 1878, and successfully produced (some years later in Arène's version) by Antoine at his Théâtre Libre.

We need not do more than glance at the work of the fourth of the group of poets who alone, amidst the numerous writers of lyrics and other works that attain a high level of excellence, appear to us to have so far secured permanent fame by the magnitude of their achievement. Félix Gras (1844–1891) settled at Avignon in his youth. His rustic epic, *Li Carbounié* (1876) is full of elemental passion and abounds in fine descriptions of scenery, but it lacks proportion. The heroic *geste* of *Toloza* (1882), in which Simon de Montfort's invasion of the south is depicted with unbounded vigour and intensity, shows a great advance in art. *Li Roumancero provençal* (1887) is a collection of poems instinct with Provençal lore, and in *Li Papalino* (1891) we have some charming prose tales that bring to life again the Avignon of the popes. Finally, the poet gave us three tales dealing with the period of the Revolution (*Li Rouge dou miejour,* etc.).

Since the end of the 19th century the Félibrige has considerably developed: it now constitutes important groups in the different parts of Southern France from the Pyrenees to Auvergne, Velay and Dauphiné.

These groups represent the most varied opinions in politics and religion, and for the expression of their ideas they resort to the whole range of dialects and patois actually used in southern France.

The spirit of the movement is purely literary; it has never been expressed with greater terseness, force and truth than in the three verses set by Félix Gras at the head of his *Carbounié:* "I love my village more than thy village; I love my Provence more than thy province; I love France more than all."

See Emile Ripert, *Le Félibrige* (Paris, 1924); contains an excellent bibliography. (H. O.; L. B.)

PROVENCE, a province in the southeast of ancient France, bounded on the north by the Dauphiné, on the east by the Alps and Italy, on the west by the Rhône and on the south by the Mediterranean sea. About 600 B.C., according to tradition, some traders from Phocaea founded the Greek colony of Massalia (Marseilles). Other colonies in the neighbourhood, such as Antibes, Agde and Nice, originated in this settlement. During the wars which followed, the inhabitants of Massalia asked assistance from the Romans, who thus made their first entry into Gaul (125 B.C.) and conquered the territories between the Alps, the sea and the Rhône (with the province of Narbonne on the right bank of this river). These lands formed the Provincia Romana, and the name was retained by Provence. The town of Aix (Aquae Sextiae) was founded to form the capital of this conquered land. Under the empire the territory of the former Provincia was divided into the new provinces of Narbonensis II, of the Maritime Alps and of Viennensis and formed an important centre of Roman learning and civilization. Arles was made the chief town of the province, becoming after the capture of Trier by the barbarians (A.D. 418) the capital of Gaul. By the 5th century bishoprics had been founded in all the cities of Provence.

At the beginning of that century Provence was attacked by the Visigoths. In 476 Arles was captured by Euric I, and the country south of the Durance thus came definitely under Visigothic rule. The more northern cities, such as Orange, Apt and Trois-Châteaux, were joined to the kingdom of Burgundy. About 510 Visigothic Provence was ceded to Theodoric, king of the Italian Ostrogoths; and soon afterward the Ostrogoths extended their lands in the north as far as Gap and Embrun. Witigis, king of the Ostrogoths, ceded Provence to the kings of the Franks about 537, when the northern cities and those on the coast (Arles, Marseilles, Toulon, Antibes, Nice) were given back to Burgundy, while a narrow strip of territory, with Avignon, Apt, Cavaillon, Riez, etc., extending from the west to the east as far as the Alps, was added to the kingdom of Austrasia.

In the 8th century western Provence was for a time conquered by Arabs from Spain. In 739 they were expelled by Charles Martel, who brought the country definitely under Frankish rule. Under Charlemagne and Louis the Pious the history of Provence was incorporated with that of the rest of the empire and became more and more subject to the incursions of the Saracens. After

the partition of Verdun (843) it fell to the portion of the emperor Lothair. Later it went to his son, the emperor Louis II; and finally in 875 it passed to Charles the Bald, who handed it over to his brother-in-law Boso (879). The latter bore the title of king, and thus arose the kingdom of Provence (Provence, Viennois, Lyonnais and Vivarais), sometimes called Cisjuran Burgundy.

After some years of trouble the kingdom was given, in the 10th century, to Rudolph II of Burgundy, so that the kingdom of Burgundy now extended from the Aar to the Mediterranean. But under Rudolph's successors control became weaker and weaker, until Provence passed to the German kings, who then took the title of king of Arles (*see* ARLES, KINGDOM OF).

Local Countships.—At the beginning of the 10th century Provence was in a state of complete disorganization. All the real power was in the hands of local counts. It is probable that from the 9th century several of the Provençal countships were united under one count and that the count of Arles had the title of duke, or marquis, and exercised authority over the others. In the middle of the 10th century this position was held by another Boso, of unknown origin, who left it to his two sons William and Roubaud (Rotbold).

From the end of the 10th century the descendants of the two brothers, without making any partition, ruled over the different countships of Provence; only one of them, however, bore the title of marquis. The counts of Provence had, from about the middle of the 11th century, a tendency to add the name of their usual residence after their title, and thus the lordships, known later under the names of the countships of Provence, of Nice and of Venaissin grew up. At last, by the marriage of Douce, the heiress, in 1112 to Raymund-Berengar III (Ramón Berenguer), count of Barcelona, the marquisate of Provence with the overlordship of this region passed to the house of Barcelona. The definite establishment of the countships of Provence, Venaissin and Forcalquier belongs to this period.

After the death of Raymund-Berengar IV (II of Provence) in 1162, his son Alphonso II, king of Aragon, took the title of count of Provence. His succession was disputed by the count of Toulouse, Raymund V. Most of the lay and ecclesiastical lords of Provence recognized Alphonso, who in 1176 signed a treaty with his competitor, by which Raymund V sold his rights to the king of Aragon.

Alphonso was represented in Provence by his brothers Raymund-Berengar III (of Provence) and Sancho, in turn, and in 1193 by his son Alphonso, who inherited Provence but not Aragon on his father's death in 1196. This Alphonso gave Aragon and Catalonia to his brother Peter (Pedro) and kept only Provence for himself; but on the death of his father-in-law, Count William II, in 1208, whose son had been disinherited, he added to it the county of Forcalquier. It was not until after his death (1209), during the minority of his son Raymund-Berengar IV, that Provence was involved in the struggle of the count of Toulouse against Simon de Montfort, when the part played by the city of Avignon in the Albigensian movement finally led to the expedition of Louis VIII of France against the town (*see* ALBIGENSES).

Raymund-Berengar had also to fight against Raymund VII, count of Toulouse, who had received from the emperor in 1230 the countship of Forcalquier. The intervention of St. Louis, who in 1234 had married Margaret, the eldest daughter of the count of Provence (the second, Eleanor, married Henry III of England in 1236), put an end to the designs of the count of Toulouse. Raymund-Berengar died in 1245, leaving a will by which he named as his heiress his fourth daughter, Beatrice, who shortly afterward, in 1246, married the celebrated Charles of Anjou (*see* CHARLES I, king of Naples), brother of the king of France. After her death, in 1267, Charles still maintained his rights in Provence. The countship of Venaissin was left to him by his sister-in-law, Joan, countess of Toulouse, but in 1272 King Philip III took possession of it, giving it up in 1274 to Pope Gregory X, who had claimed it for the Roman Church in pursuance of the treaty of 1229 between Raymund VII of Toulouse and St. Louis.

Charles of Anjou was continually occupied with his kingdom of Naples. His government of Provence was marked by his struggles with the towns. In the first part of the 12th century the towns of Provence began to form municipal administrations and consulates, independent of the viscounts, who in theory represented the authority of the count in the towns. Marseilles, Arles, Tarascon, Avignon (whose consulate laws date from the 12th century), Brignoles and Grasse had become self-governing and elected their magistrates, sometimes negotiating with the count, as a power with a power, and concluding political or commercial treaties without consulting him. The city of Nice, which was joined to Provence in 1176, had retained its freedom. This state of affairs was in direct opposition to the arbitrary policy of Charles of Anjou. In 1251 he seized Arles and Avignon and placed them under a *viguier* (vicar) nominated by himself. In 1257 Marseilles was also subdued, and ministers nominated by the court performed their duties side by side with the municipal officials.

Annexation to France.—The successors of Charles of Anjou were chiefly interested in maintaining their rights over the kingdom of Naples. Charles II (ruled 1285–1309) lived in Provence during the latter years of his reign and tried to introduce reforms into the administration of justice and finance. Robert of Calabria (1309–43), his son, was succeeded by his granddaughter Joanna I, widow of Andrew of Hungary, who sold her rights over the city of Avignon (where the popes settled from 1309 to 1377 and subsequently during the great schism) to Clement VI in 1348 to raise money to continue the struggle against the house of Aragon in Naples. The emperor Charles IV visited Avignon and had himself crowned king of Arles in 1365. He gave up his claims to Louis I, duke of Anjou, brother of Charles V of France, but the expedition which this prince made to take possession of Provence only resulted in the seizure of Tarascon and failed before Arles (1368).

Joanna had first nominated as her heir Charles of Anjou-Gravina, duke of Durazzo, her nephew by marriage; but when he took sides against her claim to the kingdom of Naples she nominated instead Louis of Anjou as her eventual successor (1380). Louis took possession of Provence, while Charles of Durazzo made the queen prisoner at Naples and gave orders for her to be put to death (1382). Louis of Anjou also made an expedition to Naples, but did not arrive till after her death; he died in 1384. His son Louis II (ruled 1384–1417), only resident in Provence toward the end of his life, established a *parlement* in 1415. The wars carried on by his successor, Louis III (ruled 1417–34), against the kings of Aragon, his rivals at Naples, were the cause of the temporary ruin of Marseilles by the Aragonese fleet. René I (*q.v.*), duke of Anjou and Lorraine, Louis's brother and successor, after an unsuccessful attack on Naples (1460–61) retired to France, but after 1471 generally resided in Provence, where he built the castle of Tarascon and interested himself in art, literature and pastoral amusements. In 1474 he left his territories by will to his nephew Charles, count of Maine, who on his death in 1481 bequeathed Provence to Louis XI, king of France. Under Louis's successor, Charles VIII, Provence was definitely annexed to France, though even then it preserved a certain individuality. In laws relating to this country the sovereigns added to their title of king of France "and count of Provence and of Forcalquier," and Provence preserved a separate administrative organization.

Religious Troubles.—In the 16th century Protestantism made its appearance in Provence. A sentence passed in 1540 by the *parlement* of Provence against the heretics was carried out with great severity in 1545 by the president Jean de Maynier, baron d'Oppède, and the baron de la Garde. The movement drew a fair number of followers from the ranks of the lesser nobles. Charles IX's journey in Provence in 1567, followed by the establishment in the *parlement* at Aix of a court (*chambre*) in which Catholics and Protestants had an equal number of seats, led to a momentary cessation of hostilities. These were resumed between the Carcistes (Roman Catholics) and Razats (Protestants) but were again interrupted by the peace of 1576, which gave some guarantees to the Protestants, with La Seyne as a place of security, and also by the plague of 1579, which affected the whole country. The

League, on the other hand, made rapid progress in Provence, and the governor Bernard de Nogaret de La Valette and his brother Jean-Louis, duc d'Épernon (afterward governor also), vainly tried to pacify the country. La Valette and the party of the *Politiques* or Bigarrats were finally more or less reconciled to the Protestants; and, at the time of the death of Henry III, the struggle was no more than a question of local politics. In 1596 the religious wars in Provence were definitely ended by the capitulation of Marseilles.

Under Richelieu the restriction of local freedom led to a rising which Condé suppressed in 1630–31. At the time of the Fronde additional taxes were levied by the *parlement* at Aix, and a period of local unrest began which culminated in an insurrection at Marseilles in 1660 followed by the abolition of the last remaining municipal liberties of the town.

Provence was severely tried by the imperial invasions of 1706 and 1746 and the great plague of 1720.

Economic Development.—Throughout the middle ages, Provence was continually changing from the economic point of view. At the end of the ancient period and in Merovingian times it was a busy region with an important transit trade, the port of Marseilles being a commercial focus that connected Provence with the Italian ports and with the east. From the 7th century, however, trade underwent a serious crisis, caused in part by Arab expansion along the Mediterranean and by plundering of the Saracens, who blockaded the port and often attacked the coast of Provence. But as early as the 12th century trade came to life again, and the inland towns became local fairs. These fairs, however, did not enjoy so much prosperity as did those of other regions, because the important commercial roads—from Italy to Champagne and Flanders—did not cross this region. Nevertheless, Marseilles and Aigues-Mortes were ports in relation with Italy and the Latin east. At the beginning of the Angevin period (the end of the 13th century) the ports were busiest. Moreover, the towns acquired a considerable political importance and became great commercial and banking centres as well; such was the case with Avignon, where the papacy settled in the 14th century, and with Beaucaire, famous for its fairs. But later internal disturbances brought about a considerable falling off of these activities.

Administration.—Provence, with its own language and its law so closely related to Roman law, was quite separate from the other French provinces. Until 1639 it retained its provincial estates, the origin of which has been traced back to the 12th century. They met annually and included representatives of three orders: for the clergy, the archbishop of Aix, president ex officio of the estates, the other bishops of Provence and the abbots of St. Victor at Marseilles, of Montmajour and of Thoronet; for the nobility, all the men of noble birth until 1623, when this privilege was restricted to actual holders of fiefs; for the third estate, the members of the 22 chief towns of the *vigueries* (divisions corresponding to the *prévôtés* of the rest of France) and 15 other privileged places, among which were Arles and Marseilles. There were theoretically no taxes, but only supplies given freely by the estates and assessed by them. The administrative divisions of Provence were constantly changing. At the end of the *ancien régime* the government (*gouvernement*) of Provence, which corresponded to the *généralité* of Aix, was made up of eight *sénéchaussées:* those of lower Provence—Aix, Arles, Marseilles, Brignoles, Hyères, Grasse, Draguignan, Toulon; and four of upper Provence—Digne, Sisteron, Forcalquier, Castellane. For judicial purposes the *parlement* of Aix had replaced the former *conseil éminent* or *cour souveraine.* There was a *chambre des comptes* at Aix and also a *cour des aides.* A decree dated Dec. 22, 1789, divided Provence into the three departments of Bouches-du-Rhône, Basses-Alpes and Var; and in 1793 Vaucluse, the former county of Venaissin, which belonged to the pope, was added to these.

The boundaries of Var were modified in 1860 after the annexation of the county of Nice, when the department of the Alpes Maritimes was formed.

PROVERBS, BOOK OF. This Old Testament book falls into nine sections. Each of these has its special stylistic and other characteristics, some of them containing evident traces of compilation from earlier collections, one (as has only lately been recognized) being almost completely paralleled in an extant Egyptian book, while individual proverbs are found to bear traces of the "international" character of their origin and are variously related to the culture of Egypt, Babylonia, Greece, etc. (*see* WISDOM LITERATURE).

Moreover, the tradition preserved in the book itself which ascribed certain parts of the book to Solomon (x. 1, xxv. 1), the "sages" (xxii. 17, xxiv. 23), Agur (xxx. 2), King Lemuel's mother (xxxi. 2) militates against the view that any one author was responsible for the composition of these various sections of the book: the ascription to Solomon in i. 1 probably referred originally to chapters i.–ix.—though this was probably the last section to be compiled.

Wellnigh the only characteristics common to all sections of the book may be summed up under three heads and these are not confined to the Book of Proverbs but are to be found in nearly all the extant gnomic literature of the Hebrews—the presuppositions that "wisdom" comes from Jehovah, that wisdom is, or should be, the guiding principle of life, and that cardinal social virtues such as industry, thrift, discretion, truthfulness, honesty, chastity, thought for others, including the lower animals, should be inculcated. Consequently in its present form the book represents the last stage in a long compilatory history and provides many useful examples of Hebrew proverbial and gnomic thought at various stages of its development. The date of each section and subsection must be alternately determined by the character of its contents, the relation in which the latter stands to the extant gnomic literature of other peoples, and the stage or stages of moral and theological development reflected in it.

Chapters i.–ix.—The first section serves as an introduction to the whole book, but in origin it is of late date and its contents suggest that, like the book as a whole, it was compiled from more than one source. At times, for instance, the motive advanced for good conduct is moral and religious (*e.g.*, ii. 5–8): at times it is frankly utilitarian (*e.g.*, vi. 1–5). Instead of a series of unrelated proverbial couplets, such as those in the following section, comparatively long discourses follow on each other. The sage addresses his remarks to young men. Though not confining his warnings to these two offenses, he warns them more especially against highway robbery and adultery—unless indeed the latter is an only too thinly veiled warning against Hellenism (*cf.* "Madam Folly" in ch. ix. 13–18) conceived of as a prostitute enticing the uninstructed ("ye simple ones") from their allegiance to their true love, the "wisdom" which comes from Jehovah, incarnate, as it were, in His religion, Judaism. Somewhat similar warnings against woman's wiles are given by Egyptian sages such as Amenophis and Ptah-hoteph, and by the Mesopotamian author of the Wisdom of Aḥikar. The section is chiefly remarkable for the developed thought contained in viii. 1–31 as to "wisdom," its relation to God, the universe and man. It is perhaps more developed than, not only Eccles. xxiv. 1–19, but also the descriptions of it in the Book of Wisdom. "Wisdom" claims to have existed prior to the universe (*cf.* "in the beginning" with the first words of Gen. i. 1 and John i. 1) as a possession of God (viii. 22 sff.), to have witnessed the creation of the universe, and even to have acted as a clerk of the works or architect in the process of the creation, unless, as the parallelism of the verse makes probable, the vocalization of the Hebrew word translated "master workman" should be altered to justify the rendering "nursling." But it is questionable whether even here the Hebrew author does more than poetically *personify the principle* of wisdom: he scarcely gives it a real *hypostasis* and does not go so far in this direction as did Philo in his description of the Logos as "a second god."

It is not, however, outside the bounds of possibility that the author of the prologue to the Fourth Gospel was considerably influenced by this description of wisdom rather than by Philo's descriptions of his Logos, even though he substituted the latter term for "wisdom." This advanced thought as to wisdom is not confined to ch. viii., but seems to be more or less presupposed throughout the section. The author's philosophy of life otherwise shows little of a pronouncedly modern character. Righteousness and wickedness are rewarded in this life (*e.g.*, ii. 21); the sacrificial worship is inculcated (ii. 9, iii. 9); the words "law" and "commandment" are used now of the Mosaic system, now of parental injunctions, now of the sage's advice. It is the language and philosophy of life characteristic of Deuteronomy which are most prominent; suffering is divine chastisement administered, however, in love (iii. 12).

Chapters x.–xxii.—The second section illustrates earlier stages in the literary productions and ideals of the exponents of wisdom. Each proverb is confined to two lines, antithetical in form if we except a few in which synonymous parallelism occurs. The utilitarianism of the compiler of this section is often overemphasized: it contains, on the contrary, sentiments which anticipate some of the highest ideals expressed in the New Testament and to which the latter owe their literary form (*e.g.*, x. 12 *cf.* 1 Cor. xiii. 7, 1 Pet. iv. 3, James v. 20; xiv. 31; xvii. 5, *cf.* Matt. xxv. 40, 45; xx. 11, *cf.* Matt. vii. 16; xx. 22, *cf.* Matt. v. 39, Rom. xii. 17, 19, etc.). It reflects, moreover at times the "prophetic" revolt against the hollowness of merely external sacrificial worship (xv. 8, xxi. 3) *cf.* the emphasis on the *national* virtue demanded by Amos (xiv. 34) and on inner purity (xx. 9) and on the omniscience of Jehovah (xv. 3, 11). Thus, in date, the section shows no trace of the developments of religious, theological and philosophical thought for which the latter post-exilic Judaism was responsible; on the other hand, along with much which might be the product of any period, it presupposes, at least in the above respects, the very latest products of pre-exilic piety.

Chapters xxii. (17) to xxiv. (22).—The third section bears the title "words of the wise." Its contents are presented to the reader in a strophic form, forming a miniature discourse, and having four lines to a strophe, as in the newly deciphered Egyptian "Teaching of Amenophis." It is the remarkable similarity of the section to this latter book which has especially concentrated attention upon it since 1924. The similarity between the two continues, with certain exceptions, throughout a considerable portion of the section and creates a problem which is scarcely solved by the theory that both reflect gnomic sayings which were common to all nations of the orient. Indeed so close is the relationship that it is possible to emend with a fair degree of certainty, on the basis of the Egyptian tradition, passages in which the Hebrew text is manifestly corrupt: thus "excellent things" (xxii. 20) without any change in the consonantal text, should be read as "thirty (sayings)," the exact number of the "chapters" into which *The Teaching of Amenophis* is divided. It would appear unlikely that the Egyptian sage borrowed from the Hebrew, and we are therefore compelled to suppose that either a copy of the Egyptian book penetrated into Palestine and its contents *gradually* became "Hebraised," its Egyptian theology *slowly* yielding to that of the Hebrews and proverbs from other sources gradually attaching themselves to it; or a Hebrew sage, visiting or living in Egypt, became acquainted with it, expurgated its Egyptian polytheism and made it acceptable to those who saw in Jehovah the only God who ruled every department of life. Either of these alternatives can best be visualised as happening in pre-exilic rather than late post-exilic days, but to dogmatise as to the exact date, whether the reign of Hezekiah, the early years of the exile or otherwise is to substitute guesswork for reason. An outstanding one among the many sayings common to the Hebrew and Egyptian gnomic writers occurs in the next section (xxiv. 23–34, an appendix to the present one) as well as already in the preceding one (xx. 22): it is the earliest extant form of "the golden rule," later extolled by Hillel and Jesus, which is thus proved to be in its origins Egyptian rather than Hebrew or Jewish.

Chapters xxv.–xxix. (27).—The fifth section, attributed traditionally to Hezekiah's scribes (xxv. 1), contains, like the second section, chiefly short independent proverbial aphorisms; but it has some of two or more verses in length, and advances from the consideration of worldly matters in chs. xxv.–xxvii. to matters of more specifically religious import in chs. xxviii., xxix., where the observance of "the law" in particular is emphasized, and prophecy is specified as a *sine qua non* of popular self-restraint (xxix. 18). In spite of the presence in this section of proverbs which occur elsewhere, it contains several of considerable interest. It reflects a somewhat hostile attitude to the monarchical form of government, but attempts to deflect criticism from the person of the king to his courtiers. Whether "the king" is a native Jewish ruler, Davidic or Maccabaean, or a Ptolemaic or Seleucid overlord, or merely figures impersonally in a set of proverbs of international vogue cannot be decided: consequently it gives no real help in fixing the date of the section. In at least two respects this collection provided the inspiration for practical and ethical advice too often supposed to have originated in Christian circles, namely xxv. 7 which evidently inspired Luke xiv. 8–11, and xxv. 21 which is quoted in Rom. xii. 20.

Chapter xxx. (1–16).—The sixth section has the cryptic and not very convincing title "The words of Agur, the son of Jakeh, of Massa (R. V. mg.)," followed by a line which has defied all efforts to translate it. This, like xxxi. 1, though a frank confession by the Jewish sages that they were prepared to welcome aphorisms of foreign origin, and having done so, openly to ascribe them to a foreign author, really throws no light upon the origins and background of the present section. It would appear to date from a period when problems of theology and philosophy were being discussed *ad nauseam* and to emanate from an author who found little comfort, but much disturbance of faith in speculations of this nature. Consequently confessing his own limitations of intellect (*v.* 2 *seq.*), he plaintively asks who in point of fact has ever penetrated into the supra-mundane sphere to return with a knowledge adequate to justify him in propounding such riddles (*v.* 4). And so he takes refuge in the revealed "word" of God and utters a warning against human endeavours to supplement it or detract from it in self-confidence or insolence. He ends by pointing out the shortcomings of his generation (*vv.* 5–14). It is the answer of a religious obscurantist rather than, as is too commonly supposed, of a pious agnostic.

Final Section.—The seventh section, chap. xxx. 15–33, consists of miscellaneous *dicta* introduced by an unintelligible line and bound together by their "numerical" form of introduction. In these few words is concentrated a wealth of insight into the normal and abnormal, the obvious and mysterious in life and nature, which, as it were in a nut-shell, illustrates the keenness and the breadth of observation to which the "wisdom" writers, the humanists of Israel, trained themselves.

The eighth section, chap. xxxi. 1–9, purports to be a further instance of foreign wisdom, again from "Massa," and indeed an illustration of a king's instruction by his mother. The vices against which he is warned include impurity, drink and maladministration of justice. These vices were prevalent in most oriental courts of the period during which the section could have been written, and do not necessarily presuppose the vices which Hellenism in particular communicated to the petty kings of oriental states into which it penetrated.

The ninth and last section, chap. xxxi. 10–31, is perhaps the masterpiece of this remarkable collection of the literary output of the humanists of Israel. Incidentally it is an "alphabetical" poem, each verse beginning with a letter of the Hebrew alphabet, and each letter appearing in its correct sequence. The lie is here given to the depressing picture, though one too often fully justified, which is mostly drawn in the Old Testament, of woman's personal and economic position among the Hebrews as the slave and chattel of her husband who was legally free to possess not one but many wives. But practice reinforced by economic necessity, probably rose in this respect above precept. At any rate, in the wealthy and prosperous household here depicted monogamy is presupposed and the poet depicts the wife as its master-mind as well as its mainstay. To what extent such a régime pressed heavily on the female slaves and other underlings we do not know since no litera-

ture emanating from them has survived.

Next to their passion for the highest morality of their day, and their unswerving loyalty to their ancestral faith, certain of the Hebrew gnomic writers whose work has survived in the Book of Proverbs will be held in honour most of all for their ability, which, as stated at the outset, is only now beginning to be realized, to master the gnomic literature of Egypt and of Mesopotamia, of Edom and of Massa, to expurgate from it what was unworthy, and to transform it into an instrument for the instruction of successive generations of the worshippers of Jehovah. Only a study of the Book of Proverbs in the light of the comparative study of gnomic literature can make the reader realize this; for instance in addition to close relationship with the Egyptian *Teaching of Amenophis,* there are more than 70 dicta in the Wisdom of Aḥikar and of these more than half find an echo in this book.

BIBLIOGRAPHY.—For the literature, which is considerable, *see* the commentaries of Toy (1898), and especially W. O. E. Oesterley, *The Book of Proverbs* (1928) in the *Westminster Commentaries,* who gives striking parallels and references to the latest literature. *See* also Cheyne, *Job and Solomon* (1887); id., in *Sem. Studies* (ed. Kohut, 1897); id., *Jew. Relig. Life* (1898); Montefiore in *Jew. Quart. Review* (1898–1890); Cohen, *Ancient Jewish Proverbs;* Elmslie, *Studies in Life from Jewish Proverbs;* Goldman, *Proverbs of the Sages* (1911). PROVIDENCE, the capital and largest city of Rhode Island, U.S.A., a port of entry and the county seat of Providence county; at the head of Providence river (the north arm of Narragansett bay), 27 mi. from the Atlantic ocean, 45 mi. S.S.W. of Boston and 185 mi. E.N.E. of New York city. It is on federal highways 1, 6 and 44; and is served by the New York, New Haven and Hartford railroad and four steamship lines. There are several private airports in and near the city and state airports at Block Island, Hillsgrove, Lincoln and Westerly.

The population was 247,700 in 1950; in 1940 it was 253,504 by the federal census.

The city has a land area of 18.91 sq.mi., diversified in natural character and irregularly laid out. The Seekonk and the Providence rivers bound it on the east; the Providence and the Moshassuck divide it into east and west sides; and the Woonasquatucket divides the west side into north and south sections. The east side (the part of most historic interest) embraces hills rising to a height of 200 feet. The newer business district lies along the west bank of the Providence river, and some of the largest buildings stand on made land. Most of the factories are on the banks of the Woonasquatucket and the Moshassuck. The names of the older streets (such as Benevolent, Benefit, Hope, Friendship, Peace, Pound, Sovereign, Shilling, Dollar and Doubloon) recall the religious spirit of the early city and its commercial character. From the Union station one steps directly into the civic centre, a broad open plaza surrounded by government (Federal, city and county) and business buildings and hotels. Aloof on a hill to the west, but only half a mile distant, the most conspicuous feature of the landscape and commanding a wide view of city, bay and surrounding country, is the large State house (designed by McKim, Meade and White and completed in 1902) of Georgia marble and white granite, surmounted by a marble dome 235 ft. high. In it is a full length portrait of Washington, by Gilbert Stuart (who was born in Rhode Island), and many other interesting paintings, and here is preserved the original charter of the Colony, framed in wood from the "Gaspee." Adjacent to the civic centre on the east is the retail shopping and business district, where tall modern structures of steel and stone rise above the older buildings. An interesting building is the Arcade (1828) with six massive Ionic columns at each entrance.

The old Market house was built in 1773 and in it a local "tea-party" was held on March 1, 1775, and Rochambeau's troops were quartered later.

Behind the business area College hill rises steeply, covered with historic landmarks. On its slopes lies the campus of Brown university (*q.v.*), where Revolutionary troops were quartered in university hall. At its foot stands the First Baptist meetinghouse (built in 1775 to house the church organized by Roger Williams in 1636), which has one of the finest church spires in America, and a beautiful interior, with a crystal chandelier in use since 1792. Its bell still rings the curfew at nine o'clock. Near by is the old Colony house, where the Rhode Island Declaration of Independence was signed on May 4, 1776, two months before the event in Philadelphia. Farther up the hill are the museum and library of the Rhode Island Historical Society, the ivy-covered Athenaeum, and Pendleton house (a museum), furnished with one of the finest collections of early American furniture in existence. Among the old mansions still standing are the homes of John Brown (built in 1786), Thomas Poynton Ives (1806), Col. Joseph Nightingale (1791), Joseph Russell (1772), Peter Randell (1748), Stephen Hopkins (1742) and that of Esek Hopkins (1718–1802), commander of the American navy during the Revolution, standing in a park formed from his estate. The Providence Art club occupies the homes of Nicholas Brown (1787) and Siril Dodge (1793). Many more modest colonial houses (usually of red brick with white marble trimmings, and occasionally set in a walled garden) add to the charm of this section of the city. The Friends' meeting house was erected in 1759. The first Unitarian church (organized 1773) has a bell cast by Paul Revere and his son. The city's parks and playgrounds cover 790 ac., and there are also large reservations under the control of the State. Chief among the municipal parks is Roger Williams park (451 ac.), part of the original tract ceded to Williams by Miantonomo, in which is the cottage (1775) of Betsy Williams, a lineal descendant. The North burial ground contains the graves of many men of prominence in the early history of the State and the nation.

In addition to Brown university, Providence has within its limits the Rhode Island college of education (1854); the Rhode Island school of design, affiliated with Brown (1876); Providence college (Roman Catholic; 1919); the Rhode Island institute for the deaf (1876); and several private secondary schools of high standing. The public-school system has profited in various ways by the presence of Brown university, and has been a pioneer in such educational schemes as transition classes between kindergarten and primary grades and open-air classes for delicate children. There are two daily newspapers. The *Journal* (Independent) was established in 1829. Among the numerous charitable institutions are the Butler Hospital for the Insane, one of the oldest institutions of its kind in the country (established by a bequest of Nicholas Brown in 1841), and the Dexter Asylum for the Poor, endowed by the Dexter fund, which limits its beneficiaries to those who have a legal settlement in Providence (*i.e.,* have paid taxes for five years on $200 worth of property) and consequently is very restricted in its application. The privately supported welfare agencies and philanthropic organizations unite in a joint annual campaign for funds.

Providence river and harbour have been under improvement by the United States since 1852. The channel to the ocean is 35 ft. deep at mean low water and from 600 to 1,800 ft. wide. A state pier (built in 1913) and a municipal wharf provide modern terminal facilities for the public on equal terms, and there are 5 wharves owned by steamship lines, 10 by the railroad and 43 by other private interests. Providence is the principal port of southern New England. Its water-borne commerce averaged 4,949,060 tons annually for the years 1940–47, and in 1947 amounted to 6,436,224 tons. The great bulk of the domestic commerce consists of incoming coal, lumber, crude and fuel oil and petroleum products.

Providence is one of the leading centres of the country for the manufacture of jewellery, silverware, worsteds, textile machinery and tools.

Its aggregate factory output in 1947 was valued at $262,822,000, of which $50,806,000 represented worsteds and $39,159,000 jewellery. Among the long-established firms of national reputation are the Gorham Manufacturing company, which introduced the jewellery and silverware industry, the Brown and Sharpe

Manufacturing company and the Nicholson File company. The famous Corliss engines were first made in Providence in 1847.

The city operates under the original charter of 1832, with various amendments, providing for a mayor and council form of government.

The franchise is limited to persons who pay a tax on $134 worth of real property or $200 worth of personal property. A town meeting is still held annually for the administration of the Dexter fund.

The levy of general property taxes in 1950 was $17,399,714. Bank debits in 1949 aggregated $3,840,608,000.

Providence was founded in 1636 by Roger Williams after his banishment from the Massachusetts Bay Colony. He bought a tract of land from the Narragansett sachems Canonicus and Miantonomo, built a house opposite the confluence of the Moshassuck and the Woonasquatucket rivers (50 ft. east of North Main street), and with a few followers who had accompanied him into exile promptly set up a town government. In 1637, after the arrival of a few more settlers, a plantation covenant was adopted, embodying the novel principle of complete separation of religious and civil affairs. Providence was incorporated as a town by the colonial assembly in 1649, and was chartered as a city in 1832. The name was chosen by Roger Williams in recognition (he says) of "God's merciful providence unto me in my distress." Between 1730 and 1760 its area was reduced from 370 sq.mi. to 5.5 sq.mi. by the setting off of Scituate, Gloucester, Smithfield, Cranston, Johnston and North Providence, some of which were further subdivided subsequently; and since 1860 the 5.5 sq.mi. have been increased to over 18 by re-annexations of contiguous territory. During King Philip's War, in 1676, the town was attacked by Indians and the northern half was burned. In June 1772, a British schooner, the "Gaspee," running aground at what has since been known as Gaspee point, was captured and burned by Abraham Whipple (1733–1819) according to a plan devised by John Brown (1736–1828), one of the town's prominent merchants. During the Revolution, Providence was a centre of privateering, and in consequence of the occupation of Newport by the British took over much of the foreign commerce of that port. It remained an important port for 40 or 50 years, but after 1830 manufactures became the dominating interest. Since 1900 its water-borne commerce has again increased, more than doubling in volume in the first quarter of the century. Providence shared with Newport the honour of being the seat of the State government until 1900; since 1900 it has been the sole capital.

PROVINCE, a term applied in ancient Rome (Lat. *provincia*) to the sphere of duty assigned to one of the higher magistrates, the consuls and praetors (*qq.v.*). Only those magistrates who had military power (*imperium*) had a province. When the province of a quaestor is mentioned it refers to the province of the consul or praetor to whom the quaestor is subordinate.

When the government of conquered countries grew to be one of the most important duties of the higher magistrates, the term province, from designating the government of a conquered country as one particular duty of a Roman magistrate, came to be used generally as a designation of the country itself.

The provinces paid tribute to Rome, for it was a recognized principle that they were the estates of the Roman people and were to be managed for its benefit. The constitution of a province was drawn up by the victorious Roman general, assisted by ten commissioners appointed by the senate, and the province was governed on the lines laid down in this constitution or charter (*lex provinciae*). For administrative purposes the province was divided into districts, each with its capital, for judicial purposes into circuits (*conventus*) and in the chief town of each circuit the governor of the province held assizes.

The lands of cities captured by force of arms were turned into Roman domains, and were let out by the censors to private persons. Royal domains, such as those of Macedonia and Cyrene, were also confiscated. Communities which surrendered were usually allowed to retain their personal freedom and private property; but all the lands were subjected to a tax, consisting either of a payment in kind (*vectigal*) or of a fixed sum of money (*tributum, stipendium*). It is to this class of communities (the *civitates vectigales* or *stipendiariae*) that the majority of the provincial states belonged. In a better position were those states whose freedom was guaranteed by Rome on the ground of old alliances or special loyalty. Their freedom was recognized either by a treaty or by a decree of the Roman people or senate. As a decree of the people or senate could at any time be recalled, the position of the free states without a treaty was more precarious than that of the treaty states (*civitates foederatae*). The latter enjoyed internal freedom, retained their lands, paid no taxes, and were bound to render those services only which were expressly stipulated for in the original treaty. Amongst such treaty states were Massilia (Marseille), Athens, Rhodes and Tyre. The privileges of the free states without a treaty were somewhat similar. All political distinctions, save that between slave and freeman, disappeared when Caracalla bestowed the Roman franchise on the whole empire (A.D. 212).

Provincial Diets.—Every province had, under the empire, a provincial assembly or diet of its own (*concilium* or *commune*), and these diets are interesting as the first attempts at representative assemblies. The diet met annually, and was composed of deputies (*legati*), from the provincial districts. It arranged for the celebration of religious rites and games, especially for the worship of the emperor. The celebration was under the conduct of the high priest of the province. The diet also passed votes of thanks to the outgoing governor, or forwarded complaints against him to Rome; and it had the right of sending embassies direct to the senate or the emperor.

The Provincial Governor.—The provinces were administered by governors from Rome, who held office for a year. From the formation of the first provinces in 227 B.C. down to the time of Sulla (82 B.C.) the governors were praetors (*see* PRAETOR); from the time of Sulla to that of Augustus the praetors remained in Rome during their year of office, and at the end of it assumed the government of a province with the title of propraetor. A province which was the seat of war, or was in a disturbed state, was committed to the care either of one of the consuls for the year, or of a commander specially appointed for the purpose, with the title of proconsul. The senate determined which provinces were to be governed by consuls and which by praetors, and the consuls arranged between themselves which of the provinces each should have, and similarly with the praetors. The Sempronian law of 123 B.C. provided that the senate should nominate the two consular provinces before the election of the consuls, and that the consuls should, before their entry on office, arrange which of the two provinces each should have. The Pompeian law of 53 B.C. enacted that no one should hold the governorship of a province till at least five years after his consulship or praetorship. This law was repealed by Caesar, but was re-enacted under Augustus; it severed the connection between an urban magistracy and the governorship of a province, and turned the latter into an independent office. A provincial governorship was regularly held for one year; but it could be prolonged by a vote of the people or a decree of the senate. The necessary supplies of men and money were voted to the governor by the senate. His staff included one or more lieutenants (*legati*) and a quaestor (*q.v.*). Besides these the governor took with him young men of the upper classes to assist him in the government. These were known as the companions (*comites*) or suite of the governor. They were chosen by the governor himself, but they were maintained at the expense of the state, and under the empire, received regular pay. In addition there was a crowd of subordinates. Before setting out for his province the governor, clad in the purple military robe of his office, offered sacrifice on the Capitol; then immediately after receiving the *imperium* or military command he marched out of the city (for the *imperium* could only be exercised outside of Rome and was forfeited by staying in the city), preceded by his lictors and accompanied by his suite. His year of office began from the day he set foot in his province. In the hands of the governor all powers military and civil were united. He commanded all the troops in the province, and had power to raise levies of Roman citizens as well as of provincials, and to make

requisitions of war material. He possessed both criminal and civil jurisdiction; as criminal judge he had the power of life and death, and from his sentence none but Roman citizens could appeal; as civil judge he was guided partly by the charter of the province (*lex provinciae*), partly by the edict which it was customary for him to issue before his entrance on office (*see* PRAETOR).

Condition of the Provinces under the Republic.—The Roman people regarded the provinces as so many estates from which they were to derive revenue. Hence agriculture and commerce were encouraged, settlements were made, roads and aqueducts were constructed; in short, the Roman aimed at exploiting his empire by a system of prudent economy. But the Roman governors were apt to look on their provinces as their own peculiar prey; they had usually bought their way to office at vast expense, and they now sought in the provinces the means of reimbursing themselves for the expenditure they had incurred at Rome. Redress was to be had by a complaint to the senate; after 149 B.C. there was a court established at Rome for the trial of cases of extortion (*repetundae*) by provincial governors. But, even when the provincials had arraigned their oppressor, it was difficult to secure his condemnation at the hands of juries composed of men who had a fellow-feeling for the offender because they had themselves committed, or hoped for means of committing, similar offences. Besides the governor, two classes joined in wringing the uttermost farthing from the unhappy provincials. These were the *publicani* (*q.v.*) or farmers of the taxes, and the money-lenders (*negotiatores*). Both these classes were recruited from the *equites* (*q.v.*) and, since from 122 B.C. the juries were drawn at first exclusively and after 70 B.C. partially from that order, the provincial governor could not check their excesses without risking a condemnation at the hands of their brethren. Accordingly he generally made common cause with them.

The Provinces under the Empire.—Under the empire the provinces fared better. Romans and provincials were reduced to a common level of subjection to the emperor, who meted out equal justice. The first centuries of the Christian era were for some of the countries included in the Roman empire the happiest of their history.

Augustus, in 27 B.C., divided the provinces into imperial and senatorial. Those which required the presence of an army were placed under the direct control of the emperor; those which needed no troops were left to the senate. (1) The senatorial provinces were ruled by annual governors called proconsuls. Their powers were much the same as they had been under the republic, except that they had now no troops, or only a handful to maintain order. (2) The imperial provinces were governed by imperial lieutenants (*legati Caesaris*), who were nominated by the emperor and held office at his pleasure; all of them had the power of the sword (*ius gladii*). For the administration of the finances these lieutenants had procurators under them, while the governors of the senatorial provinces continued to have quaestors. Certain other possessions were regarded as domains of the emperor, and were managed by a procurator or praefect (*see* PRAEFECT), responsible to the emperor.

See T. Mommsen, *Roman Provinces under the Empire* (1884); T. M. Taylor, *Constitutional History of Rome* (1899); J. E. Sandys, *Companion to Latin Studies* (1921), with useful bibliography. For imperial domains, *see* H. F. Pelham, *Essays on Roman History* (1911), pp. 275–299.

PROVINCETOWN, a town of Barnstable county, Massachusetts, U.S.A., on the tip of Cape Cod; it is on federal highway 6 and is served by the New York, New Haven and Hartford railroad, and steamboats to Boston; there is an airport. Population was 3,736 in 1950; 3,668 in 1940. There are many visitors in summer, among whom are a large number of artists, attracted by the beauties of the sand dunes and the marine views. The town is almost surrounded by water, and there are three lighthouses on its coast. Its harbour (to the south) is protected on three sides by land. A magnificent beach stretches for 30 mi. along Cape Cod bay to Eastham. Provincetown is a port of entry. The principal industries still (as since its settlement) are the catching, curing, packing and selling of fish, chiefly cod and mackerel. The large whaling fleet of former days has entirely disappeared. It was in Provincetown harbour that the Pilgrims, in the cabin of the "Mayflower," drew up their memorable Compact, before proceeding to Plymouth. There John Carver was chosen as the first governor of Plymouth Colony, and this was the first landing-place (on Nov. 11 [O.S.], 1620) of the Pilgrims in the New World. There has been a settlement there since 1620. The town was set off from Truro and incorporated in 1727. Much of the territory was originally "Province land" (hence the name) and there is still a large State reservation between the village and the back ocean shore, which has been stocked with game birds and planted with beach grass and pine trees.

PROVINS, a town of northern France, capital of an arrondissement of the department of Seine-et-Marne, at the junction of the Durtain with the Voulzie (an affluent of the Seine), 59 mi. E.S.E. of Paris by rail. Pop. (1946) 8,840. Provins began to figure in history in the 9th century. Passing from the counts of Vermandois to the counts of Champagne, it quickly became prosperous. Cloth and leather were its staple manufactures, and its fairs were attended by traders from all parts of Europe, throughout which its money had currency. Plague and famine reduced the population in the 14th century and the Hundred Years' War completed its ruin. During the religious wars it sided with the Catholic party and the League, and Henry IV obtained possession of it in 1592 only after thirteen days' siege. The town has mineral waters which contain iron, lime and carbonic acid, and also a trade in roses. Provins is divided into two quarters—the *ville-haute* and the less ancient *ville-basse*—which in the 13th century were surrounded by fortifications. In the *ville-haute* stands the large tower known as the king's, Caesar's or the prisoners' tower, a very curious 12th century keep. The base is surrounded by a thick mound of masonry added by the English in the 15th century when they held the town. The tower serves as belfry to the church of St. Quiriace, which dates from the 12th century. The palace of the counts of Champagne, some fragments of which also belong to the 12th century, is occupied by the communal college. The old tithe-barn is a building of the 13th century with two fine vaulted chambers, one of which is below ground. The church of St. Ayoul dates from the 12th to the 16th centuries, the transept being oldest; it is dilapidated and the choir is used as a storehouse. St. Croix belongs partly to the 13th century. There is a subprefecture and a tribunal of commerce. There is an active trade in grain, livestock and wool, and the industries include nursery-gardening, brickmaking and the manufacture of porcelain, gas and petrol engines, agricultural implements and sugar.

PROVISION, in ecclesiastical law signifies the act by which an office or benefice is conferred by a person having competent authority for the purpose; and the word is specially used of appointments made by the pope in derogation of the rights of ecclesiastical patrons. Innocent III (1198–1216) seems to have been the first pope who directed prelates to collate his nominees to canonries and other benefices, but it was during the pontificate of Innocent IV (1243–1254) that the practice first assumed alarming proportions. The English parliament held at Carlisle in 1307 petitioned the king for a remedy against this abuse, but though he promised redress nothing was done. Meanwhile the popes had been asserting claims to appoint bishops in certain events on their own initiative, and at last Clement V (1305–1313) reserved to himself the right of appointment in all cases. After his time there is scarcely an instance of an English bishop being elected in accordance with the older procedure by the cathedral chapter. If an election were made the pope usually either overrode it by another appointment or, ignoring the election, appointed the elected clerk by a bull of provision. The Hundred Years' War caused an outburst of indignation against the use of papal provisions when non-resident French clerics were appointed to English benefices. To remedy the evil the first "Statute of Provisors" was enacted in 1351, the "Statute of Praemunire" in 1353, and a second "Statute of Provisors" in 1364. These appear to have had little effect until in 1389, a third "Statute of Provisors" was enacted which provided that the statute of 1351 should be firmly holden for ever and "put in due execution from time to time in all manner of points."

PROVISIONAL ORDER, in Great Britain, a direction by a government department sanctioning (usually at the instance of a local authority or public undertaking) some project otherwise unattainable without private bill legislation, *e.g.*, the compulsory taking of land or the building of a tramway. Originally the order is provisional because subject to parliamentary veto. The objects depend upon the enabling statute.

The procedure generally involves: (1) preliminary local enquiry and report by a departmental inspector; (2) departmental decision as to the framing of the order; and (3) inclusion of the order (singly or grouped with others) in a provisional order confirmation bill introduced into parliament by the minister concerned. Such bills, if opposed, are referred to a select committee; they also go before examiners who see that the contents comply with standing orders. An early instance is the Inclosures Act of 1845 whereby commissioners could provisionally order the enclosure and regulation of commons. In 1853 the charity commissioners were authorized to give provisional approval to new schemes for the application and management of charities. Gradually the system was extended to the varied purposes of local government (especially the alteration of areas), public health, gas, water and electricity supply, acquisition of school and housing sites, formation of pilotage and drainage districts, facilities for harbours, docks, railways and other forms of transport, fishery regulation, validation of marriages, etc. The early enactments were later superseded and the process of devolution progressively developed. Two railway acts in 1864 initiated the provisional certificate which embodied schemes for railway construction or working agreements, and, unless the schemes were opposed, required no express parliamentary sanction. A further delegation of legislative power enabled a local authority to make orders for the acquisition of land (as under section 9 of the Local Government act, 1894). If not objected to, they had the full force of a statute; if objected to, they could be confirmed not by parliament but by the department concerned. Later a special order procedure was evolved whereby a draft of the proposed order was published and (on objection) a local enquiry was held, but a confirmatory act of parliament was not required. The National Health Insurance Act of 1928 authorized a "provisional special order." Under this variant (invented in 1912 to accelerate the action of special orders under the 1911 act) the appropriate minister, instead of waiting for criticisms of his draft orders, could bring them into force forthwith provided that he certified the expediency of such action. Some special orders, such as those which decided the application of unemployment insurance or trade boards legislation to particular trades, took effect forthwith, subject to annulment on adverse resolution by either house of parliament within a time limit; others, *e.g.*, those under the Electricity (Supply) Act of 1919 or the Gas Regulation Act of 1920, required the affirmative resolution of both houses. Special orders were often allowed to do all that a provisional order could formerly do. Scotland developed its own method under the Private Legislation (Procedure) Scotland act, 1899, operated through the Scottish Office, with special panels of commissioners for holding enquiries. Northern Ireland followed the Westminster model.

See Clifford, *Private Bill Legislation,* ii, c. 18. (C. T. C.)

PROVO, a city of Utah, U.S., on the Provo river, 3 mi. E. of Utah lake and 45 mi. S. of Salt Lake City; the county seat of Utah county. It is on federal highways 91, 89 and 50, and is served by the Denver and Rio Grande Western, the Union Pacific and the Utah (for freight only) railways. Pop. (1950) 28,937; (1940) 18,071 by the federal census. The city has an altitude of 4,549 ft., in a region of fine scenery. It is the seat of Utah State (mental) hospital and Brigham Young university (founded and endowed by President Young in 1875), with an enrolment of 6,000. Provo is a "garden city," surrounded by the richest agricultural and horticultural district of Utah, created by irrigation and industry out of the desert. It is an important industrial centre; near by is the Geneva Steel plant built during World War II at a cost of $200,000,000; there are also factories making cast-iron pipe, foundry products, steel tanks, creosoting materials, brick and tile, concrete pipe, etc. Provo was named for Etienne Provot, a French-Canadian trapper who explored the area in 1825; it was settled by the Mormons in 1849 and was chartered in 1851. It has a commission form of government.

PROVOST, a title attached to various ecclesiastical and secular offices. In ecclesiastical usage the word *praepositus* was at first applied by the church fathers to any ecclesiastical ruler or dignitary. It early, however, gained a more specific sense as applied to the official next in dignity to the abbot of a monastery, or to the superior of a single cell. In England the title provost has thus everywhere given way to that of "dean"; in Germany, on the other hand, "*Probst*" is still the style of the heads of certain chapters. The name *praepositus* was also sometimes used for the secular *advocatus* of a monastery. With the ecclesiastical use of the title is connected its English application to the heads of certain colleges; "provost" is still the style of the principals of Queen's, Oriel and Worcester colleges at Oxford, of King's college at Cambridge, of Trinity college at Dublin and of Eton college, where, however, the headmaster, though technically subordinate to the provost, is the effective head of the school.

As a secular title *praepositus* is also very old; we need only instance the *praepositus sacri cubiculi* of the late Roman empire, and the *praepositus palatii* of the Carolingian court. The important developments of the title in France are dealt with below. From France the title found its way into Scotland, where it survives in the style (provost) of the principal magistrates of the royal boroughs ("lord provost" in Edinburgh, Glasgow, Aberdeen, Perth and Dundee), and into England, where it is applied to certain officers charged with the maintenance of military discipline. A provost marshal is an officer of the army appointed when troops are on service abroad for the prompt repression of all offences. He may at any time arrest and detain for trial persons subject to military law committing offences, and may also carry into execution any punishments to be inflicted in pursuance of a court-martial (Army act, 1881, *s.* 74). A provost sergeant is an officer responsible for the maintenance of order when soldiers are in Great Britain. A provost sergeant may be either garrison or regimental, and he has under his superintendence the garrison or regimental police.

The Provost in France.—The word *prévôt* (provost) in old French law had many applications. In conformity with its etymology (*praepositus*) it could be applied to any person placed at the head of a branch of the public service, a position which, according to the old principles, habitually carried with it a right of jurisdiction. It is thus that there was at Paris the provost of Paris, who was a royal judge, and the provost of the merchants (*prévôt des marchands*), the head of the Paris municipality. There were besides—to mention only the principal provosts—the provosts of the marshals of France (*prévôts des maréchaux de France*), of whom more below; the provost of the royal palace (*prévôt de l'hôtel du roi*) or grand provost of France (*grand prévôt de France*), and the provost general (*prévôt général*) or grand provost of the mint (*grand prévôt des monnaies*). But the most important and best known provosts, who formed part of a general and comprehensive organization, were the royal provosts (*prévôts royaux*), the lower category of the royal judges. It must be borne in mind, however, that the magistrates belonging to the inferior category of royal judges (*juges subalternes*) had different designations in many parts of France. In Normandy and Burgundy they were called *châtelains,* and elsewhere—especially in the south—*viguiers.*

Some time in the 11th century the provosts replaced the viscounts wherever the viscounty had not become a fief, and it is possible that in creating them the crown was imitating the ecclesiastical organization in which the provost figured, notably in the chapters. The royal provosts had at first a double character. In the first place they fulfilled all the functions which answered locally to the royal power. They collected all the revenues of the domain and all the taxes and dues payable to the king within the

limits of their jurisdiction. Doubtless, too, they had certain military functions, being charged with the duty of calling out certain contingents for the royal service; there survived until the end of the *ancien régime* certain military provosts *prévôts d'épée* (provosts of the sword) who were replaced in the administration of justice by a lieutenant. Finally, the provosts administered justice, though certainly their competence in this matter was restricted. Their second characteristic was that their office was farmed for a time to the highest bidder. It was simply an application of the system of farming the taxes. The provost thus received the speculative right to collect the revenues of the royal domain in the district under his jurisdiction; this was his principal concern, and his judicial functions were merely accessory. By these short appointments the Crown guaranteed itself against another danger: the possible conversion by the functionary of the function into a property. Very early, however, certain provostships were bestowed *en garde; i.e.*, the provost had to account to the king for all he collected. The *prévôtés en ferme* were naturally a source of abuses and oppression, the former seeking to make the most of the concession he had bought. They disappeared in the 16th century, by which time the provosts became regular officials, their office being purchasable.

Other transformations had previously taken place. The creation of the royal *baillis* reduced the provosts to a subaltern rank. Each *bailli* had in his district a certain number of provosts, who became his inferiors in the official hierarchy. When appeals were instituted (and this was one of the earliest instances of their introduction) the provost, the sphere of whose competency was limited, was subject to an appeal to the *bailli*, though his judgment had hitherto been without appeal. Moreover, in the 14th century they had ceased to collect the revenues of the royal domain, except where the *prévôté* was *en ferme*, and royal collectors (*receveurs royaux*) had been appointed for this purpose. The summoning of the feudal contingents, the *ban* and *arrière-ban*, had passed into the hands of the *baillis*. Thus the provosts were left for their sole function as inferior judges for non-nobles. (*See* BAILIFF AND BAILIE.)

The "provosts of the marshals of France," mentioned above, were non-legal officials (*officiers de la robe courte*) forming part of the body of the *maréchaussée* which was under the *ancien régime* what the *gendarmerie* was after the Revolution. Their original function was to judge offences committed by persons following the army, but in the course of the 14th and 15th centuries they acquired the right of judging certain crimes and misdemeanours, by whomsoever committed. They became stationary, with fixed spheres of authority, and the offences falling within their competency came to be called *cas prévôtaux*. These were the worst crimes of violence, and all crimes and misdemeanours committed by old offenders (*repris de justice*), who were familiarly known as the *gibier des prévôts des maréchaux* (gaol-birds).

(J. P. E.)

PROXY (short for "procuracy"), a term denoting either (1) a person who is authorized to stand in place of another; (2) the legal instrument by which the authority is conferred. Proxies are now principally employed for certain voting purposes. A proxy may in law be either general or special. A general proxy authorizes the person to whom it is entrusted to exercise a general discretion throughout the matter in hand, while a special proxy limits the authority to some special proposal or resolution. Formerly a peer could give his vote in the British parliament by proxy, by getting another peer to vote for him in his absence, temporal peers only voting for temporal and spiritual peers for spiritual. However, on March 31, 1868, on the recommendation of a committee, a new standing order was adopted by which the practice of calling for proxies on a division was discontinued. In English and American bankruptcy proceedings creditors may vote by proxy, and every instrument of proxy, which may be either general or special, is issued either by the official receiver or trustee. Under the English Bankruptcy Act of 1914 and the American Bankruptcy Act of 1898 a creditor may still vote by proxy in the manner prescribed. A shareholder in a limited liability company may vote by proxy, and regulations to that effect prescribing the requirements are usually embodied in the articles of association. In England a proxy to vote at a meeting must bear a revenue stamp. (*See* PROCURATION.)

In the early practice of the admiralty courts a proxy was the authority by which the proctor or advocate appeared for either party to a suit. In the ecclesiastical courts a proxy is the warrant empowering a proctor to act for the party to a suit. Two proxies are usually executed, one authorizing the proctor to institute, the other to withdraw, proceedings. They are signed by the parties, attested by two witnesses, and deposited in the registry of the court (Phillimore, *Ecclesiastical Law*). In the convocations of the Church of England those who are absent are allowed to vote by proxy. (*See* also PROCURATION.) Marriage by proxy or deputy was a custom recognized either for reasons of State or ceremonial. The extension of the doctrine to ordinary marriages was recognized in a few wartime cases in the United States.

PRUDENTIUS, AURELIUS CLEMENS (348–*c.* 410), the most remarkable of the earlier Christian poets in the West, was probably born at Tarraco. The meagre autobiographical preface, which he affixed to the complete edition of his works when he was fifty-seven years old, makes it clear that he received a liberal education—being of noble family—practised as a lawyer and entered official life, and finally held some high office under Theodosius. At the age of fifty-seven he retired to a monastery, but died shortly afterwards.

Bentley calls Prudentius "the Horace and Virgil of the Christians," but his diction is stilted and his metre often faulty. The list of his works given in the preface mentions the hymns, poems against the Priscillianists and against Symmachus and *Peristephanon*. The *Diptychon* or *Dittochaeon* is not mentioned. The twelve hymns of the *Cathemerinon liber* ("Daily Round") consist of six for daily use, five for festivals, and one intended for every hour of the day. Prudentius shows Ambrose as his master here, but gives to Ambrose's mystic symbolism much clearer expression. The *Apotheosis* and *Hamartigenia* are polemic, the first against the disclaimers of the divinity of Christ, the latter against the gnostic dualism of Marcion and his followers. In them Tertullian is the source of inspiration. Of more historical interest are the two books *Contra Symmachum*, of 658 and 1,131 hexameter verses respectively, the first attacking the pagan gods, the second directed against the petition of Symmachus to the emperor for the restoration of the statue of Victory which Gratian had cast down.

The *Peristephanon* consists of fourteen hymns to martyrs. These were mostly Spanish, but some were suggested to Prudentius by sacred images in churches or by the inscriptions of Damasus. This book, with the *Cathemerinon liber* and the *Psychomachia*, was among the most widely read books of the middle ages. Its influence on the iconography of mediaeval art was great. The *Psychomachia* is aesthetically inferior, but had the greatest influence of all of Prudentius's writings. In it he depicts the struggle of Christendom with paganism under the allegory of a struggle between the Christian virtues and the pagan vices. The *Dittochaeon* is a series of quatrains, probably intended to explain forty-nine pictures of a basilica. The work is more interesting for archaeology than for literature.

Prudentius's works were published by Giselin at Antwerp in 1564, and by F. Arevalo at Rome in 1788, with complete commentary. This last is the edition reprinted in J. P. Migne's *Patrologia Latina*, vols. lix.–lx. (Paris, 1847). More recent editions are by Obbarius (Tübingen, 1845) and A. Dressel (Leipzig, 1886), while a critical edition has been undertaken by J. Bergmann.

PRUD'HON, PIERRE (1758–1823), French painter, born at Cluny on April 4, 1758, was the thirteenth child of a mason.

The monks of the abbey undertook his education, and by the aid of the bishop of Mâcon he was placed with Devosge, director of the art school at Dijon. In 1778 Prud'hon went to Paris armed with a letter to Willie, the celebrated engraver, and three years later he obtained the triennial prize of the states of Burgundy, which enabled him to go to Rome, where he became intimate with Canova. He studied the work of Correggio and the affinity of his style with that of the great Italian has given him the name of "Corrège Français." He returned to Paris in 1787. The illustrations which he executed for the *Daphnis and Chloe* published by Didot brought him into notice, and his reputation was extended by the success of his decorations in the Hôtel de Landry (now Rothschild), his ceiling painting of "Truth and Wisdom" for Versailles (Louvre), and of "Diana and Jupiter" for the Gallery of Antiquities in the Louvre. In 1808 he exhibited "Crime pursued by Vengeance and Justice" (Louvre), which had been commissioned for the assize courts, and "Psyche carried off by Zephyrs." These two compositions brought Prud'hon the Legion of Honour; and in 1816 he entered the Institute. Consoled for the misery of his marriage by the devoted care of his pupil, Mlle. Mayer, Prud'hon's situation seemed enviable; but Mlle. Mayer's tragical suicide in 1821 brought ruin to his home, and Prud'hon died two years later on Feb. 16, 1823.

PRUNE: *see* PLUM.

PRUNELLA, a term obtained from the French *Prunelle,* and applied to worsted or woollen twill fabrics of light but strong texture, produced with the three-end $\left(\frac{2}{1}\right)$ warp-face twill weave and usually woven from hank-dyed yarn of a dark purple colour both for warp and weft, or else piece-dyed in the same colour and formerly much used for clerical garments. It is now made in various grades of texture both plain and striped and used as dress material, ladies' sport skirts, and other articles of clothing both for men and women. A stronger and heavier texture of prunella cloth of a similar character to "everlasting," is also produced from a worsted warp and cotton weft and woven with the double-stitch five-end warp-face satin weave, and used for ladies' shoe-tops. The three-end warp-face twill weave is also described as the "prunella" twill, irrespective of the class of fabric to which it is applied. (H. N.)

PRURITUS (itching) is a sympton of many skin conditions, particularly dermatitis and eczema, insect bites, hives, scabies and pediculosis (lice), prickly heat and some superficial fungous infections. It may be almost entirely psychic in origin (localized neurodermatitis), and in generalized form is sometimes a symptom of internal diseases such as jaundice, diabetes and leukemia. Pruritus is probably a modified form of pain. Symptomatic treatment is unsatisfactory; relief of the underlying cause is essential. Aspirin is sometimes helpful. Excessive bathing should be avoided. The application of complex chemicals to the skin in an effort to control itching, may be productive of allergic reactions.

(D. M. P.)

PRUSSIA, a former German kingdom, became the largest and most important *Land* of the Third German Reich. It included the whole of Germany north of Saxony, Thuringia, Bavaria and Hesse, except Mecklenburg and Oldenburg, and some small enclaves, such as Brunswick. In 1938 the *Land* of Prussia comprised the provinces of East Prussia, Berlin, Brandenburg, Pomerania, Grenzmark, Silesia, province of Saxony, Schleswig-Holstein, Hanover, Westphalia, Hesse-Nassau, Rhine province and Hohenzollern. In 1945 East Prussia passed in part to the U.S.S.R. and the remainder to Poland. Poland also absorbed all Prussian territory as far as the Oder-Neisse line, expelling the German population and replacing it by Poles. The main part of the rest of Prussia was subdivided into the new *Länder* of Brandenburg and Saxony-Anhalt in eastern Germany, and Schleswig-Holstein, Lower Saxony and North Rhine-Westphalia in western Germany. Berlin was divided between the two republics. Lesser areas of Prussia were included in the *Länder* of Mecklenburg in eastern Germany, and of the Rhineland-Palatinate, Hesse and Baden-Württemberg in western Germany. Though the boundaries of the new *Länder* usually followed the former political pattern, some regard was also paid to their economic character. Prussia was formally liquidated by a law of the Allied Control council on Feb. 25, 1947.

Physical Features.—The greater part of Prussia belongs to the Great European plain, though its surface is more varied than that bare statement suggests. The plain is narrowest in the west, being only 75 mi. wide between the Weser uplands and the North sea. It includes three divisions, markedly different in character: (1) west of the lower Elbe, a region of reclaimed *Märschen* along the coast, of *Moor* or ill-drained peat bogland behind it, and of dry, sandy *Geest* lands further inland; (2) east of the Elbe, with the low Baltic heights next the coast and the belt of *Urstromtäler,* wide marshy valleys, to the south; (3) the fertile *Börde* strip along the edge of the uplands and with wide "bays" (Cologne, Münster, Leipzig and Silesia) reaching south into the mountainous country. In the southwest, most of the Rhine plateau country, the Harz and Weser uplands and part of the Triassic hill country (with the volcanic Vogelsberg and Rhön) fall within the Prussian area. The borderlands between Silesia and Czechoslovakia are also mountainous. The lowland courses of all the north German rivers are thus within the Prussian frontiers.

Prussia contains a large proportion of woodland, the most extensive forests being in East Prussia, Silesia and Brandenburg where conifers prevail. In the Rhenish and Hessian lands oaks and beeches are most prominent. The northwestern lowlands had few trees but in recent years large plantings of conifers have been made on the drier sandy lands. The heavy cutting after 1933, when importation of constructional timber was restricted, seriously depleted reserves.

Climate.—As could be expected from its position in the continent, the climate of Prussia is transitional between the rainy and changeable type of western Europe and the more stable but more extreme type of eastern Europe. Winters everywhere are usually cold enough to stop work on the land, west Prussia having one month and east Prussia three months with mean temperatures below freezing. In an average winter snow falls on 34 days in Berlin and the Rhine is ice-bound at Cologne for 21 days. Summers are generally warm (63° to 66° F. in July) and rather rainier than the winters. Rainfall decreases from west to east but temperature ranges increase, mainly because winters are colder.

Area and Population.—In 1939 Prussia had a total area of 117,883 sq.mi. and, according to the census of 1939, a population of 41,762,040. The six new *Länder,* with a total area of 55,814 sq.mi., had in 1939 a population of 28,269,000, increased to 30,766,000 by 1946. World War II and the postwar years saw considerable movements of population throughout the Prussian area. The North Rhine-Westphalian districts continued to have the densest populations (896 per sq.mi. in 1946) but the largest increases were in the eastern sections of west Germany. During the war there was a tendency to place new industrial establishments there rather than in the Rhine districts, where they were more accessible to Allied bombing. The *Auslands-deutsche* recalled between 1939 and 1944 were mainly settled in the eastern portions of Prussia. The still larger migration of about 9,000,000 people expelled from Poland and Czechoslovakia added to this westward movement. After the war the movement was continued by the refugees passing from east to west Germany. Large population increases, especially in rural districts, have been caused in this way, notably in Schleswig-Holstein and Lower Saxony.

Agriculture.—Except in Westphalia and the northern Rhinelands, and along a narrow belt from Münster to Silesia, where there was a slight predominance of industry, agriculture was everywhere the main occupation of the people of Prussia. The chief arable areas were along the Baltic coast and on the loess soils of the *Börde.* In Brandenburg and Lusatia arable land was mixed with woodland, on the geest with sandy waste. The reclaimed marshlands were either under the plow or meadow. Grasslands dominated the area from Schleswig-Holstein to the lower Rhine. Rye was the main grain crop everywhere (about 75% of the grain-growing area), especially prominent between the lower Ems and

the Weser, and in Brandenburg and Posen. Wheat and winter barley were restricted to the better soil areas of the *Börde*, the drained marsh soils of the Elbe and Vistula, and the Lower Rhine. Oats became an important crop on the northwest lowlands, especially near the sea. The potato was widely grown, with heavy production east of Berlin and the middle Elbe. On the Rhenish plateau it took the place of grain as the main food crop. In later years sugar beet had become of very great importance as a crop on the *Börde* in Hanover and Saxony, and west of Cologne. In normal years there were surpluses of rye, oats and sugar.

The production of livestock did not meet the demand before World War II, nor was there a sufficiency of dairy produce. Cattle were most numerous in Schleswig-Holstein, and pigs were raised and fattened in great numbers, particularly on the lowland between Hamburg and the Ruhr. The numbers of sheep showed a long-continued decrease. Stall feeding of cattle was general except on the North sea *Märschen* where all-year outdoor grazing of dairy cattle was possible. Forage crops were widely grown and there was considerable import of animal foodstuffs, though the spread of sugar beet, with the use of the tops and the pulp from the sugar factories, had lessened the need for this. The value of animal products far exceeded that of crops.

Most of the land east of the Elbe and in Silesia was in large holdings of more than 250 ac., that in the western lowlands and the Rhine lands in holdings of 12 to 50 ac. The farms of the *Börde* were of intermediate size. During the nazi period steps were taken to divide some of the larger holdings and to consolidate the smallest. Under Soviet direction all holdings of more than 250 ac. were to be eliminated and subdivided into farms of 20 ac. About half the farms in the eastern zone were of this size by 1952.

Before World War II western Germany imported about 40% of its food and the east German area lacked some foods (*e.g.* meat, formerly secured from Schleswig-Holstein, and supplementary grain from Silesia). The lands taken over after the war by the U.S.S.R. and Poland formerly provided nearly a quarter of Germany's agricultural production. Since the population of the German Federal and Democratic republics is roughly equivalent to the prewar population of the whole Reich the loss of these Prussian areas created a serious problem.

The principal wine-growing districts of Prussia are the Rheingau and the Rhine province. The vineyards are terraced on the stony, southward-facing slopes of the Rhine and its tributaries, especially the Saar and the Moselle. The harvest is so uncertain that the industry can be maintained only by concentration on high-grade wines.

Mining and Power Production.—Prussia was far the largest producer of minerals in the Reich. Seventy per cent of German coal (127,000,000 tons in 1938) was mined in the Ruhr and a further 13% (26,000,000 tons) in Silesia. The high-grade coking coals of the Ruhr were of special importance in the metal industries. The Silesian field came entirely into Polish hands after World War II. The utilization of the Prussian lignite (brown coal) deposits was greatly extended after 1919, the output increasing to more than 250,000,000 tons in 1943. Two-thirds of this came from Brandenburg and the area between Magdeburg and Leipzig, the one-third from the Ville field west of Cologne. Oil is found near Hanover but the output of the wells is far exceeded by the synthetic production from coal and lignite. Most of the home-produced iron ore, only a small fraction of that consumed, was mined in the Hanover area and the Siegerland. Small quantities of ores of copper and of lead and zinc are still obtained from the Harz. Before it lost the Silesian mines in 1919 Germany ranked first in Europe as a zinc producer. The Stassfurt deposits are still an important source of salt, of potash for the chemical industry and of magnesium for the making of aluminum alloys. Before World War II Germany had a larger production of electricity than any other country in Europe, nearly all from thermal stations on or near the lignite (40%) and coal (36%) fields.

Industry.—Of the 14,500,000 people employed in German industry in 1939 about 9,000,000 were in Prussian factories and workshops. The main concentrations were on the Ruhr coal field and along the Rhine front within easy reach of it, on the lignite field of the middle Elbe, and in Berlin and the North sea ports. The iron and steel industry was located on the Ruhr field because of its coke supplies. From its first development until 1919 it used principally the Lorraine ores but since that date has depended on imported (mainly Swedish) ores. Heavy engineering was closely situated around the steelworks but fabrication and light engineering were more widely dispersed; *e.g.*, shipbuilding at Bremen and Hamburg, railway material at Essen and Berlin, motor cars at Frankfurt. The largest manufacturers of electrical machinery had their works in Berlin. The heavy chemical industry, using coal, lignite and potash as basic materials, naturally developed on the Ruhr and the middle Elbe. Finer chemicals were manufactured around Frankfurt. The chief area for textiles was the Wuppertal, south of the Ruhr.

The dismantling of industrial plants and the breakup of the large cartels were prominent features of Allied policy immediately after World War II. The resulting widespread unemployment soon led to a reversal of the former and the latter was applied less drastically than was originally planned. In the German Federal Republic the production of electricity was in 1953 about double the prewar level, lignite exceeded the prewar level, and coal and textiles had reached it. Steel production was still limited to about two-thirds of the old level. In the German Democratic Republic where dismantling was carried much further and a large part of the remaining products were taken by the U.S.S.R. as reparations, output was still low though increasing as earlier restrictions were withdrawn.

Communications.—Prussia was excellently provided with internal means of communication. Its railway network included about 17,000 mi. of track. The main trunk route was from west to east, through Aachen, Cologne, Düsseldorf, Hanover, Berlin, Danzig and Königsberg. Important lines followed the Rhine in the west and radiated from Berlin to link the North sea and Baltic ports with southern Europe. In the years immediately before World War II they were supplemented by the through motor roads (*Autobahnen*). All the rivers are navigable across the plain and these were connected by an extensive canal system. The great Mittelland canal, opened in 1938, joined the Elbe with the Rhine, and the Dortmund-Ems system served the Ruhr area, while the Kiel ship canal gave a short route from Hamburg to the Baltic sea. The division of western and eastern Germany gravely disrupted the whole transport system, cutting off Hamburg from most of its hinterland and Berlin from its North sea ports.

HISTORY

The state of Prussia, which has played so great a part in the history of Germany, came into being gradually, being formed out of wholly dissimilar components. The chief of these were the mark of Brandenburg and the state of the Teutonic Order in Prussia (*i.e.*, the country originally inhabited by Prussians, Prusi or Borussi, a Baltic people speaking a language akin to Lithuanian and Latvian). The history of each of these, up to their union, must be treated separately.

The Teutonic Order.—In 1226 the Polish duke Conrad of Mazovia invited the Teutonic knights into his territory to combat the heathen Prussians. After a difficult struggle, the order conquered the territory, exterminated most of the native population, and invited German peasants and townspeople into the country as settlers. In the 14th century the state ruled by the knights was a power in northeastern Germany. In 1308 it conquered Polish Pommerellia and for a time the Neumark also, and through its connection with the Order of the Sword, of Livonia, extended its influence as far as Estonia. A string of flourishing cities sprang up along its coast. In Marienburg, since 1309 the seat of the

grand master of the order, the splendid castle was built which to this day testifies to the past glories of the order, and formed the centre of its admirably organized administrative system. But even in the 14th century the order was beginning to decline, owing mainly to the fact that once the struggle against the heathen was ended, it lost its original spiritual character, occupied itself only with purely mundane tasks, and thus lost touch with its original purpose. The rule of the knights, who admitted none of the local nobility into their ranks, came to be felt by the inhabitants as a foreign rule. When Poland and Lithuania united into a powerful state at the end of the 14th century, and the rulers of this state began to plan the recovery of the Baltic coast, the order could not rely fully either on the nobles or on the towns in its territory. After the defeat of their army at the battle of Tannenberg (1410) the knights were forced to cede part of their territory to Poland. In a second war the Poles took Marienburg, and at the peace of Thorn (1466) forced the order to cede them West Prussia and Ermeland, with Danzig and Thorn, and to acknowledge the suzerainty of the Polish king for the rest of their territory. At the beginning of the 16th century, the Reformation began to penetrate these regions also, and the grand master of the day, Albert of Brandenburg, a grandson of the elector Albert Achilles, proceeded, with the consent of the king of Poland, to take the decisive step which was tantamount to the end of the order's rule. He went over to Protestantism, at the same time proclaiming himself hereditary duke of Prussia (1525). As his only son, Albert Frederick (1568–1618), was an imbecile, the power passed almost wholly to the estates. Albert Frederick's eldest daughter, Anna, married the elector John Sigismund, and through her Prussia passed in 1618 to the electors of Brandenburg. As Anna was also co-heiress through her mother of the great territories which had been united under the rule of the dukes of Jülich, Cleve and Berg on the lower Rhine, and as this ducal house had become extinct a few years previously (1609), the electors of Brandenburg could hope to acquire not only Prussia, but also considerable domains in west Germany. (*See* BRANDENBURG.)

Frederick William I.—Frederick William I (1713–40), the son and successor of Frederick I, has long been unjustly represented as a crude tyrant. He was a sober-minded man, without any strong intellectual interests, but a first-class organizer and imbued with a stern sense of duty, based on religious sentiment, and he devoted his whole soul to the service of the state. He resumed the work begun by his grandfather, the Great Elector, and is the true father of the Prussian administrative system and Prussian officialdom. He created a new central administrative service in the shape of the general directory, for which he drew up the instructions himself (1723). This organ acted as a general ministry, in which the agenda was distributed to the several members, partly by subject, partly on local lines, while all important measures were decided in general conference. The king reserved to himself the final decision. Each official received a commission stating his duties, emoluments and exact official regulations. All official bodies had to keep a record of, and send in a weekly report on, their activities. In most cases officials were nominated by the king at his discretion; only in the selection of the *Landräte*, who were in charge of the provincial districts (*Kreise*) the nobles still had a certain voice. Officials and magistrates were obliged to pass through a definite course of training, and could not be appointed unless they had passed the prescribed examination. The king organized a regular procedure of judicial appeal, making the *Kammergericht* in Berlin the supreme judiciary instance for the whole state. Judicial procedure was also simplified and improved in important respects. In the financial administration he introduced the strictest economy. He succeeded in increasing the revenue from the royal domains and prerogatives and from the indirect taxes to a considerable degree, and in achieving an annual surplus. This he put into a state exchequer, which contained 7,000,000 thaler at his death. He made special efforts to encourage trade and industry, following the principles of the mercantile system (*q.v.*), which at that time were everywhere accepted. As the country was thinly populated, he encouraged the immigration of efficient labour. Just as his grandfather had admitted a large number of the Huguenots expelled from France after the repeal of the Edict of Nantes by Louis XIV, so Frederick William allowed the Protestants expelled by the archbishop of Salzburg to enter his kingdom, settling most of them in East Prussia. Foremost a soldier, the king devoted particular attention to the training of the standing army, the numbers of which he raised from 40,000 to 80,000. It was still a mercenary army, recruited from volunteers at home and abroad. He took pains, however, to ensure that as high a proportion as possible should be composed of his own subjects and divided the whole Prussian territory into recruiting districts, the so-called "cantons"; each district was obliged to supply the men for one specified regiment. The recruiting was often done in a very arbitrary fashion, which gave rise to many complaints. Definite instructions were drawn up and regular inspections carried through to ensure uniformity of training; the army thus created was superior to those of most other states. It was Frederick William who first gave Prussia the characteristic stamp of a military and bureaucratic state.

For all his military inclinations, Frederick William was a peaceable man by nature, and in his foreign policy always avoided military entanglements. When he came to the throne, Prussia was embroiled in the Northern War; at the conclusion of peace he succeeded in securing Western (Hither) Pomerania up to the Peene, which had formerly been in the hands of Sweden, with the important commercial town of Stettin. He failed, however, to secure support for his claims, which were based on old succession treaties, to further portions of the Cleve-Jülich heritage and to parts of Silesia. As a loyal German, he thought it his duty to maintain as good relations as possible with the emperor; but encountered profound mistrust in Vienna, where the growing strength of the Prussian state was watched with concern, and toward the end of his life was forced into an increasingly sharp opposition to the house of Habsburg.

Frederick the Great.—Frederick William died in 1740. He was succeeded by his son, Frederick the Great (1740–86), who was at that time 28 years of age. He had had violent conflicts with his father in his younger days, as his passionate and freedom-loving nature revolted against the severe discipline which his father thought necessary. Furthermore, the younger man's inclinations led him toward the new ideas of the *Aufklärung*, while the old king was a strict Calvinist. The crown prince's attempted flight (1730) brought this conflict to a head. The king had his son imprisoned, and even had an idea of excluding him from the succession; Frederick was only able to buy a reconciliation at the price of complete submission to his father's will. He was obliged to pass through a strict training in the administrative service and the army, a training which did much to prepare him for his later career.

For Frederick's conflicts with Maria Theresa in the first half of his reign, see AUSTRIA, EMPIRE OF; AUSTRIAN SUCCESSION, WAR OF; GERMANY; SILESIA. They ended in the acquisition of Silesia, with the exception of a few small districts south of the Riesengebirge, which remained in the hands of Austria. Frederick's successful resistance in the Seven Years' War against Austria, France and Russia raised his prestige enormously. From this time onward his state was recognized as a European great power. In addition to Silesia, he had also acquired East Frisia which came to him in 1744 on the extinction of the old princely house, through a succession treaty. At the first partition of Poland (1772) he also acquired West Prussia (except Danzig and Thorn), a particularly important district because it bridged the gap between East Prussia and the Brandenburg family dominions. Frederick carried on the internal development of the Prussian state on the lines laid down by his father. He instituted a general civil code for his state in the shape of the Prussian *Landrecht*—a work not completed until after his death; accelerated judicial procedure, abolished torture, and introduced the principle that the crown should not interfere with the course of justice. In administrative matters, he sought to pay special consideration to the local peculiarities of the different provinces, and made frequent journeys of inspection to satisfy himself that his orders were being carried out. The fiscal system was further developed; but an attempt to introduce the

farming of taxes, on the French model (1766), proved unsuccessful and had to be abandoned. Under his rule the state revenue increased largely; on his death he left 55,000,000 thaler in the state exchequer. He had the low-lying country of the Oder and the Warthe drained, settled villages of colonists in the Pomeranian forests, arranged for the plantation of hops and potatoes, and founded factories. He left several detailed exposés of his administrative and political principles, notably in his political testaments of 1752 and 1767, which were designed to serve as a guide to his successor. Like his father, he considered himself the first servant of the state, and said that the prince should govern as though he had to render account to his subjects for all his measures. It did not, however, occur to him to do so. He rarely consulted with his ministers in person; he called for reports from them in writing, and dictated the answers, which he sent to them in writing. His liberal views in matters of religion led him to adopt the policy of toleration, on principle, toward the different churches: a policy which was also naturally dictated by practical considerations in a state which included a Protestant majority and a Catholic minority. His lively interest in all intellectual questions led him to take measures to improve the level of public education. In the upper schools the classics were made the principal subject of instruction. The king wished to establish compulsory primary education for all children from 5 to 13, but lack of means made it impossible to carry this out. Although Frederick was deeply influenced by the humanitarian ideas of the *Aufklärung,* and considered the furtherance of the people's welfare and of popular education to be among the monarch's essential duties, yet his guiding thought remained always to raise the forces of his comparatively small, weak state, by better organization, so as to maintain the position of power which he had won.

Collapse and Reform.—As Frederick left no issue from his marriage, contracted at his father's orders, with a princess of Brunswick, and as his younger brother, Augustus William, had predeceased him, the latter's son, Frederick William II, succeeded him on the throne (1786–97). He was indolent and dissipated, squandered the state exchequer and left the cares of government to his favourites. Under his reign no progress was made in the domestic organization of the state. In foreign affairs his participation in the war against revolutionary France brought him only losses, while the large accessions of territory that the second and third partitions of Poland (1793 and 1795) brought him were gains of but doubtful value. For the Prussian state, which after 1795 extended as far as Warsaw, thus received so large a percentage of Polish blood that had these frontiers proved permanent, its German character would have been endangered.

His son, Frederick William III (1797–1840), was a man of the best intentions, but pedantic, vacillating and narrow. The government fell more and more into the hands of the cabinet councillors who, under the system introduced by Frederick the Great, formed the sole channel of communication between the king and the ministers. But while under Frederick the councillors had been only executive organs of the king's will, under his weak successors they became the all-important personal advisers of the monarch. The Prussian state still kept the outward form given it by Frederick William I and Frederick the Great; but the living spirit was gone from it, and its swift and complete collapse after the first great military reverse (Jena, 1806), is easily comprehensible. Under the peace of Tilsit (1807) Frederick William was obliged to cede his entire territory west of the Elbe and the greater part of his acquisitions in Poland; he retained only Brandenburg, Pomerania, Prussia and Silesia. This fearful collapse, however, also released the forces of reconstruction which still lived on within the state, and during the so-called "period of reform" a complete reconstruction of the state was begun. The king himself always remained disassociated from, and at heart hostile to, these efforts, which appeared to him as a concession to Jacobinism; but as he knew no plan of his own for reconstructing the shattered state, he was forced to let the apostles of the new ideas have their way.

Heinrich, baron vom und zum Stein became the leading figure in the administration. He had long been urging reforms, but before 1806 without success. His fundamental idea was that in a modern state the people itself must be required to help in the conduct of public affairs because the state cannot exist unless it can count upon the willing co-operation and devotion of its citizens. The most important measures which he carried through were the liberation of the peasants from serfdom, the reintroduction of municipal self-government under the Municipal act of 1808, and the abolition of cabinet government. He also planned to introduce self-government in the rural districts and participation of representatives of the people in the provincial administration and the central government. He was unable, however, to carry these measures into practice, being dismissed in the autumn of 1808 at Napoleon's order. The reforms were taken up again by Karl, prince von Hardenberg, in 1810, on his appointment as head of the ministry, although on lines rather different from those intended by Stein. Hardenberg really inclined more to enlightened despotism than to Stein's idea of self-government. His principal achievements were the reorganization of the finance and of the administrative system, the abolition of restrictions in industrial life, and the edict of 1811 which made the peasants free proprietors of their holdings, in return for the cession of a part of them to the former landlords. The peasants were thus required to buy their ownership at the price of giving up part of their holdings. Moreover, as the smaller holdings were excluded from the measure, the landlords could now take full possession of them, and their former cultivators sank to the position of agricultural labourers without property.

These years also saw a great reorganization of the army, carried through by Generals Gerhard von Scharnhorst and Hermann von Boyen. The underlying principle was the transformation of the mercenary army into a national army. Universal service was introduced, degrading punishments abolished, admission to the corps of officers revised and the internal organization of the army rearranged in more practical form. But for these reforms in all directions, the little state would have been incapable of the great achievements which it performed during the War of Liberation.

The Congress of Vienna.—After Napoleon's defeat in Russia, the Prussian General Hans Yorck von Wartenburg took his forces over to the Russian side and Frederick William III reluctantly followed his lead. The Prussian army played a principal part in the overthrow of Napoleon and Prussia re-emerged as a great power. At the Congress of Vienna, Prussia did not recover its Polish lands lost in 1807, which now went to Russia. In compensation it received Western Pomerania, the northern half of the kingdom of Saxony, Westphalia and the Rhineland. Its population was increased from under 6,000,000 to 10,000,000. Prussia ceased to be a northeastern German state and straddled across Germany. For the first time also it counted a large number of Roman Catholics amongst its people.

In the excitement of liberation the king had promised a constitution; after 1815 the promise was ignored. All that remained of it was the assurance that the state would not raise any new loan without the consent of an elected body. Meetings of the estates were introduced for the individual provinces, but they were given only an advisory voice in local affairs. Prussia continued to be run by the old nobility and bureaucracy, who were increasingly out of touch with the liberal sentiment of the western provinces. The only striking advance in the reign of Frederick William III was the creation of the *Zollverein* (virtually complete by 1834) which brought all the German states except Austria under Prussian economic leadership.

The 1848 Revolution.—On the death of Frederick William III, his eldest son Frederick William IV (1840–61) ascended the throne. He had grown up in an age when the theories of romanticism had dominated Germany; these theories swayed him, and, like his father, he was averse at heart to the modern political demands. After long consideration, however, he determined in 1847 to convoke the members of all provincial diets to a united diet at Berlin. This body, however, immediately put forward a demand to be convoked at regular intervals, and to be recognized as a partner, with equal rights, in the legislation. The king refused to admit such claims, and the deliberations led to no practical result. Nevertheless, it was an event of no small importance

that representatives of all parts of the Prussian state had, for the first time, met for common parliamentary debates.

Soon after this, revolution broke out all over Germany. Although the military remained the victors in the street fighting of March 18 in Berlin, the king nevertheless decided to give way and withdraw the troops from Berlin. He agreed to the convocation of a constituent national assembly, which was to meet in Berlin and collaborate with him in drawing up a constitution. But as democratic elements gained the upper hand in this assembly, the king dissolved it and enacted a constitution (Dec. 5, 1848), with the proviso that a freshly elected parliament should negotiate further on its final form. These negotiations proving very protracted, the parliament was again dissolved in the spring of 1849, and it was only when a chamber was elected on the three-class franchise that agreement was at last reached on a definitive constitution, to which the king took the oath on Feb. 4, 1850. Prussia now received a parliament, consisting of two chambers; the first chamber, called the *Herrenhaus* after 1854, was composed of representatives of the large landed proprietors and of the larger towns, and of members nominated by the king, either for life, or as hereditary members. The second chamber was elected by all taxpaying citizens, but as the electors were divided into three categories, according to taxes paid, electors with larger incomes were given much greater influence than the poorer classes. Yet, despite the limited franchise, this was a genuine constitution. The chambers had defined rights and were entitled to meet regularly. The budget was to be agreed annually between the chambers and the crown—a phrase which seemed to imply, though it did not, a large measure of parliamentary sovereignty. Inadequate as the constitution appears by democratic standards, without it there would have been later no constitutional conflict at all.

During the revolution of 1848 Frederick William IV hoped to lead the movement for unification. He said in a famous phrase: "Prussia is merged in Germany." His conservative principles soon reasserted themselves. On April 3, 1849, he refused the imperial crown, when it was offered to him by the Frankfurt national assembly; he would only accept it, he said, from the German princes. He and his friend Joseph Maria von Radowitz attempted to build a lesser German union, on conservative lines, known as the Erfurt union. In 1850 this was challenged by Austria; and as Frederick William shrank from war, Prussia was obliged to abandon its ambitions by the agreement of Olmütz or Olomouc (Nov. 2, 1850).

William I and William II.—A period of reaction followed in Prussia. Frederick William IV appointed an extremely reactionary government, which remained in power until he became insane in 1857. His brother, William, prince of Prussia, acted as regent until his death (Jan. 2, 1861) and then ascended the throne as William I. The new ruler took at first a more liberal line than his brother. In 1858 he appointed a liberal ministry under Prince Hohenzollern, and for nearly four years Prussia experienced "the new era." William and his minister of war, Albrecht, count von Roon, disagreed, however, with the chamber over the reorganization of the army. Roon wished to increase the army establishment, which had remained stationary since 1815, so that every Prussian should perform his military service. The lower chamber were ready to agree with this, but insisted in return that the period of service be reduced to two years and that the *Landwehr*, or reserve, should play a more independent part. The struggle which followed was a conflict over the character of the Prussian army, not its size. By the constitution, the taxes were imposed permanently. The chamber could not cut off supplies. It could only refuse to authorize the expenditure of money already collected. In 1861 they authorized the additional expenditure for a single year. In 1862, as their demands were still refused, they refused authorization altogether. William first thought of abdicating. At the last minute Roon persuaded him to appoint Otto von Bismarck minister president (Sept. 23, 1862).

As the lower chamber refused to accept the budget which the king and the upper chamber had put forward, Bismarck argued that there was "a hole in the constitution"; and he governed without a budget for the next few years. The liberals were helpless. It would have been unconstitutional to refuse the taxes. They could only protest and wait for Bismarck to fail in his foreign policy. Instead he succeeded, and his defeat of Austria in 1866 led many liberals over to his side. He in turn was willing to confess the illegality of his actions. He asked for and received an Act of Indemnity (Sept. 1866).

Campaigns of 1864–71 which led to union of Germany under Prussia's leadership cannot be told here. (*See* SCHLESWIG-HOLSTEIN QUESTION; GERMANY; AUSTRIA, EMPIRE OF; FRANCO-GERMAN WAR.) The acquisition of Hanover, Kurhesse, Nassau and Frankfurt-am-Main after the war of 1866, gave Prussian territory a wholly new aspect. Its eastern and western halves, which up to this date had been separated by these districts, were now linked up into a single great north German state, containing nearly two-thirds of the total population of Germany (in 1914, 40,000,000 out of a total population of 67,800,000).

With the unification of Germany in 1871 the king of Prussia became German emperor, in supreme command of all German armed forces. The Prussian army was, in fact, the main instrument by which Prussian power was extended throughout Germany. Bismarck also combined Prussia and Germany in his own person. He was both political head of the empire as *Reichskanzler* and Prussian minister president. Roon was Prussian minister president for a short period in 1872–73; but when he fell ill Bismarck resumed the office and kept it until 1890. His successor Georg Leo von Caprivi gave up the position of Prussian minister president; but this led to a conflict of policy between the two offices and ultimately to his resignation. The two posts were then reunited until the end of the empire in 1918.

The alliance concluded by Bismarck with the liberals at the time of the foundation of the empire had important effects. The Local Government act of 1872 increased the autonomy of the rural districts, thus linking up with the traditions of the age of Freiherr von Stein. The so-called *Kulturkampf*—the struggle against the Roman Catholic Church which was waged in the '70s—was also in accord with liberal ideas. It ended, however, finally, with the state restoring to the church its control over the preliminary training of the clergy, and retaining only a right of veto over appointments to ecclesiastical posts.

During the short reign of Frederick III (March–June 1888) and under William II, the situation remained in essence unchanged. The new Rural Districts act (*Landgemeindeordnung*) of 1892 carried existing institutions a step further. The fiscal reform carried through about the same time by J. von Miquel made self-assessment the basis of taxation, and provided relief for the poorer classes and heavier contributions from large incomes.

Reform of the franchise was often discussed, to give Prussia the same universal suffrage as the reich; but these proposals never came to anything, and the three-class franchise survived until the revolution of 1918.

Republic of Prussia.—The revolution ended the Prussian monarchy. It also severed the connection between the Prussian prime minister and the imperial chancellor. Prussia became a *Land* of the Weimar republic, with the same universal suffrage. Since Prussia was the most industrialized part of Germany, its parliament had always a left-wing majority. Prussia was ruled between 1918 and 1932 by the Social Democrats, sometimes alone, sometimes in coalition with the Centre. The most outstanding personality was Otto Braun, the prime minister. Since the *Land* controlled the police, the Social Democratic government of Prussia was the essential defense of German democracy.

In 1932 the coalition of Centre and Social Democrats lost their majority. Franz von Papen, then chancellor, used this excuse to overthrow Prussian democracy. He was nominated imperial commissioner for Prussia by Pres. Paul von Hindenburg and expelled the democratic government. This made easier Hitler's accession to power on Jan. 20, 1933. Soon afterward Hermann Göring took Papen's place as ruler of Prussia. The Prussian constitution was set aside by the National Socialists, its legislature was abolished but it still led a nominal existence as a component part of the reich. (*See* also BRANDENBURG; GERMANY.)

(E. BRA.; A. J. P. T.)

PRUSSIA, in the original sense, a territory of Germany, stretching along the Baltic coast for about 220 mi. and occupying an area of 24,083 sq.mi. The eastern part of this territory formed the duchy of Prussia, conquered and colonized by the Teutonic order and acquired by the elector of Brandenburg in 1618, furnishing his successor with his regal title in 1701. The western part, severed from the eastern half and assigned to Poland in 1466, was not annexed to Prussia until the partition of Poland in 1772, while the towns of Danzig and Thorn remained Polish down to 1793. The two districts were temporarily (1824–78) united to form a single province.

PRUSSIC ACID (HCN), also known as hydrocyanic acid or hydrogen cyanide, is a highly volatile, colourless liquid of extremely poisonous character. It was discovered in 1782 by K. W. Scheele, who obtained the compound from Prussian blue. In variable but generally small proportions it is widely distributed among plants in the form of glycosides; *i.e.*, in combination with sugars. Amygdalin (*q.v.*), which is present in bitter almonds, is an example of such glycosides; it yields prussic acid upon hydrolysis.

Preparation.—A convenient method of obtaining prussic acid in the laboratory is to add a cold mixture of 100 c.c. concentrated sulphuric acid and an equal volume of water slowly to 100 g. of coarsely granular potassium cyanide in a large flask connected to two U-tubes filled with anhydrous calcium chloride. The vapours emerging from these U-tubes are condensed by passing downward through a condenser and collected. Brine cooled to −10° C. is circulated through the jacket of the condenser. A fully anhydrous product is made by adding phosphorus pentoxide to the liquid thus prepared, shaking for a short period, and distilling once more.

Prussic acid is made commercially from sodium cyanide in a continuous manner, by bringing together a 23% aqueous sodium cyanide solution and 66° Bé sulphuric acid in a lead-lined generator, and condensing and collecting the vapours evolved. The sulphuric acid is kept slightly in excess over the cyanide in the course of the reaction. The residual prussic acid in the liquid, which forms 20% of the total, is recovered by boiling the solution, the vapours being condensed after a partial enrichment in a special "cooler." Prussic acid of 97.5%–98% strength is made from the combined crude condensate by fractional distillation. Large quantities of the acid are also prepared from commercial calcium cyanide by a similar process.

Important quantities of prussic acid are made in Germany from "Schlempe," a by-product of the sugar industry resulting from the treatment of beet molasses with strontia for the purpose of recovering the sugar present in this product. Schlempe contains 4% of nitrogen in the form of betaine, $(CH_3)_3N^+-CH_2-CO_2^-$, in addition to decomposition products of vegetable proteins. It is first distilled, the tarry matter carried over by the vapours being condensed and separated; the gases escaping the condenser are next preheated by passage through a tunnel in an externally heated chamber and are then conducted through the cyanizing chamber. This chamber is filled with firebrick checkerwork and is previously heated by direct gas fire to a temperature somewhat in excess of 1,000° C. The cyanized gas contains about 7% prussic acid, 7% ammonia and 24% carbon dioxide by volume. It is freed of ammonia by scrubbing with hot, dilute sulphuric acid. The prussic acid in the emergent gases is absorbed in water; and the aqueous solution thus obtained, which contains 2%–3% prussic acid, is fractionally distilled to recover the prussic acid. The acid is condensed to liquid and further refined, or it is directly converted to sodium cyanide.

Synthetic Methods.—Several possible methods for the synthesis of prussic acid have been investigated. Two such methods developed into successful commercial processes and became employed for the preparation of the compound on a very large scale. A brief description of these processes follows.

Synthesis by Controlled Oxidation of a Hydrocarbon Ammonia Mixture.—Prussic acid is formed when a mixture of methane and ammonia, containing an insufficient amount of oxygen for complete combustion, is passed through a glowing platinum gauze. The reaction giving rise to the compound may be expressed as $2NH_3+2CH_4+3O_2 \rightarrow 2HCN+6H_2O$. Leonid Andrussow, who discovered this method, developed it into a successful technical process.

Methane and ammonia are mixed in the approximate ratio 11:10, and sufficient air is added to the mixture to give an oxygen content of about 15.5%. The mixture is passed through two or more layers of incandescent platinum iridium gauze with 3% to 5% iridium. The gauze is constructed of 0.16-mm. wire. The several layers of the gauze, resting on a special support, are held between ceramic rings inside a short tube, the whole constituting the converter. The cold gases enter the converter usually at a linear velocity of 103 cm. per second, emerging at a temperature of 1,000°–1,030° C. at a little over 500 cm. per second. The heat generated by the reaction is sufficient to maintain the gauze at the desired temperature. The gases emerging from the converter may be passed through sodium hydroxide solution, after being cooled sufficiently. The prussic acid is quantitatively absorbed, and may be recovered as sodium cyanide. Alternatively, the ammonia is removed by scrubbing with dilute acid, and the prussic acid is absorbed in cold water in special towers and recovered by distillation.

Of the total ammonia fed into the converter, approximately 63% is utilized in the formation of prussic acid, and 10% to 20% is lost by complete combustion. Platinum losses resulting from catalyst deterioration amount to about 1 g. per metric ton of hydrocyanic acid produced.

Aliphatic hydrocarbons other than methane are capable of undergoing the reaction. Methane receives preference, however, since higher hydrocarbons tend to deposit carbon and cause what is known as spotting of the catalyst. This results in loss of efficiency and a greater rate of deterioration of the gauze.

Synthesis by Dehydration of Formamide.—In this process formamide is dehydrated in the vapourized condition by passing it, in admixture with a large proportion of ammonia, over an aluminum phosphate catalyst heated to 360° C. The reaction expressing the change is $HCONH_2 \rightarrow HCN+H_2O$. The original formamide ammonia mixture contains 3%–5% of formamide. Dehydration is carried out at atmospheric pressure and proceeds very rapidly. The prussic acid formed is absorbed in sodium hydroxide solution and may be recovered as sodium cyanide.

Formamide is prepared through the reaction of anhydrous ammonia with methyl formate at 30°–60° C. under a pressure of 15 atm.: $HCOOC_2H_5+NH_3 \rightarrow HCONH_2+CH_3OH$. It is purified to analyze 99.7% by fractional distillation. Methyl formate is made by the reaction of carbon monoxide with methyl alcohol in the presence of 1% sodium as sodium methoxide: $CO+HOCH_3 \rightarrow HCOOCH_3$. The reaction is carried out at 110° C. under 100 atm., and proceeds quite readily with evolution of heat. The product is freed from the dissolved sodium methoxide by distillation, and the mixture of methyl formate and methyl alcohol thus obtained is used directly for the preparation of formamide. The methyl alcohol recovered in the distillation step contains a small amount of unreacted methyl formate and is used for the preparation of additional quantities of methyl formate. The process is, therefore, essentially a complete synthesis of prussic acid, utilizing ammonia and carbon monoxide as the starting materials.

The yield of prussic acid based on ammonia exceeds 92%; it is somewhat more than 85% when calculated on the basis of carbon monoxide used. Approximately 5.5 lb. of methyl alcohol are lost in the process for every 100 lb. of prussic acid produced. The catalyst, if it should become deactivated by a coating of carbon, is reactivated by blowing air through the heated mass. It can be used for several years before it becomes necessary to replace it.

Physical and Chemical Properties.—Prussic acid boils at 25.7° C. and freezes to a snowlike, white mass melting at −14.9° C. It is highly volatile even in the frozen condition. The dielectric constant of prussic acid is the second-highest known, indicating the strongly polar character of its molecule. In this respect, the compound bears a great resemblance to water, and like water it is a strongly ionizing solvent. The abnormally high heat of evaporation of the liquid is also ascribable to the highly polar character of the molecule. Prussic acid is miscible in all proportions with water and most organic solvents. The vapours

of prussic acid are combustible and mixtures with air containing 7%–40% prussic acid by volume are explosive. The products of combustion are carbon dioxide and nitrogen.

The elements in the molecule of prussic acid may be combined in one of two possible ways, H—C≡N or H—N=C, designated respectively as the normal (nitrile) and the iso (carbylamine) forms. The fact that both methyl cyanide, $CH_3—CN$, and methyl isocyanide, $CH_3—NC$, result from the reaction of prussic acid with diazomethane, CH_2N_2, would seem to indicate that both forms co-exist in liquid prussic acid, possibly in a state of dynamic equilibrium (*see* ISOMERISM: *Tautomerism*). Evidence indicates that the molecules of normal structure largely predominate in the liquid.

The dissociation constant of prussic acid in aqueous solution at 18° C. is 1.3×10^{-9}, or $\frac{1}{230}$ that of carbonic acid, which is itself a weak acid. The degree of acidity developed in aqueous solution is, for this reason, too small to affect the colour of most indicators (*q.v.*). The vapours of prussic acid react with remarkable rapidity, nevertheless, with solutions of alkalies, which can therefore serve effectively for the elimination of the compound from a stream of air containing prussic acid.

Polymerization of Prussic Acid.—Prussic acid in the pure form is stable and can be kept unchanged almost indefinitely in sealed glass containers. The acid gradually polymerizes in the presence of minute amounts of substances of basic character such as ammonia, sodium cyanide, etc. The polymer is a black solid of approximately the same empirical composition as prussic acid. Polymerization is accompanied with the evolution of considerable heat and is greatly accelerated as the temperature rises. For this reason, the polymerization of comparatively large quantities, which may cause a great rise in temperature with the consequent rise in pressure, may result in an explosion. The addition of small quantities of a strong acid, or of compounds giving rise to acids by gradual reaction with water, effectively stabilizes the commercial acid.

Chemical Behaviour.—Prussic acid cannot be esterified directly. Its esters, R—CN (*i.e.*, the nitriles), are usually obtained through the interaction of an alkali metal cyanide with an organic halide or sulphate. Methyl cyanide can, for example, be prepared by heating methyl iodide with an alcoholic solution of potassium cyanide, according to the equation: $KCN + ICH_3 = CH_3CN + KI$. The fact that nitriles, R—CN, may be prepared through the dehydration of the amides of the corresponding acids, $R—CONH_2$, definitely demonstrates that these compounds are normal cyanides, R—C≡N. The reaction of organic halides with silver cyanide or mercuric cyanide leads to the formation of isonitriles, R—N=C, which differ in their properties from normal nitriles.

Prussic acid combines with aldehydes and ketones in the presence of small quantities of substances of basic character, such as potassium cyanide or amines, generally at room temperature, forming cyanohydrins. Acetaldehyde cyanohydrin results, for example, from the reaction of acetaldehyde with prussic acid: $CH_3CHO + HCN = CH_3CH(OH)CN$.

Prussic acid is capable of reacting with ethylene oxide under pressure in the presence of a basic catalyst at a moderately high temperature, to form ethylene cyanohydrin: $\overline{CH_2—CH_2O}+ HCN \rightarrow HOCH_2CH_2CN$. This compound is readily dehydrated on distilling in the presence of certain catalysts to acrylonitrile, $CH_2=CHCN$. This is the basis of the technical preparation of the latter compound, which has assumed great importance. Acrylonitrile, together with butadiene, is used in the preparation of the acrylic type of synthetic rubber. In the polymeric form it is used for the manufacture of an important synthetic fibre. Another commercial synthetic fibre is made from the copolymer of acrylonitrile and vinyl chloride.

Chlorine, reacting with prussic acid in dilute aqueous solutions, gives cyanogen chloride, ClCN: $2HCN + Cl_2 = ClCN + HCl$. Bromine reacts similarly, forming cyanogen bromide.

The cyano group, C≡N, present in prussic acid, is capable of various transformations because of the reactive, or "unsaturated" character of the nitrogen-to-carbon bonds. The addition of water, or hydrolysis, can take place in steps, the formation of formamide, $HCONH_2$, being the first stage and that of ammonium formate, $HCOONH_4$, the second stage of the reaction. Hydrolysis takes place readily in the presence of concentrated hydrochloric acid, or moderately concentrated sulphuric acid. Concentrated sulphuric acid destroys the ammonium formate, the final products of the reaction being ammonium sulphate and carbon monoxide. Four atoms of hydrogen may be added to the molecule of prussic acid to obtain methylamine, $CH_3.NH_2$. Addition may be brought about by passing a mixture of prussic acid with a large excess of hydrogen over platinized asbestos heated above 150° C.

Metallic Cyanides.—The cyano group or radical behaves in many respects like an element and, combining with metals, gives the metallic cyanides which resemble the metallic halides. This resemblance is particularly marked in the case of alkali metal salts. The radical shows a marked power, on the other hand, of forming complex salts, such as potassium ferrocyanide, $K_4Fe(CN)_6$. In these compounds, usually, one metal atom forms part of the complex cyanide anion. For example, potassium ferrocyanide dissociates into the potassium cations, K^+, and ferrocyanide anions, $Fe(CN)_6\equiv$. Ferrous ions, F^{++}, and cyano ions, CN^-, are present in the solution in such minute quantities, in this instance, that ordinary analytical tests fail to reveal their presence; and the stability of the complex is such that the addition of a mineral acid yields the corresponding free ferrocyanic acid, $H_4Fe(CN)_6$. This behaviour is common to many, but not by any means all, of these complex salts. Some, like potassium zinc cyanide, $K_2Zn(CN)_4$, are easily decomposed by acids with the liberation of prussic acid.

The tendency to form complex cyanides is most marked in the metals of Group VIII, and contiguous metals (transition elements, *see* PERIODIC LAW, THE). Most complex cyanides are of the following types: $K[R(CN)_2]$, where R is Cu, Ag, Au; $K_2[R(CN)_4]$, where R is Zn, Cd, Hg, Ni, Pd, Pt; $K_4[R(CN)_6]$, where R is Cr, Mn, Fe, Co, Ru, Os, Ir; $K_3[R(CN)_6]$, where R is Cr, Mn, Fe, Co, Rh, Ir; $K_4[R(CN)_8]$, where R is Mo or W.

Sodium Cyanide is one of the two commercially most important salts of prussic acid. It is prepared in a pure form, analyzing 96%–98% NaCN, by the Castner process which utilizes the reaction of metallic sodium with ammonia and charcoal. A less pure form of the compound is made from prussic acid. In Germany a large portion of the prussic acid obtained from Schlempe is converted to sodium cyanide.

The Castner Process.—Metallic sodium is melted with charcoal in a steel vessel and dry ammonia is blown into the liquid, while the temperature is gradually raised to 600° C.; the mass is finally heated to about 850° C. in order to complete the conversion of the last remaining portion of sodium cyanamide into cyanide. The molten mass is filtered through iron turnings, after being cooled to some extent, and is cast in moulds in the form of spheroids of convenient size. The reaction proceeds in three steps: sodium amide is the first product, $Na + NH_3 = NaNH_2 + H$; the amide reacts rapidly with charcoal forming sodium cyanamide, $2NaNH_2 + C = Na_2CN_2 + 2H_2$; and this finally combines with an additional atom of carbon to form sodium cyanide, $Na_2CN_2 + C = 2NaCN$.

Preparation from Prussic Acid.—Prussic acid is absorbed in aqueous sodium hydroxide solution of such strength that a saturated solution of sodium cyanide (45% by weight) is produced. The use of an excess of prussic acid is avoided, since otherwise a dark product is obtained, because of the polymerization of the free acid. The solution is evaporated *in vacuo* to a paste, which is centrifuged to give a product containing 10% water. The remaining water is removed by drying this product on heated trays *in vacuo*. The dried powder, which analyzes 90%–92% NaCN, is compressed into rectangular cakes of convenient size.

Properties of Sodium Cyanide.—Sodium cyanide is a colourless solid crystallizing in the cubic system. It forms a dihydrate, $NaCN.2H_2O$, which crystallizes in large colourless plates decomposing above 34.7° C. Sodium cyanide is soluble in water, alcohol and anhydrous ammonia; it melts at 563.7° C.

In aqueous solution, sodium cyanide is partially hydrolysed to prussic acid and sodium hydroxide: $NaCN+H_2O=NaOH+HCN$. When aqueous solutions of sodium cyanide are heated, hydrolysis of the cyano group takes place at an appreciable rate, and ammonia and sodium formate result: $NaCN+2H_2O=HCOONa+NH_3$. This reaction also takes place at ordinary temperatures, although at an extremely slow rate.

Calcium Cyanide has acquired considerable commercial importance since its preparation from cyanamide: a mixture of 10 parts commercial calcium cyanamide, 8 parts common salt and 0.5–1 part calcium carbide is fed into an electric furnace of the arc-resistance type with conducting hearth and a single suspended graphite electrode. Alternating current passing through the charge heats this to 1,200°–1,400° C., and the fused mass overflows to a pan in which an internally water-cooled rotating drum picks up a thin layer of the melt. The cyanide is thus chilled rapidly in the form of a thin sheet which breaks into flakes as it is scraped off and collected. The product analyzes more than 45% $Ca(CN)_2$ and contains impurities derived from the coal and coke used in the manufacture of cyanamide and from the salt. Calcium cyanide is formed through the combination of calcium cyanamide with carbon. The carbon is present in the commercial product in the required amount because of its mode of formation from carbide: $CaC_2+N_2=CaCN_2+C$. Rapid cooling of the fused cyanide is essential for the prevention of reversion to cyanamide, which takes place rapidly between 400° C. and 700° C.

Calcium cyanide in the pure form is a white powder which melts at 640° C.±30° C., when heated rapidly, to a clear liquid. The melt soon becomes turbid and finally solidifies as it reverts to calcium cyanamide. An important property of calcium cyanide is its reaction with atmospheric moisture which takes place according to the equations:

$$Ca(CN)_2+H_2O\rightarrow Ca(OH)CN+HCN;$$
$$Ca(OH)CN+H_2O\rightarrow Ca(OH)_2+HCN.$$

The reaction takes place rapidly if the cyanide is finely ground and the relative humidity is in excess of 35%. It forms the basis of the use of calcium cyanide as a fumigant.

Heavy Metal Cyanides.—The simple cyanides of heavy metals are insoluble in water, with the notable exception of mercuric cyanide. Cuprous, silver and zinc cyanides have acquired some commercial importance.

Cuprous Cyanide, CuCN, the only stable cyanide of copper, is made by adding a solution of sodium cyanide to one of cuprous chloride in saturated aqueous sodium chloride. It is soluble in solutions of alkali metal cyanides. The complex salts obtained through the combination of cuprous cyanide with alkali cyanides are used in the electrodeposition of copper on iron. Cuprous cyanide is also important as a reagent for the introduction of the CN radical into aromatic compounds by reaction with aromatic diazo compounds.

Silver Cyanide, AgCN, separates as a white flocculent precipitate when hydrocyanic acid is added to an aqueous solution of a soluble silver salt. It dissolves in sodium cyanide solution, forming the complex salt $NaAg(CN)_2$, which is used in the process of electrodeposition of silver.

Zinc Cyanide, $Zn(CN)_2$, may be prepared by adding hydrocyanic acid to a solution of zinc acetate in water. It separates as white crystals which dissolve in solutions of alkali cyanides, with the formation of a complex cyanide.

Potassium Ferrocyanide, $K_4Fe(CN)_6$, together with the corresponding sodium salt, finds wide use in the preparation of Prussian blue, in the dye industry for the fixation of aniline black dyes and in the casehardening of iron by the "cementation" process. It may be prepared through the reaction of ferrous sulphate and potassium cyanide in aqueous solution. It is obtained more economically from commercial calcium cyanide. Commercial calcium cyanide is dissolved in water and treated with the calculated quantity of ferrous sulphate. To the filtered solution potassium chloride is added, thus precipitating the nearly insoluble potassium calcium ferrocyanide, $K_2CaFe(CN)_6$; this is filtered, washed and then boiled with the required quantity of aqueous potassium carbonate solution. The solution is filtered and concentrated by boiling in cast-iron vessels, and the salt is allowed to crystallize during 14 days on wires or strings suspended in the liquid. The sodium salt may be prepared similarly by the use of sodium chloride and sodium carbonate in the process in place of the potassium salts.

Potassium Ferricyanide, $K_3Fe(CN)_6$, is prepared by oxidizing potassium ferrocyanide in aqueous solution electrolytically or with chlorine. Electrolysis is carried out in diaphragm cells with nickel electrodes. Potassium ferricyanide crystallizes out from the anode liquor on cooling, and the mother liquor is replenished with fresh ferrocyanide and returned to the cell. The reaction may be represented ionically as follows: $Fe(CN)_6^{\equiv\equiv}=Fe(CN)_6^{\equiv}+-$; $H_2O+-=OH^-+\frac{1}{2}H_2$.

Oxidation with chlorine is carried out by conducting gaseous chlorine into a cold 10% solution of ferrocyanide. The reaction is represented by the equation: $2K_4Fe(CN)_6+Cl_2=2K_3Fe(CN)_6+2KCl$. The passage of chlorine is discontinued when the conversion of the ferrocyanide is just completed. The solution is evaporated to the crystallizing point, a little caustic potash is added to eliminate the small amount of Prussian green formed, which is precipitated as ferric hydroxide and removed by filtration. The ferricyanide is recovered by crystallization in an 85%–90% yield.

Iron Cyanide Blues form an important group of pigments. They may be prepared directly through the interaction of ferric salts with alkali ferrocyanides or of ferrous salts with alkali ferricyanides in neutral or acid solution. They are amorphous substances containing variable quantities of combined water. Depending upon the procedure followed in their preparation, soluble or insoluble varieties may be produced. The soluble types, which may be represented by the formula $K\,Fe[Fe(CN)_6]aq.$ and contain a maximum of four molecules of water, may be prepared by mixing cold neutral solutions of ferric chloride and potassium ferrocyanide, the latter being used in excess. Insoluble blues conform to the formula $Fe_4[Fe(CN)_6]_3aq.$ and contain a maximum of 10-11 molecules of water. They are formed when an excess of a ferric salt solution is added to a neutral or slightly acid solution of potassium ferrocyanide.

Blues prepared by the direct method lack the desirable brilliancy of colour; they are generally known as Prussian blue. Fine qualities can be prepared only by an indirect process depending upon the oxidation of potassium ferrous ferrocyanide or of mixtures of this substance with ferrous ferrocyanide:

$$6K_2Fe[Fe(CN)_6]+3H_2O+3O=$$
$$Fe[Fe(CN)_6]_3+3K_4[Fe(CN)_6]+2Fe(OH)_3;$$
$$3Fe[Fe(CN)_6]+3H_2O+3O=Fe_4[Fe(CN)_6]_3+2Fe(OH)_3.$$

Paris Blue, also called Chinese blue, is the finest of iron blues. This product is made as follows: a solution of 66 kg. ferrous sulphate (120 kg. of commercial product) in 600 l. water and one of 75 kg. potassium ferrocyanide (83 kg. of the commercial product) in 1,000 l. of water are added simultaneously to 600 l. of water with vigorous agitation. The precipitate is washed by decantation, the wet paste is brought to the boiling temperature and a solution of 44 kg. ferric chloride (80 kg. of commercial product) in 200 l. of water heated to 70° C. is added in the course of one hour to one and one-half hours. The liquid is boiled with stirring for one-half hour and diluted with boiling water to 4,000 l.; the precipitate is then washed six to eight times with hot water by decantation and finally filtered and dried first at 40°–45° C. then finally at 70° C. It is important that the ferrous sulphate solution be free of ferric sulphate; sufficient purity is assured by allowing the solution to remain in contact with iron filings for one to two days.

Five main varieties of iron blues are recognized in commerce: Prussian blue, Paris blue, bronze blue, milori blue and steel blue. In chemical composition, they are nearly identical. Milori blue is a special quality, showing a bright colour and a reddish tint. It is distinguished by exceptional softness and is largely used for printing inks.

Detection and Estimation.—The presence of prussic acid in an aqueous solution may be demonstrated by a variety of methods; one that is most commonly employed depends upon the conver-

sion of the acid into Prussian blue: one or two drops of moderately concentrated sodium hydroxide solution and of freshly made ferrous sulphate solution are added to the liquid, and the whole is boiled. The liquid is cooled and acidified, and a drop of ferric chloride solution is added; a precipitate of Prussian blue then forms if prussic acid was present in the original solution. One of the most satisfactory methods for the quantitative determination of prussic acid is titration of the acid in the form of its alkali metal salt with standard silver nitrate solution, with a few drops of 10% potassium iodide solution as an indicator. The end point is reached when a permanent opalescence is observed in the solution; at this point the reaction $2NaCN+AgNO_3=NaAg(CN)_2+NaNO_3$ is just complete. It can be seen that every formula weight (*see* MOLECULE, CHEMICAL) of silver nitrate used is equivalent to two formula weights of prussic acid.

Toxic Action.—Hydrocyanic acid is highly toxic through inhibition of cellular oxidative processes. Acute poisoning from hydrocyanic acid or its salts, the cyanides, is manifested by dizziness, nausea, staggering and loss of consciousness if the amount absorbed is sufficient. Death ensues rapidly if lethal quantities are absorbed either through ingestion of the cyanides or through the inhalation of HCN gas in sufficient amounts. However, in sublethal poisoning, recovery is usually complete within a few hours and there are no permanent aftereffects. In sublethal doses the CN radical is rapidly detoxified by the body through combination with sulphur, which forms nontoxic sulphocyanides. Man can withstand 50–60 parts of HCN per 1,000,000 parts of air for 1 hr. without serious consequences while exposure to concentrations of 200–500 parts per 1,000,000 parts of air for 30 min. is usually fatal.

First-Aid Treatment for Cyanide Poisoning.—Carry patient to fresh air and have him lie down and keep warm. Call a physician. If the patient is breathing, break an amyl nitrite pearl in a cloth and hold lightly over the nose for not more than 15 sec. to 20 sec. or have him inhale aromatic spirits of ammonia. Repeat every 5 min. for 25 min. if recovery is not forthcoming. This poison is rapid in action and few patients survive.

If the patient has stopped breathing, give artificial respiration until breathing starts; then administer amyl nitrite as above.

If cyanides have been swallowed and the patient is conscious, give one pint of 1% sodium thiosulphate solution (or soapy water or mustard water) by mouth every 15 min. until vomiting occurs. Never give anything by mouth to an unconscious person. During World War II, *p*-aminopropiophenone, administered orally, was found by the medical division of the chemical warfare service, U.S. army, to have value in the prophylaxis of cyanide poisoning.

Pest Control.—The use of prussic acid for the control of insect and other pests has become quite general since D. W. Coquillet first employed the compound in 1886 for the control of scale insects of citrus trees in California. Prussic acid is extensively used as a fumigant for the control of insects in stored goods, of household pests and of insect and rodent pests occurring in ships and railways cars, and for a variety of other purposes, as well as for the control of scale insects of citrus trees and certain other agricultural pests. The liquid is available in stout steel cylinders for shipment over long distances. A product consisting of prussic acid absorbed in wood pulp disks or in granular diatomaceous earth in sealed tins is also available.

Periodic general fumigation of flour mills has become common practice in the United States. Liquid in cylinders is used for this purpose. It is sprayed at each floor from special spray nozzles attached to a permanent piping system, or to rubber hose reaching all parts of the floor. The liquid is ejected with compressed air. This method of application is also utilized in the fumigation of other large buildings and ships. The most effective and economical method of flour-mill fumigation consists in injecting the liquid into the various machines, thus producing the highest concentration of the fumigant at the sources of infestation. An elaborate permanent machinery piping system forms an essential part of this method.

The pressure of demand for effective measures directed at the prevention of insect damage to stored goods led to the development of vacuum fumigation technique. Specially constructed large cylindrical or rectangular air-tight chambers are used for this purpose. The commodities to be fumigated are introduced into the chamber on special trucks, the chambers are sealed tight and evacuated, and the prussic acid is then injected in the form of vapours. The doses required may vary, according to the commodities fumigated and the magnitude of the load, between one and one-half and three pounds or more per 1,000 cu.ft. of space.

A convenient method of fumigation of dwelling houses and commercial establishments of moderate size utilizes disks of wood pulp impregnated with liquid prussic acid. The disks are contained in sealed metal cans which are opened just before use by means of a special cutter. The disks are evenly scattered throughout the various floors of the building on heavy paper placed on the floor.

The introduction of calcium cyanide made possible the satisfactory solution of a number of difficult pest control problems. It has already been pointed out that the mode of action of this product depends upon its reaction with the moisture contained in the atmosphere, generating vapours of prussic acid. Calcium cyanide in the finely ground form is the most effective agent known for the destruction of burrowing animals such as rats, rabbits, ground hogs, etc. It is also one of the best fumigants for the control of ants and termites in their nests. In areas where liquid hydrocyanic acid is not locally available, calcium cyanide is used successfully for the control of the scale insects of citrus trees. Calcium cyanide is used as a fumigant for the destruction of aphids and other sucking insects in greenhouses. A granular form is best suited for this purpose; it is applied on the walks in a thin layer in quantities corresponding to one-eighth ounce to one-fourth ounce per 1,000 cu.ft. of space. Application is begun an hour after sunset and the house is allowed to remain closed overnight. The temperature within the house should be rising and preferably between 60° F. and 70° F., and the air should be calm. Several applications at weekly intervals are recommended.

An important use of calcium cyanide is the fumigation of grain in storage, for which a granular form of the product is used. It is applied to the grain at a controlled rate by a special device at the time the grain is run into the bin. A dosage of 10 lb. to 20 lb. per 1,000 bu. of wheat gives satisfactory control of insects without damage to the grain.

Casehardening.—Casehardening of iron or steel articles by immersion in a fused cyanide bath came into general use, especially in the United States and Canada, after its introduction in 1910. The bath material usually consists of 60% sodium cyanide mixed with other salts such as sodium carbonate or sodium chloride. It is fused in mild steel or chromium-steel pots and the temperature is raised to a point above 760° C. The cyanide gradually decomposes and the resulting carbon combines with, and penetrates into, the metal.

The rate of penetration of carbon into mild steel is about 0.01 in. per hour and about 50% greater when nickel steel is used. Casehardening usually implies a case depth of 0.015 in.–0.060 in.; cases of smaller depth, in some instances only 0.005 in. thick, are produced for surface hardening.

Sodium cyanide is added to heat-treating baths to prevent decarburation of the treated pieces. A concentration of 10% is usually regarded sufficient for this purpose, but lower or higher concentrations may be used in connection with low and high carbon steels.

Electroplating.—A solution containing the double cyanide of sodium and silver, $NaAg(CN)_2$, or the corresponding potassium salt, and a molecular excess of the alkali cyanide serves for electroplating metal articles with silver. The article to be plated, its surface thoroughly cleaned, and a sheet of silver are suspended in the solution a few inches apart; and a direct current is passed through at a rate of three amperes per square foot of surface. The article to be plated is made the cathode, the silver the anode. As electrolysis proceeds, the silver anode gradually dissolves, and an equal quantity of the metal is deposited out of the solution upon the surface of the article. The concentrations of the double salt commonly used correspond to two ounces to four ounces silver per imperial gallon. The solution improves with use. Plating with gold, gold-silver or gold-copper alloys is done in a similar way.

Cyanide solutions are also used in deposition of copper, zinc, brass and cadmium, more especially on iron.

Flotation.—In the flotation process of ore concentration, separation of metal sulphides is effected by a rising current of air bubbles through the vigorously agitated water suspension of the ore containing a little oil or other flotation agents. The metal sulphides rise with the froth and are obtained in a concentrated form by collecting the froth. G. E. Sheridan and G. G. Griswold discovered in 1922 that the addition of a small amount of sodium cyanide to the suspension of ore previously made faintly alkaline with soda ash prevents the flotation of zinc and iron sulphides without affecting that of lead and copper sulphides. By making use of this effect the sulphides of zinc and iron may be separated from those of lead and copper. The iron and zinc sulphides may be separated by a second treatment in more strongly alkaline solution, the zinc alone floating.

Sodium and calcium cyanides are used extensively in the process of gold and silver extraction. (*See* CYANIDE PROCESS.)

PRUTZ, HANS (1843–1929), German historian, son of Robert Eduard Prutz (1816–1872), the essayist and historian, was born at Jena on May 20, 1843, and studied at Jena and Berlin. His *Preussische Geschichte* (4 vols., Stuttgart, 1899–1902) is an attempt to apply scientific rather than patriotic canons to a subject which has been mainly in the hands of historians with a Prussian bias. In 1902 Prutz resigned the chair of history in the university of Königsberg, which he had held since 1877.

His other works include: *Aus Phönicien,* a collection of historical and geographical sketches (1876); *Quellen-beiträge zur Geschichte der Kreuzzüge* (1876); *Kulturgeschichte der Kreuzzüge* (1883); *Staatengeschichte des Abendlandes im Mittelalter* (1885–87); *Geheimlehre und Geheimstatuten des Tempelherrenordens* (Danzig, 1879); *Entwickelung und Untergang des Tempelherrenordens* (1888); *D. geistl. Orden,* (1907).

PRYNNE, WILLIAM (1600–1669), English parliamentarian, son of Thomas Prynne, born at Swainswick near Bath, was educated at Bath Grammar School and at Oriel College, Oxford. He was called to the bar at Lincoln's Inn in 1628. He was Puritan. In 1629 Prynne came forward as the assailant of Arminianism in doctrine and of ceremonialism in practice, and thus drew down upon himself the anger of Laud. *Histrio-mastix,* published in 1633, was a violent attack upon stage plays in general, in which the author pointed out that kings and emperors who had favoured the drama had been carried off by violent deaths, and applied a disgraceful epithet to actresses, which, as Henrietta Maria was taking part in the rehearsal of a ballet, was supposed to apply to the queen. After a year's imprisonment in the Tower Prynne was sentenced by the star chamber on Feb. 17, 1634 to be imprisoned for life, and also to be fined £5,000, expelled from Lincoln's Inn, rendered incapable of returning to his profession, degraded from his degree in the university of Oxford, and set in the pillory, where he was to lose both his ears. The latter portion of the sentence was carried out on May 7, and the rest of his punishment inflicted except the fine and part of the imprisonment. There is no reason to suppose that his punishment was unpopular.

In 1637 he was once more in the star chamber, together with Bastwick and Burton. In *A Divine Tragedy lately acted* he had attacked the Declaration of Sports, and in *News from Ipswich* he had assailed Wren and the bishops generally. On June 30 a fresh sentence, delivered on the 14th, was executed. The stumps of Prynne's ears were shorn off in the pillory, and he was branded on the cheeks with the letters S.L., meaning "seditious libeller," which Prynne, however, interpreted as "*stigmata laudis.*" He was removed to Carnarvon Castle, and thence to Mont Orgueil Castle in Jersey, where he occupied himself in writing against popery.

Immediately upon the meeting of the Long Parliament in 1640 Prynne was liberated. On Nov. 28 he entered London in triumph, and on March 2, 1641, reparation was voted by the Commons, at the expense of his persecutors. Prynne now attacked the bishops and the Roman Catholics and defended the taking up of arms by the parliament. He showed a vindictive energy in the prosecution of Archbishop Laud. He manipulated the evidence against him, and having been entrusted with the search of Laud's papers, he published a garbled edition of the archbishop's private "Diary," entitled *A Breviate of the Life of Archbishop Laud.* He also published *Hidden Works of Darkness brought to Light* in order to prejudice the archbishop's case, and after his execution, *Canterbury's Doom . . .* an unfinished account of the trial commissioned by the House of Commons. Prynne supported a national church controlled by the state, and issued a series of tracts against independency. He denounced Milton's *Divorce at Pleasure,* was answered in the *Colasterion,* and contemptuously referred to in the sonnet "On the Forcers of Conscience." He also opposed violently the Presbyterian system, and denied the right of any Church to excommunicate except by leave of the state (e.g., *Four Short Questions* [1645]; *A Vindication of Four Serious Questions* [1645]). He was throughout an enemy of individual freedom in religion.

Prynne took the side of the parliament against the army in 1647, supported the cause of the eleven impeached members, and visited the university of Oxford as one of the parliamentary commissioners. In 1648 Prynne was returned as member for Newport in Cornwall. He at once took part against those who called for the execution of Charles; the result was his inclusion in "Pride's Purge" on Dec. 6, when, having resisted military violence, he was imprisoned. After recovering his liberty Prynne retired to Swainswick. On June 7, 1649, he was assessed to the monthly contribution laid on the country by parliament. He not only refused to pay, but published *A Legal Vindication of the Liberties of England,* arguing that no tax could be raised without the consent of the two houses. He was imprisoned in various places from 1650 to 1653, and on his release renewed his pamphleteering activities.

On the restoration of the Rump Parliament by the army of the 7th of May 1659 fourteen of the secluded members, with Prynne among them, claimed admittance. He was prevented from taking his seat, and a second attempt in December also failed. He was returned for Bath to the Convention parliament and to the parliament of 1661. During 1663 he served constantly on committees, and was chairman of the committee of supply in July, and again in April 1664. The last time he addressed the House appears to have been in Nov. 1667.

Prynne died unmarried, in his lodgings at Lincoln's Inn, on Oct. 24, 1669, and was buried in the walk under the chapel there.

PRYOR, ROGER ATKINSON (1828–1919), U.S. soldier and jurist, was born near Petersburg, Va., on July 19, 1828. He graduated at the law school of the University of Virginia in 1848, and in 1849 was admitted to the bar. He served as a Democrat in the National House of Representatives, 1859–61, and was re-elected for the succeeding term, but owing to the secession of Virginia did not take his seat. He served in the provisional Confederate congress (1861) and also in the first regular congress (1862) of the Confederate constitution. He entered the Confederate army as a colonel, became a brigadier-general (April 16, 1862), and took part in the battles of Williamsburg, Seven Pines, second Bull Run and Antietam. Owing to a disagreement with President Davis he resigned his commission in 1863, and entered Gen. Fitzhugh Lee's cavalry as a private. He was taken prisoner Nov. 1864, but was released on parole by order of the president. In 1865 he removed to New York city, where he practised law. He was judge of the New York court of common pleas, 1890–94, and of the New York supreme court, 1894–99, when he retired from the bench. He died in New

York city on March 14, 1919.

PRYTANEUM AND PRYTANIS. 1. In ancient Greece, each State, city or village possessed its own central hearth and sacred fire; the fire (*cf.* at Rome the fire in the temple of Vesta) was kept alight continuously, tended by the king or members of his family. The building in which this fire was kept was the Prytaneum (Πρυτανεῖον), and the chieftain (the king or prytanis) probably made it his residence. The word prytanis is applied to those who, after the abolition of monarchy, held the chief office in the State. Rulers of this name are found at Rhodes as late as the 1st century B.C. The Prytaneum was regarded as the religious and political centre of the community. When colonists went out they took with them a brand from the Prytaneum altar to kindle the new fire in the colony; the fatherless daughters of Aristeides, regarded as children of the State at Athens, were married from the Prytaneum as from their home; foreign ambassadors and citizens who had deserved especially well of the State were entertained in the Prytaneum as public guests. In Achaea, this central hall was called the *Leïton* (town-hall), and a similar building is known to have existed at Elis. The site of the Prytaneum at Athens cannot be definitely fixed. The Prytaneum mentioned by Pausanias, probably the original centre of the ancient city, was situated somewhere east of the northern cliff of the Acropolis. Curtius places the original Prytaneum south of the Acropolis in the old Agora, and regards that of Pausanias as a building of Roman times (*Stadtgeschichte,* p. 302). Many authorities hold that the original Prytaneum of the Cecropian city must have been on the Acropolis. From Aristotle's *Constitution of Athens* (ch. 3) we know that the Prytaneum was the official residence of the archons, but, when the new Agora was constructed they took their meals in the *Thesmotheteion* for the sake of convenience. There was also a court of justice called the court of the Prytaneum; it tried murderers who could not be found, and inanimate objects which had been the means of causing death.

2. For the PRYTANEIS of the Boulē *see* BOULE.

PRZEMYSL, a town of Poland, in the province of Lemberg (Lwow), 60 mi. W. of Lwow by railway. Pop. (1931), 51,379, mostly Polish. It is situated on the river San, and is the seat of a Roman Catholic and a Greek Catholic bishop, the cathedral dating from the 15th century. The industries comprise the manufacture of machinery, the refining of naphtha, corn-milling and the sawing of timber. On the hill above the town are the ruins of an old castle, said to have been founded by Casimir the Great.

Przemysl was founded at an early date on the borderland between Poland and Russia. Russian princes founded a state there in the 11th century, which became absorbed in the principality of Galich or Halicz and was annexed by Casimir the Great after 1340. It was occupied by Austria from 1773 to 1915. Polish after 1918, it was occupied by the U.S.S.R. in 1939 and Germany in 1941.

PRZEMYSL, SIEGES OF. In 1914 Przemysl was protected by a ring of forts 36 m. in circumference. Some of the forts were of recent construction, but the fortress as a whole was not strictly up-to-date. To clear the foreground in front of the fortified line no fewer than 18 villages and some five miles of forest were levelled to the ground on mobilization. The armament of the fortress included four large modern howitzers of about 12in. calibre and some 9in. and 6in. howitzers of older pattern. There were in all about 1,000 guns in the fortress, but more than half of these were old, short-range weapons of little value except for close defence. There were 114 machine-guns, of which two-thirds were mobile.

The eventual garrison left in the fortress when the Austrian armies retreated from the San on Sept. 18, 1914, consisted of: 61½ battalions (of which 40½ were Landsturm), seven squadrons, four field batteries, 43 fortress artillery companies, 48 Landsturm artillery brigades, eight sapper companies, and various technical and administrative units. The total strength was approximately 130,000 men and 21,000 horses. Provisions were available for three months.

The First Siege.—The Austrian armies withdrew from the San on Sept. 18; by Sept. 24 the investment of the fortress was complete. On the south-west front the garrison held a line a mile or two in advance of the ring of forts; elsewhere the line of the forts was held. The siege of the fortress was undertaken by Radko-Dimitriev's III. Army. While the arrival of the siege artillery material was still delayed by the state of the communications, the Austrians renewed the offensive in the early days of Oct. (*see* VISTULA-SAN, BATTLES OF THE). In the hope of capturing Przemysl by a *coup de main* before the progress of the enemy offensive compelled the raising of the siege, Radko-Dimitriev carried out several violent assaults between Oct. 5–8 against the Siedliska group of works to the south-east of the town. These assaults broke down with heavy loss, and the approach of the Austrian III. Army necessitated the withdrawal of the investing forces. The fortress was entered by Austrian infantry of the field armies on Oct. 11, on which date Radko-Dimitriev's III. Army retreated to the east bank of the San.

Period Between the First and Second Sieges.—During the Austrian attempts to force the San line, which lasted throughout October, the fortress lay in the centre of the battle line and its garrison took an active part in the operations. Its reserves of supplies and material were also largely drawn on by the field armies to make good the deficiencies caused by the poor working of the lines of communication. During their retreat the Russians had systematically destroyed the railways and bridges, and the continued wet weather had rendered the roads almost impassable. Thus it was natural that the reserves of Przemysl should be used for the benefit of the field armies, from whose operations great results were expected at the time. But when the offensive proved fruitless and Russian pressure necessitated a retirement which would leave the fortress again isolated, special efforts were made hastily to reprovision it. They were so far successful that the fortress was enabled to hold out for 4½ months in the second siege.

Second Siege, Nov. 6, 1914–March 22, 1915.—The strength of the garrison was approximately the same as in the first siege, but a detachment of aeroplanes had been added. Kusmanek had now laid out new entrenched positions from one to two miles in advance of the line of forts, to give more depth to the defence and to keep the Russian siege artillery at a greater distance. On Nov. 9 the investment of the fortress for the second time was complete. The siege was now undertaken by a specially formed XI. Army under General Selivanov, consisting of four divisions of second-line troops. It had been decided to reduce the fortress by blockade rather than by assault. During November and December such fighting as occurred was initiated rather by the sorties of the garrison than by the attacks of the besiegers.

During February and the first half of March the Austrian field armies made repeated efforts to advance to the relief of the fortress, but unsuccessfully (*see* CARPATHIANS, BATTLES OF THE). Meanwhile the Russians had gradually closed in and had commenced a systematic bombardment of the fortress. On March 13 they carried the advanced positions on its north front. Kusmanek's situation was now desperate; his supplies and munitions were almost exhausted, and the final effort of the field armies to come to his rescue had definitely been abandoned. He determined on an attempt to save a portion of the garrison by a break-through to the east. The effort was made on the morning of the 19th, but was soon brought to a stand. The fate of the fortress was now sealed. On the morning of March 22 Kusmanek surrendered, after destroying the works and military stores as far as possible. The numbers of the garrison then amounted to about 110,000.

Recapture of the Fortress.—The Russians did not hold the fortress for long. At the beginning of May Mackensen's offensive on the Dunajec broke through the Russian line and drove their armies back to the San (*see* DUNAJEC-SAN). On May 30 the

Austrians attacked on the south-west and the Germans on the north of the fortress. The former made little progress, but the German heavy artillery, which included 42 cm. howitzers, made short work of the northern group of forts. On the night of June 2 the Russians abandoned the fortress.

Conclusions.—Przemysl was the only land fortress of World War I which stood a prolonged siege after complete investment, but the length of its resistance was seemingly due to the Russians' lack of efficient siege artillery, as is confirmed by the speed with which Mackensen's heavy guns reduced the forts at the time of its recapture. Nor can it be admitted that the fortress served any strategical aim commensurate with the efforts expended on its defense and attempted relief. It is true that its resistance during the first siege was of value to the Austrians when their armies again advanced to the San, in assuring to them a bridgehead over the river. But during the second seige Przemysl was an embarrassment rather than a source of strength and led to several ill-considered efforts at relief which cost the Austrian field armies dearly. The fortress did not control any line of supply vital to the Russian armies operating west of it toward Cracow, since there was a railway available through Jarostow. The Russians could therefore afford in the second siege to resort to a simple blockade by second-line troops, so that the fortress did not even weaken their field armies to any appreciable extent.

PRZHEVALSK: *see* KARAKOL.

PSALMANAZAR, GEORGE (*c.* 1679–1763), French adventurer. After various escapades, including a pilgrimage to Rome in the guise of a Japanese convert, he came to London, where he imposed on many people, notably on the bishop of London, who employed him to translate the Catechism into what was supposed to be Japanese. In 1704 and 1707 he published fictitious works on Formosa. Eventually he confessed to his imposture. He died in London on May 3, 1763. His memoirs, *Memoirs of . . . commonly known by the name of George Psalmanazar* (1764) do not disclose his real name or the place of his birth. His fictitious publications include: *Historical and Geographical Description of Formosa* (1704); *Dialogue between a Japanese and a Formosan* (1707); *An Enquiry into the Objections . . . with George Psalmanazar's Answer* (undated).

See P. W. Sergeant, *Liars and Fakers* (London, 1926).

PSALMS, the first in order and importance (*cf.* Luke xxiv. 44) of the third division of the Hebrew Old Testament, known as the "Writings." The Hebrew name of the Psalms is *tehillim,* or "praise-songs," which expresses a predominant, though by no means the entire, character of the collection. This anthology of Hebrew poetry also includes petitions (iv.), laments (xliv.), imprecations (lviii.), meditations (cxix.), historical reviews (cvi.), and even a marriage ode (xlv.). But there can be no doubt that the purpose of the collection was to gather the sacred poetry of Israel for use in the *post-exilic* worship of the temple. This is shown by the technical and professional titles of the psalms, as well as by their general character and their occasional references (note the definite allusions to the destruction of Jerusalem, the exile or the dispersion in li. 18, lxxxix. 38, 44, cvi. 47, cxxvi. 1, cxxxvii. 1, cxlvii. 2).

As the book lies before us, it is a collection of collections, being divided into five books, which themselves contain certain smaller distinguishable groups of psalms. The first four books are each closed by a doxology, at least as old as the Septuagint version (second half of 2nd century B.C.). In Bk. I. (i.–xli.) practically all the psalms are ascribed to David (the exceptions can be explained). In Bk. II. (xlii.–lxxii.) there is more variety, xlii.–xlix. being ascribed to "the sons of Korah," l. to Asaph, li.–lxv. to David, lxvi., lxvii. simply to "the chief musician" or choir-conductor, lxviii.–lxx. to David, lxxii. to Solomon (lxxi. is anonymous). The editorial note at the end of this book, "Finished are the prayers of David the son of Jesse," shows there was once a collection of "Davidic" psalms, and that there has been a rearrangement of material bringing psalms of other groups above the rubric. In Bk. III. (lxxiii.–lxxxix.) there is an "Asaph" group (lxxiii.–lxxxiii.) followed by a miscellaneous appendix (Korah, David, Ethan). We have clear evidence of other editorial work in the overwhelming predominance of the name "Elohim" for God in Psalm xlii.–lxxxiii. as compared with the personal name, "Yahweh" (the occurrences are 200:43; in Psalms, i.–xli. 15:272); this is confirmed by the fact that Ps. xiv. of the first Book reappears as Ps. liii., with its fourfold "Yahweh" changed into "Elohim" (so also in Pss. xl. 13–17 and lxx.). In Bks. II. and III. alone do we get psalms ascribed to guilds of temple-singers. Bks. IV. and V. are divided by the doxology of cvi. 48 (*cf.* 1 Chron. xvi. 35, 36, where a liturgical formula has been transformed into a historical statement). But the division seems artificial (perhaps made to get five books of psalms corresponding with the five books of the law), since Psalms cv.–cvii. are closely related in subject-matter. If, therefore, we take Bks. IV. and V. together, we find in them a distinct group of "Pilgrim" psalms (cxx.–cxxxiv.), and a scattered one of "Hallelujah" psalms (civ.–cvi., cxi.–cxiii., cxv.–cxvii., cxxxv., cxlvi.–cl.) largely liturgical. Ps. cviii. seems to have been made by combining lvii. 7–11 and lx. 5–12, which again proves the existence of separate collections, since the same material would not originally appear twice in the same collection.

The Hebrew psalms are in rhythmical, but unrhymed verse, the most frequent type being that of the three-beat line. The other characteristic of Hebrew poetry is its parallelism ("synonymous," li. 2; "antithetic," i. 6; "synthetic," cxxi. 4). The musical accompaniment was melodic unison, not the harmonies of modern music, so that its chief use, beyond support to the singers, was to synchronize the beats, as by cymbals (1 Chron. xv. 19, xvi. 5). Six distinct instruments are named in Ps. cl. (*see* Wellhausen, *Psalms,* Appendix, "Music of the Ancient Hebrews"). The singing was by professional choirs with a response ("Amen," "Hallelujah") from the worshippers (1 Chron. xvi. 36, 2 Chron. xxix. 27, 28). For a glowing description of the ritual *see* Ecclus. l. 11–21.

At first sight, the contents of the Psalter may seem to occasion relatively little difficulty to the exegete, as compared with the prophecies. The psalms are for the most part simple and often conventional in language, and without those references to obscure historical events which make the writings of the prophets so difficult. But the apparent gain is really a great loss to historical exegesis. Whilst the absence of reference to contemporary events makes the psalms much more capable of use then than now in worship and devotion—it was in some measure due, we may suppose, to elimination and adaptation—yet it also makes the investigation of the original meaning more difficult. Thus it is usually impossible to give a precise historical background to a particular psalm. The titles professing to do this, and to ascribe authorship, are of little use for critical purposes, and represent a late and usually worthless conjecture. Scholars have now generally abandoned the earlier attempts to ascribe particular psalms to precise events from the Davidic down to the Maccabean age; there is considerable variety of opinion as to the nature, date, authorship and origin of the psalms considered individually.

Four main questions arise: (1) to what extent are the psalms primarily and originally "cultic," more or less officially composed for use in public worship, and to what extent are they private religious lyrics, gathered from many sources, and subsequently adapted to use in the temple-services? (2) In close relation with this question comes another as to the significance of the speaker in many of the psalms; does the "I" mean the whole community, or is it an individual person who is speaking? (3) To what period of the religious history of Israel do the psalms chiefly belong, and to what extent are they pre-exilic in origin, though admittedly post-exilic in present adaptation and arrangement? (4) Are they a native product or are they dependent on Babylonian or Egyptian models, as the creation stories of Genesis are dependent on Babylonian mythology? It will be seen that these are not merely academic questions, for each of them may affect the exegesis of

a particular psalm. A quarter of a century ago, the answers to these four questions generally given by critical scholarship were as follows: (1) the psalms are chiefly poems of the individual, though some were intended from the outset for use in the temple; (2) the "I" of the psalms usually represents the community; (3) the psalms are almost wholly post-exilic in origin; (4) they are native products. All these answers are now being met with vigorous criticism. At the present moment the protagonists in this criticism are the German scholar, Gunkel, and the Norwegian scholar, Mowinckel. Some account of their views must be given, as they cannot be neglected by the modern student of the psalms.

Gunkel's leading principle is that the psalms should be studied in their "classes" (*Gattungen*) or types, of which he finds four of chief importance, viz., "hymns" (*e.g.*, cxlv., cxlvii., cxlviii., cl.), "national laments" (*e.g.*, xliv., lxxix., lxxx., lxxxiii.), "individual laments" (iii., xiii., liv., lxxxviii.) and "individual thanksgivings" (xxx., lxvi., 13 *seq.*). These classes are differentiated by the use of regular formulae, such as "Deliver us, Yahweh," or "I will thank Yahweh," and by more or less regular forms of composition, so that we are not left to subjective impressions only when deciding as to what class a particular psalm belongs. On the basis of this differentiation Gunkel constructs a general history of the "classes," partly from internal evidence, such as the greater length, individualization, or composite character of the later representatives of the class, and partly from the parallels with psalm-like compositions found elsewhere in the Old Testament, which it is possible to date with confidence, such as the Song of Miriam (Exod. xv. 21), the song of the seraphim heard by Isaiah in the temple (vi. 3), the lyrics of Jeremiah and the "Psalms of Solomon" (1st century B.C.). Gunkel's general conclusion is that hymns of praise and national laments were found at an early date, whilst individual laments arose later, but *prior* to Jeremiah. He admits that prophecy influenced the language, eschatological outlook and spirituality of the Psalms, but claims that this influence was exerted before as well as after the exile. He argues that the existence of similar compositions in Babylonia and Egypt at a much earlier date confirms the intrinsic evidence that "Psalm-composition belongs to the earliest periods of Israel's history."

Mowinckel, whilst recognizing and using the classification of psalms by their type, throws his emphasis on their cultic character, and indeed barely admits the existence of any psalms not cultic in origin (his exceptions are i., cxii., cxxvii.). The psalms were composed by the temple-singers, whom he regards as existing from the early days of the temple. The class of psalms to which he gives primary attention is that containing references to the enthronement of Yahweh as king (xlvii., xciii., xcv.–c., with which many others are to be linked). These he connects with an alleged festival of the New Year (originally beginning in the autumn), a festival after the analogy of that celebrated at Babylon in honour of Marduk. The cultic acts of this festival (*e.g.*, the procession bringing the ark into the temple) were realistically conceived, *i.e.*, they were supposed to help in bringing about that which they "dramatized." Thus they anticipated the future (eschatology) while recalling the past (mythology). There is a similar "realism" in Mowinckel's interpretation of the numerous petitionary psalms, which are held to attribute misfortune and sickness to magicians and sorcerers, who are the original "workers of iniquity" so frequently mentioned. Such psalms were employed, with suitable accompanying rites, as part of the temple-cult; they counteracted adverse magic by exorcisms and imprecations of these "enemies." There were prophets as well as priests, or priest-prophets, attached to the temple, who gave oracles; thus the petition of Ps. lxxxv. 1–7 is answered by the oracle of vv. 8–13. It should be said that a "cultic" interpretation of the psalms as a whole has been independently urged by other scholars, *e.g.*, by J. P. Peters, who further conjectures that the "Elohistic" psalms belonged to northern temples (*cf.* the northern "Elohistic" saga-writers), the Korahite to Dan, the Asaphite to Bethel, and were afterwards incorporated in the liturgy of Jerusalem.

It will be seen, therefore, that there is considerable division of opinion at the present time in regard to our first question, the cultic element in the Psalter, Mowinckel regarding practically the whole Psalter as cultic in origin, whilst Gunkel regards the majority of the psalms as of private and occasional origin, though subsequently introduced into the cult. On this point Gunkel's view seems more convincing, from the intrinsic evidence and from the general probabilities. Like a modern hymn-book, the Psalter seems to contain many poems not originally intended for use in worship, but subsequently adapted to it—indeed, the religious wealth of the Psalter seems largely due to this variety of origin. On the other hand, Mowinckel does make a strong case for the special interpretation of the psalms of the enthronement of Yahweh, even though he brings far too many under this head. His explanation of the "eschatological" features is also attractive; less so seems his too sweeping connection of sickness and misfortune with magic, though there is probably an element of real truth in his contentions (the tendency of those who discover some neglected truth is to generalize to excess on the basis of it). In a collection so extensive and varied as the Psalter we need not regard any one explanation or theory as necessarily applicable to more than a part of the material. Variety of origin almost follows from variety of date, and their issue is most naturally variety of meaning, even where the same conventional phrases may be used.

In regard to the closely linked question as to the collective or individual interpretation of the speaker in the psalms, Gunkel follows Balla in reaction from the view that was general a quarter of a century ago (*e.g.*, Smend, Cheyne), *i.e.*, that the "I" of the Psalms is collective, personifying the nation. Mowinckel agrees with Gunkel so far as the "individual laments" are concerned, but recognizes a primitive "corporate personality" finding utterance through the leader or king as its representative. We may ask whether this principle does not admit of a wider application than even Mowinckel allows. It seems to go a long way towards explaining the puzzling combination of "collective" and "individual" elements in such a psalm as the xxii., and the rapid transitions so often found (*cf.* xliv. 5–7 and 14, 15). The same phenomena occur in relation to the Servant of Yahweh in Deutero-Isaiah, and admit of the same explanation—that the primitive mind draws no such hard and fast limits between the individual and the community as we do (see *The Cross of the Servant*, by H. Wheeler Robinson, pp. 32–36; *The Psalmists*, ed. D. C. Simpson, pp. 82 *seq.*). We may often find it impossible to decide whether a psalm is collective or individual—because the ancient category was neither one nor the other, but a third category including both.

In regard to dating the composition of individual psalms, there seems to be some danger of a similar excessive reaction from the view associated with the name of Wellhausen, open as that is to criticism. The arguments of Gunkel and Mowinckel, amongst others, do show in their different ways that psalms were composed in the pre-exilic period, a fact which has been too grudgingly admitted. The intrinsic evidence of some of the psalms, such as the reference to a human king, or the processional features of the second part of xxiv. ("Lift up your heads, O ye gates"), or the primitive cosmology of the first part of xix., confirms the probability that some of these pre-exilic productions would survive in a post-exilic Psalter. So long as we are thinking of the origin and original meaning of a particular psalm, we must always be prepared to admit that it may go back to a relatively early date, however much modified in its present adaptation to the needs of the second temple. On the other hand, we use any psalm in its present form as an early document only at considerable risk; we may conjecture, but we cannot prove. The main reasons for regarding the contents of the Psalter as largely post-exilic remain unaffected by recent criticism, *i.e.*, those that spring from the general relation of the religion of the psalms to the prophetic religion. If with Gunkel we regard the majority of the psalms as the expression of individual piety, we have to ask whether such wide-spread piety is conceivable before the work of the great prophets. The psalms represent a partial fulfilment of the prophecy of the New Covenant made by Jeremiah; is it likely that they preceded it? We cannot reasonably doubt

that the prophets of the 8th and 7th centuries were pioneers, and that they taught truths that were new to their contemporaries, even though they may have used forms of expression and even of thought which were more or less conventional. Nor can there be any doubt that the religion of the Psalter as a whole is closely related to the prophetic teaching. We seem to have parallel phenomena in the formulation of Israel's laws (Deuteronomy, the Law of Holiness, the Priestly Code) and in the Wisdom Literature; in all three cases ancient elements are given a new setting, but the new setting gives them a new meaning. Laws, proverbs and psalms are alike reinterpreted and restated in the light of the prophetic teaching, which had certainly taken time to permeate the nation's religion. Nothing has come to us through the editorial sieve that could not be given a plausibly orthodox meaning according to post-exilic standards. Thus the psalms as a whole must still be treated as a post-exilic book. This might be confirmed by the subtler test of psychological usage, hardly to be simulated; the word "spirit," for example, is used of man in the psalms with psychical predicates in a way not found elsewhere in the pre-exilic literature of the Old Testament.

As for the relation of the psalms to the similar compositions of Babylonia, we find many interesting and instructive parallels of form, language and thought, but not less striking differences which must not be ignored, due to the far higher religious standpoint of Israel, and the suppression of magic in the interests of religion (though some of the older forms and expressions doubtless continued to be used). The resemblances may be partly explained by the independent development of closely related peoples (G. R. Driver, in *The Psalmists*, pp. 109 *seq.*), and partly by the entrance of the Hebrews into a land dominated by Mesopotamian influence (as the Tell el-Amarna tablets prove); but it is quite possible that there was some direct influence also, even prior to the exile. This possibility also applies, but in a much smaller degree, to the influence of Egypt; there is the well-known parallelism of the "Hymn to the Sun" of Ikhnaton with Ps. civ., which matches the close relation of the "Teaching of Amenophis" to our canonical Book of Proverbs. But whatever contributions came directly or indirectly from without, there is good ground for holding that in all that really matters the Psalter is a native product, and that to Israel still belongs the undiminished glory of carrying the religious lyric to its highest point of development.

Any attempt to characterize the teaching of this anthology must be made with the full consciousness of its variety of authorship, purpose and date. It is the most varied of the books of the Old Testament, and offers many unreconciled antitheses. Devotion to the sacrificial system and ritual of the temple is found side by side with prophetic protests against the popular reliance on them. Faith in the exact retributive justice of God within the limits of earthly life does not exclude the perplexities of those who could not be blind to the sufferings of the innocent and the prosperity of the wicked. The nationalistic demand for supremacy over, and even for vengeance on, enemies is neighbour to the universalistic sense of Israel's missionary stewardship for all the world. The recoil from the shadow of death, which leaves no light of Yahweh's presence beyond the grave, does not wholly prevent the conviction of a fellowship with God that virtually conquers death. But certain comprehensive truths may be usefully remembered in the study of the Psalms.

The central religious principle is, of course, the idea of God. The monotheism is sometimes implicit rather than explicit, for there are a number of references to other "gods" (lxxxvi. 8, lxxxix. 6, xcv. 3, etc.); yet these are perhaps no more than the survival of ancient phraseology. The general standpoint of the psalms is that of an exalted and imageless monotheism (cxv.), unlimited in power, universal in range. The most prominent attributes of Yahweh are "lovingkindness" (*chesedh*) and "righteousness" (*ṣedheḳ, ṣedhaḳah*), combined in cxlv. 17, expanded in xxxvi. 6–11; they are complementary, not antithetical. To these must be added the mystery and majesty of God—the quality which we have come to call "the numinous," best expressed in Ps. xc.; the wrath of God cannot be measured by human norms of right and wrong. This great God is omnipresent (cxxxix. 7–12), and eternal (xc. 1, 2; cii. 26–28). Around this great and exalted personal centre in heaven, but on the lower level of earth, we may trace a series of concentric circles in nature, history, human society, the temple, narrowing at last to the personal religion in which man can look right up to God. Nature is directly controlled in all its detail by God, and no "laws of nature" come between Him and His creation. The cosmology of the "nature" psalms (viii., xix. 1–6, xxix., lxv., civ., cxlviii.) is crude; man walks on a flat earth, with the "shades" of Sheol beneath his feet, and Yahweh with His angels above his head, on the solid firmament; round about the earth is the primaeval ocean and its monsters, overcome long since by Yahweh's creative power. The great facts which emerge from this primitive setting of man's life are the dignity and glory of his high place (viii.) amid the glories of Yahweh's creation (xix. 1–6) and His universal providence (civ.). The power of the enthroned Yahweh is manifest in the majesty of the thunderstorm which sweeps the earth, whilst in the heavenly palace His angels glorify Him (xxix.).

The peculiar providence of God is, however, best seen in the redemptive history of Israel (lxxxi. 10). At great crises, Yahweh has intervened to save His chosen people (cxiv.). The God of the past (cv., cvi.) will be the God of the future, when His rule shall be proved supreme over all (xlvii., and the other "enthronement" psalms). A prince of the house of David shall be his vicegerent (lxxxix. 35 *seq.*; *cf.* ii., lxxii.) and the final judgment of men shall vindicate His righteousness (i. 5). This is the essential faith of the righteous, the company of those who fear Yahweh and are remembered by Him (*cf.* Mal. iii. 16), the group to whom we seem to owe the most "spiritual" of the psalms. They live in a society of mingled elements, and have many enemies, without and within, for there are imprecations against unworthy Israelites (lxix., cix.) as well as against the ungodly heathen (cxxxvii., lxxxiii., lix., lviii.), and they may be under unjust rulers (lii.). Their great problem is that which troubled the best minds and hearts of Israel, and found no solution within the Old Testament, *i.e.*, the strange and perplexing prosperity of the wicked and the adversity of the righteous in a world governed by an omnipotent and righteous God (xlix., xxxix., xxxvii., lxxiii.).

The sacramental centre of this faith is the Temple in Jerusalem, to which the exile turns with passionate longing (xlii., xliii.—originally a single psalm). (The devotion to the "Law" came later, except for i., xix. 7–14, cxix.) To the temple come the pilgrims from afar (cxx.–cxxxiv.), full of pride in the holy city (xlviii.), the spiritual home of many proselytes as well as of Jewish exiles (lxxxvii.). The temple is Yahweh's earthly dwelling-place (cxxxii. 13, 14) to which His "guests" may come (xv., xxiv.); its sacrifices (lxvi. 13–15, cxvi. 13) and processions (lxviii. 24–27, cxviii., xxvi. 6) mark supreme moments of religious experience. This is the normal attitude of the Psalmists towards the temple; but the emphasis of the Book is prophetic rather than priestly, and this finds utterance sometimes in the contrast of "spiritual" religion with external rites (xl., l., li., except for the added verses, li. 18, 19). The personal religion of the psalmists is marked by trust in Yahweh based on history and experience (xvi., xxiii., xci., ciii.), by the consciousness of "righteousness" (xviii. 20–24), not divorced from fundamental ethical qualities (xv., xxiv., ci., l.), by the awakening to a sense of sin and of the need of forgiveness, usually, it would seem, through misfortune, sickness, the fear of death (xxxii., li., cxxx.), and in the highest examples, by a victorious conviction of fellowship with God (lxxiii. 23–26) which even death will not be able to break. This last is the more noteworthy, because there does not seem to be either here or elsewhere in the psalms any explicit teaching of immortality or resurrection (some have found the hope in xvi., xvii., xlix.).

Such is the relatively simple faith of the most influential book of the Old Testament, which has claimed so supreme a place in the public worship and private devotion of Jew and Christian. Its magical secret lies in its simple and concrete expression of universal religious experience. Its value is altogether independent of our enquiries into its sources; indeed, it has won its place by its lowly submissiveness to reinterpretation in order to meet the ever-changing needs of the unchanging human heart.

PSALTERY, PSALTERION or SAWTRIE, an ancient stringed instrument twanged by fingers or plectrum, and mentioned many times in the English Bible, though precisely what form of instrument is implied by these various references is doubtful. In its mediaeval form it consisted of a shallow box sound chest over which strings varying in number were stretched, being fastened at one side to pegs and at the other to wrest pins. In the early rectangular form the strings, numbering 10 to 12, were of uniform length, the pitch being varied by their thickness and tension. When the triangular form succeeded the rectangular, the stringing was that of the harp, pitch being dependent on the length. The psaltery was held in an upright position against the chest of the performer, until, owing to the increasing number of strings, it grew too cumbersome, when it was placed flat on a table or on the knee. From the psaltery descended the spinet and the harpsichord.

THE PSALTERY, A MEDIAEVAL INSTRUMENT PLAYED BY FINGERS OR PLECTRUM

PSAMMETICHUS (Egypt. PSAMMETK), the name of three kings of the Saite, 26th dynasty, called by Herodotus respectively Psammetichus, Psammis and Psammenitus. The first of these is generally considered to be the founder of the dynasty; Manetho, however, carries it back through three or four predecessors who ruled at Sais as petty kings under the 25th, Ethiopian, dynasty. It is known from cuneiform texts that 20 local princelings were appointed by Esar Haddon and confirmed by Assur-bani-pal to govern Egypt. Niku (Necho), father of Psammetichus, was the chief of these kinglets, but they seem to have been quite unable to hold the Egyptians to the hated Assyrians against the more sympathetic Ethiopians. The labyrinth built by a king of the 12th dynasty is ascribed by Herodotus to the Dodecarchy, or rule of 12, which must represent this combination of rulers. If the dynasties were numbered thus before Manetho, the numeral may be the cause of Herodotus' confusion.

After his father's death Psammetichus I (664–610 B.C.) was able to defy the Assyrians and the Ethiopians, and during a long reign marked by intimate relations with the Greeks restored the prosperity of Egypt. The short reign of the second Psammetichus (594–588 B.C.) is noteworthy for the graffiti of his Greek, Phoenician and Carian mercenaries at Abu Simbel (*q.v.*). The third of the name was the unfortunate prince whose reign terminated after six months in the Persian conquest of Egypt (525 B.C.). It has been conjectured that the family of the Psammetichi was of Libyan origin; on the other hand, some would recognize Negro features in a portrait of Psammetichus I, which might connect him with the Ethiopian rulers.

PSELLUS, MICHAEL CONSTANTINE, THE YOUNGER, (1018–*c.* 1079), Byzantine writer, was born at Nicomedia, or Constantinople, of a consular and patrician family. Under Constantine Monomachus (1042–54) he became one of the most influential men in the empire. As professor of philosophy at Constantinople he revived the cult of Plato at a time when Aristotle held the field. At the height of his success as a teacher he was recalled to court, where he became state secretary and vestarch, with the honorary title of "Υπατος τῶν Φιλοσόφων (prince of philosophers). Presently he entered the monastery of Olympus (near Prusa in Bithynia), where he assumed the name of Michael. But, finding the life little to his taste, he resumed his public career. Under Isaac I (Comnenus) and Constantine X (Ducas) he exercised great influence, and was prime minister during the regency of Eudocia and the reign of his pupil Michael Parapinaces (1071–78). It is probable that he died soon after the fall of Parapinaces.

In character Psellus was servile, unscrupulous and weak. But as a literary man, he will be remembered as the forerunner of the great Renaissance Platonists. His works embraced politics, astronomy, medicine, music, theology, jurisprudence, physics, grammar and history.

Of his works, which are very numerous, many have not yet been printed. We may mention: *Chronographia* (from 976–1077); three Epitaphioi or funeral orations over the patriarchs Cerularius, Lichudes and Xiphilinus, and nearly 500 letters. The most important of his works have been published by C. Sathas, who has also edited the *Chronographia* in Methuen's series (1899), in his Μεσαιωνικὴ βιβλιοθήκη, iv, 5. On Psellus himself *see* Leo Allatius, *De Psellis et eorum scriptis* (1634); J. E. Sandys, *Hist. of Classical Scholarship*, i, 411 (1906); P. Würthlein, *Rhetorische Studien* (Paderborn, 1919).

PSEUDODIPTERAL, in architecture, a term applied to a temple in which the single row of columns set around the cella is separated from the cella wall by a space equal to the distance between two pairs of adjacent columns, so that the effect is that of a dipteral (*q.v.*) temple with the inner row of the double colonnade missing.

PSEUDONYM, a false or invented name, particularly the fictitious name under which an author produces his work in order to conceal his identity. The same end is gained by publication without any name, or anonymously. The body of works thus produced either without the author's name or under a fictitious name became known as anonymous and pseudonymous literature. Many books affording a key to the identity of the various writers have been published. Though Fredericus Geisler published a short treatise on the subject entitled *Larva detracta*, etc., in 1669, the chief early work was that of Vincent Placcius (1642–99), whose *Theatrum anonymorum et pseudonymorum* was published in 1708, edited by L. F. Vischer; supplements were published in 1711 and 1740.

Other works included *Dictionnaire des ouvrages anonymes et pseudonymes* (1806–09), by Antoine A. Barbier; *Deutsches Anonymen-Lexikon, 1501–1850* (1902–07) and *Deutsches Pseudonymen-Lexikon* (1906), by M. Holzmann and H. Bohatta.

In English, R. Thomas' *Handbook of Fictitious Names* appeared in 1868. *Dictionary of the Anonymous and Pseudonymous Literature of Great Britain*, by S. Halkett and J. Laing, was revised and published posthumously in four volumes in 1882–84. Other English works were W. Cushing, *Initials and Pseudonyms*, 2nd series (1886, 1888), and *Anonyms* (1890); and F. Marchmont, *A Concise Handbook of Literature issued under Pseudonyms or Initials* (1896).

PSEUDOPERIPTERAL, in architecture, a term applied to a building or temple in which the cella or enclosed portion has engaged or attached columns which line with the side columns of the front porch or portico, and thus simulate a surrounding colonnade.

Examples are: the temple of Zeus at Agrigentum in Sicily (late 6th to 5th century B.C.), in which all the columns of the exterior are attached to the cella wall; and the more usual *Maison Carrée* at Nîmes (constructed in 16 B.C.). In certain Roman ex-

amples, such as the temple at Tebessa in Algeria (early 3rd century after Christ), pilasters replaced the engaged columns.

PSICHARI, ERNEST (1883–1914), French author, grandson of Ernest Renan, and son of Jean Psichari, director of studies at the École des Hautes Études in Paris, was killed on the western front on Aug. 22, 1914. He was one of the leaders of the young generation before World War I who sought to "rationalize" war and the defense of their country; he sought to provide the psychological basis for heroic action.

His work is that of an intellectual who must justify the "great sacrifice." In the year before World War I *L'Appel des armes* had a powerful moral effect among young intellectuals. It is the story of a captain in the Algerian army who converts to the military ideal the antimilitarist son of an internationalist, who finds mental peace in military obedience.

This book was followed by *Les Voix qui crient dans le désert. Le Voyage du centurion* appeared as the finished form of this work. In 1917 Jean Psichari presented to the Luxembourg library his collection of 25,000 volumes on mental subjects, in memory of his son Ernest. A second son, Michel, was killed in May 1917.

Bibliography.—Henri Massis, *La Vie d'Ernest Psichari* (1916); L. Aguettant, *Ernest Psichari* (1920); A. M. Goichon, *Ernest Psichari*, etc. (1925).

PSILOMELANE, one of a group of hydrated manganese oxide minerals, with very similar appearances and properties, which are difficult to distinguish. They frequently occur in hard black botryoidal or stalactitic masses with a smooth surface, hence the name from the Gr. *psilos,* smooth, and *melanos,* black. However, they may also be soft and earthy. They are distinctly crystalline, and not amorphous as once supposed. The name "psilomelane" was originally applied to material from Schneeberg, Saxony, which has the formula $BaMnMn_8O_{16}(OH)_4$, and should be restricted to this composition. The other manganese minerals of similar appearance should be referred to as being of the "psilomelane type" until their exact nature is determined. Among these have been distinguished, on the basis of chemical analyses and X-ray photographs, the following species: Cryptomelane, with a formula approaching KMn_8O_{16}, occurring in crystals and cleavable masses as well as in botryoidal form. Cryptomelane is probably the most common of the psilomelane type of minerals. Others are hollandite, with a composition approximately $BaMn_8O_{16}$; coronadite, $MnPbMn_6O_{14}$; rancieite, $CaMn_4O_9.3H_2O$ (?); and lithiophorite, with complex composition, being hydrated and containing lithium and aluminum in addition to manganese. They are associated with other manganese ores and derived from them by weathering. (*See* also Pyrolusite.) (L. S. Rl.)

PSITTACOSIS, an infectious disease endemic among various species of birds, notably parrots and parakeets, lovebirds, doves and occasionally in other species. It is transmitted to man ordinarily as a dust-borne infection from the excreta of birds. This dust is inhaled and occasions in man a pneumonia differing in a number of respects from classical lobar pneumonia. Occasional cases have occurred where the infection has apparently been transmitted from human patients to their attendants or visitors, but this occurrence is rare.

Because of the mechanism of infection it is usual that several persons in one family become infected. The history of the first recorded outbreak, reported from Uster, Switz., in 1879 by Jacob Ritter, is typical. The family kept a number of finches and parrots in the house. On Feb. 26 six small birds were received from Hamburg, Ger. One of these birds died shortly after, and between March 13 and 18 five persons in the family became ill with evidence of pneumonia, and on March 27 and 29 two more persons became ill, one a frequent visitor to the family, the other the person who came in to care for the birds after the family got sick. Three of the seven patients died, and autopsies, revealing a lobular pneumonia, were performed by Eberth.

Clinically the disease is characterized by a hacking cough which produces little or no sputum, by a stuporous or "typhoid" state, by the gradual extension of the pneumonia through the lung, as watched by repeated X-ray examinations, by the rather long (two to three week) duration of the pneumonia and by a long convalescence. In the preantibiotic days mortality was high. Some benefit was reported from the use of penicillin, chloromycetin and aureomycin.

As noted by Eberth, the pneumonia is lobular in character, and in the fatal cases is often confluent and widespread. There is an apparent sequence of congestion and oedema, red hepatization and gray hepatization, but all phases are commonly present in the same lung and even in adjacent areas. This sequence corresponds histologically to a primary exudate of fibrin, red corpuscles, polymorphonuclear leucocytes and epithelial cells, later replaced gradually by large mononuclear phagocytes and epithelial cells. The causative organisms are sometimes found as clusters of small rounded and elongate (cocco-bacillary) rickettsialike inclusion bodies in swollen attached and desquamated alveolar lining cells.

In earlier outbreaks various bacteria had been incriminated as the cause of the disease. In the world-wide epidemic of the winter of 1929-30 the causative organism was almost simultaneously identified as a filterable virus by groups of bacteriologists in Berlin, London, New York city and Washington, D.C., and the observation of the virus bodies as small cocco-bacillary organisms, visible under high magnifications with the microscope, was also simultaneously reported from Berlin (April 5), Washington (April 11) and London (April 12, 1930).

The acute disease in birds was characterized by lesions and accumulations of the organisms in the liver, kidney and intestinal epithelium, which account for the infectivity of the faeces.

(R. D. Le.)

PSKOV, in German, *Pleskau,* a town of U.S.S.R. in the Pskov district of the Leningrad area, in 57° 48′ N., 28° 22′ E., situated on both banks of the Velikaya river, 9 mi. S.E. from Lake Pskov. Pop. (1939) 59,898. The chief part of the town, with its kremlin on a hill, occupies the right bank of the river, to which the ruins of its old walls (built in 1266) descend. The old cathedral in the kremlin has been four times rebuilt since the 12th century; the present edifice (1691–99) contains some very old shrines, as also the graves of the bishops of Pskov and of several Pskov princes. The church of Dmitriy Solunskiy dates originally from the 12th century; there are others of the 14th and 15th.

History.—Pskov, formerly the sister republic of Novgorod and one of the oldest cities of Russia, maintained its independence and its free institutions until the 16th century, being thus the last to be brought under the rule of Moscow. It already existed in the time of Rurik (9th century); and Nestor states that in the year 903 Olga, wife of Igor, prince of Novgorod, was brought from Pleskov (*i.e.,* Pskov). The Velikaya valley and river were from a remote antiquity a channel for the trade of the south of Europe with the Baltic coast. Pskov being an important strategic point, its possession was obstinately disputed between the Russians and the Germans and Lithuanians throughout the 11th and 12th centuries. It became in the 12th century a *prigorod* of the Novgorod republic; *i.e.,* a city having its own free institutions, but included in certain respects within the jurisdiction of the metropolis, and compelled in time of war to march against the common enemy. Pskov had, however, its own prince (*defensor municipii*); and in the second half of the 13th century Prince (Timotheus) Dovmont fortified it so strongly that the town asserted its independence of Novgorod, with which, in 1348, it concluded a treaty wherein the two republics were recognized as equals. Its rule extended over the districts of Pskov, Ostrov, Opochka and Gdov (farther north on the east side of Lake Peipus). The *vyeche* or council of Pskov was sovereign, the councils of the subordinate towns being supreme in their own municipal affairs. The council was supreme in all affairs of general interest, as well as a supreme court of justice, and the princes were elected by it; these last had to defend the city and levied the taxes, which were assessed by 12 citizens. But while Novgorod constantly showed a tendency to become an oligarchy of the wealthier merchants, Pskov figured as a republic in which the influence of the poorer classes prevailed. Its trading associations, supported by those of the working classes, checked the influence of the wealthier merchants.

Its strong walls and its 40 large and wealthy churches bear testimony to the wealth of the inhabitants, who then numbered about 60,000. As early as the 13th century Pskov was an important station for the trade between Novgorod and Riga. A century later it became a member of the Hanseatic league. Its merchants and trading associations had factories at Narva, Reval and Riga, and exported flax, corn, tallow, skins, tar, pitch, honey and timber for shipbuilding. Silks, woollen stuffs and all kinds of manufactured wares were brought back in exchange. In 1399 the prince of Moscow claimed the privilege of confirming the elected prince of Pskov in his rights; and though, 50 years later, Pskov and Novgorod concluded defensive treaties against Moscow, the poorer classes continued to seek at Moscow protection against the rich.

After the fall of Novgorod (1475) Pskov was taken (1510) by Basil Ivanovich, prince of Moscow, and a *voyvode* or deputy was nominated to govern the city. Moscow, at the end of the 17th century, abolished the last vestiges of self-government at Pskov, which thenceforward fell into rapid decay. Near this city the Teutonic knights inflicted a severe defeat upon the Russians in 1502. Pskov became a stronghold of Russia against Poland, and was besieged (1581) for seven months by Stephen Báthory during the Livonian War, and in 1615 by Gustavus Adolphus of Sweden. Under Peter the Great it became a fortified camp. Under the tsarist regime the province of Pskov extended from Lake Peipus to the sources of the western Dwina, and after the 1917 revolution the province of Pskov, though much diminished, remained an administrative unit. In 1927 it was incorporated in the newly created Leningrad area (*q.v.*).

PSORIASIS.—Psoriasis is a moderately common disease of the skin, of great chronicity. It may begin at any age, and a familial history of psoriasis is common. Individuals affected by the disease are ordinarily otherwise healthy; the only exception to this is arthritis in some patients. The lesions of psoriasis are usually characteristic, consisting of sharply outlined dull red patches of varying size, with thickening of the skin, and a heavy rough scale which is silvery or asbestoslike in colour.

Psoriasis has a characteristic distribution over the body in a majority of cases, involving principally the scalp, the elbows, the front of the knees and the trunk. It does not cause loss of hair. Involvement of the nails is quite common, and this may be mistaken for a ringworm infection. The disease varies a great deal in severity and in many patients it will show periodic flareups. In general, nervous tension will make psoriasis worse. There is no regular relation of the disease to any type of diet. Sunlight is usually very helpful, and a considerable variety of local treatments are effective temporarily. Most of the proprietary medicines sold for the treatment of psoriasis contain organic compounds of mercury or various types of tars. Arsenic internally was formerly used in the treatment of psoriasis, but is now rarely employed. X-ray therapy is used with decreasing frequency; it carries definite risks if used in excess. No infectious agent has ever been isolated regularly from lesions of psoriasis, and there is no evidence that the disease is in the least contagious. Compounds such as cortisone or ACTH have been employed successfully in some patients, but are variable in their effects and are justified only in the most severe cases, particularly those with associated arthritis. (D. M. P.)

PSOROSPERMIASIS, a term formerly applied to infection with any one of several groups of Protozoa, including the Cnidosporidia, Myxosporidia, Gregarinida, Coccidia or Sarcosporidia, all of which have in common a resistant spore or cystic stage, which develops in the intestines, liver, kidneys, ureters, musculature or other tissues of the host. (E. C. F.)

PSYCHE, in Greek mythology, the personification of the human soul. The importance, in Platonic philosophy, of love (in the highest sense) as an agent of the soul's progress leads, in art from the 4th century B.C., to representations, allegorical or playful, of Psyche (generally represented as a winged girl, a relic of the old conception of the soul as a bird or insect) in company with Eros (*q.v.*), usually in amatory scenes. The tale of Cupid and Psyche, in the *Metamorphoses* of Apuleius, is interesting as the only ancient fairy tale which is told as such. In it Psyche, the youngest daughter of a king, arouses the jealousy of Venus, who orders Cupid to inspire her with love for the most despicable of men.

Cupid, however, falls in love with her and carries her off to a secluded spot, where he visits her by night, unseen and unrecognized by her. Persuaded by her sisters that her companion is a hideous monster, and forgetful of his warning, she lights a lamp to look upon him while he is asleep; in her ecstasy at his beauty she lets fall a drop of burning oil upon the face of Cupid, who awakes and disappears. Wandering over the earth in search of him, Psyche falls into the hands of Venus, who forces her to undertake the most difficult tasks. The last and most dangerous of these is to fetch from the world below the box containing the ointment of beauty. She secures the box, but on her way back opens it and is stupefied by the vapour. She is only restored to her senses by Cupid, at whose entreaty Jupiter makes her immortal and bestows her in marriage upon her lover.

See O. Waser in W. Roscher, *Lexikon,* iii, 2327 *et seq.* (1924); L. C. Purser, *The Story of Cupid and Psyche* (1910).

PSYCHIATRY is that part of medicine which is concerned with the mental aspects of health and sickness and with the mental and material forces which promote or hinder the healthy functioning of the human being in personal and social ways. Psychiatry differs from other divisions of medicine because of its primary preoccupation with the personality functions. Historically, this differentiation has been heightened by specialization in medicine. The patient, as a person, has by these specialistic trends been lost to view, or dealt with at a rather superficial level, and this fact has contributed to the need for a specialty to deal with the "patient as a person" or the "organism as a whole"—terms by which modern psychiatrists have sought to indicate the subject matter of their branch of medicine.

HISTORY AND GENERAL DISCUSSION

The specialistic differentiation of psychiatry has been influenced and somewhat confused by the historical fact that psychiatry has been slower than other divisions of medicine in the development of effective rational therapy. In the 19th century "psychiatrist" was synonymous with "alienist"—a specialist skilled in the detection and management of insanity, whose main treatment was institutional segregation, with humane custodial care. During the first half of the 20th century, psychiatry grew from a descriptive to a dynamic orientation, with increased therapeutic powers and aspirations. That large division of human illnesses known generically as the neuroses or psychoneuroses has, in many communities, become part of the specialistic field of psychiatry, although in some communities these illnesses still are considered to remain in the specialty of neurology. During the second quarter of the 20th century, child guidance was added to the domain of psychiatry. Emotional reactions and personal maladjustments came to be recognized more systematically than previously as factors in many sorts of disease. This orientation to medical problems, enlarged to include psychodynamic considerations, was designated "psychosomatic medicine." Increased attention to social and environmental factors in medical practice also concentrated attention upon the emotional reactions and attitudes which determine in what way social and material circumstances may influence persons in psychological, physiological and pathological ways. These and other considerations have heightened the desire, in medical education and practice, for a substantial knowledge of human nature, which would be scientifically sound and clinically useful. The development of a fairly teachable and verifiable body of psychodynamic knowledge enabled psychiatry to make considerable headway in meeting this need. Psychiatry was therefore outgrowing the bounds of a specialty of medical practice at mid-20th century and was in the process of becoming, in part, a basic medical science.

In its role of a basic science, psychiatry is intimately related to biology and physiology, since it deals with the integrative functions of the organism. Psychiatry, however, is distinguished from classical physiology and biology because it deals so largely with

interpersonal reactions and attitudes and therefore employs distinctive techniques of interviewing and of biographical study. Theoretically, psychiatry as a basic medical science should be closely associated with the sciences of psychology, sociology and social anthropology, but historically these associations have been rather by accident than by design.

During the 19th century the human brain was intensively studied in the confident expectation that increasing precision in the localization of its functions and increasing knowledge of physicochemical mechanisms would provide a material basis for the explanation of abnormalities of mentation and behaviour. As late as 1910, Sir John Tuke, John Macpherson and L. C. Bruce stated that insanity was "a generic term applied to certain morbid mental conditions produced by defect or disease of the brain," but this should be recorded as a hopeful expectation of that generation of workers rather than as a scientifically established fact. Such brain-anatomical studies of the speech function, for example, met with a fair degree of success in the cerebral localization of lesions causing specific aphasic disorders, but even in this limited segment of personality functions complete explanation by local lesions had not been established at mid-century.

A brilliant succession of German psychiatrists, culminating in Emil Kraepelin, delineated a limited number of presumed specific diseases, such as dementia praecox, manic-depressive psychosis and paraphrenia, for which specific material causes were sought unsuccessfully. When the spirochaete of syphilis was discovered, it was demonstrated to be the cause of meningoencephalitic lesions in a certain proportion of the insane, amounting to about one-tenth or one-twentieth of the admissions to mental hospitals. These cases had previously been classified clinically as general paresis, by reason of the characteristic occurrence of muscular weakness or paralysis caused by lesions in the nervous system. A moderately successful method of treatment of these conditions by malarial inoculations was devised by Julius Wagner von Jauregg of Vienna.

Other types of diffuse lesions of the brain, such as occur in Alzheimer's disease, lead encephalopathy and encephalitis, also provide organic causes of psychotic mental disorder, most common of all being the cerebral lesions of arteriosclerosis and senile degenerative conditions. There is but a meagre correlation between the extent of cerebral damage and the severity of psychotic mental disorder; to a considerable extent, the character and severity of the maladaptive personality functioning associated with organic brain disease is determined by the previous personality. Personality functions are disturbed by toxic conditions, deficiency states and metabolic and endocrine disorders which affect the brain. And yet it remains true, in the majority of psychotic patients and in nearly all neurotic patients, that no physical or chemical explanation can be found in the brain.

Even in some of the psychotic and neurotic conditions in which no lesions of the brain have been found, a measure of therapeutic success has been gained by chemical, physical and surgical measures aimed at the disruption of neural pathways in the brain, temporarily or permanently. In one method a convulsive reaction is elicited by passing a measured alternating electric current briefly through the brain by means of electrodes placed on the scalp. This electroconvulsive therapy has been found particularly effective in interrupting depressive moods. The induction of hypoglycaemic coma by injections of insulin has had a considerable vogue in the treatment of early schizophrenic illnesses. In prolonged agitated states, unresponsive to other treatment, relief is sometimes obtained by the surgical destruction of certain tracts in the frontal lobes of the brain. The rationale for the use of these methods of acting upon the brain had not been clearly worked out at mid-20th century, but, in general, they offered means, crude but sometimes helpful, for modifying the physiological functioning of the brain, and may be integrated into the psychiatrist's strategic plans for promoting better personality functioning.

Adolf Meyer elaborated a clinical approach to mental disorders through the concept of psychobiological reaction patterns, determined by a multiplicity of developmental and environmental factors, as a more realistic and adequate formulation of the clinical facts than the limited assumption of cerebral disease processes. This broadly conceived psychobiological orientation encouraged the integration in the United States of psychological, social and biological lines of investigation in psychiatry.

Introduction of Psychoanalysis.—The potentialities for the psychological understanding of mental disorders were greatly advanced by Sigmund Freud's psychoanalytical investigations of "unconscious" mental processes through hypnosis, free association and dream analysis. (*See* PSYCHOANALYSIS.) In the psychoneuroses, and particularly in hysteria, it was possible by these methods to broaden very greatly the range of memories pertinent to a particular morbid pattern of reaction, to mobilize the emotional or instinctual forces in conflict, and to aid the patient thereby in a more adequate integration of his emotional attitudes, with permanent relief from neurotic symptoms. The therapeutic effectiveness of this method was earlier attributed chiefly to the patient's gain in insight, but further experience served to emphasize the therapeutic importance of the emotional relationship between patient and physician. The term "transference" has been used to designate a special aspect of the patient-physician relationship—the tendency for the patient to repeat toward the physician patterns of emotional attitudes previously held toward father, mother or other persons upon whom he has been emotionally dependent. This repetition is not exact. Indeed, it is precisely by reason of the potential differences that the transference situation may be so handled as to serve as a corrective emotional experience, liberating the patient from the inner tyranny of a maladaptive pattern.

Conceptions fundamental to a psychodynamic understanding of human nature were developed by Freud, who disclosed by his studies the mechanisms of repression, displacement and identification and the related phenomena of projection, conversion and rationalization. His fundamental dynamic concept was that of conflict between opposing forces deep within the personality: on the one hand, instinctual urges or propensities toward the fulfilment of basic biological needs, such as propagation of the species, collectively designated as the "id" tendencies, whose performance promises pleasure and whose frustration means distress; and, on the other hand, the experience of objective hindrances and pressures toward conformity, involving the intelligent postponement or modification of action, and adherence to an ideal of behaviour. The conscious person tends to preserve self-esteem by repression—an active ignoring or distortion of unacceptable experiences or impulses, whereby they become unconscious, but still exert influence upon attitudes and behaviour. Much repression is involved in normal, everyday living, and need not be productive of significant disorder, but in those who lack self-assurance or are poorly integrated there may develop neurotic or psychotic symptoms, or a stilted reaction formation which sets a rather rigid pattern of personality development, not obviously abnormal but unhealthy or unprofitable because so many of the potential forces of the personality are bound up in the maintenance of self-defense.

Certain philosophical and speculative ideas of Freud have also been so often implicated in discussions of psychiatry as to require some comment here. Foremost among them are the libido theory and the postulate of psychic determinism. The universal validity of these assumptions has been considered at times by some as axiomatic for a psychodynamic orientation in psychiatry, but this absolutist attitude does not now generally prevail. With regard to psychic determinism, a strong statement was needed, historically, to challenge effectively the previously prevailing materialistic tendency to limit all causal efficacy to physical forces, as if psychological experience might reflect neural events but could have no effective part in determining subsequent behaviour. It was still being sometimes argued at mid-century, that complete determinism is a necessary postulate for scientific study, in psychiatry and psychology, as elsewhere; but certainly one mode of scientific study is by experimentation, as distinguished from observation, and this distinction would be erased by the assumption of complete determinism. By recognizing a fairly large though incomplete measure of psychic determinism, appropriate respect for the forces of human nature and their modes of operation was gained. Whoever would seek systematically to modify human re-

actions and attitudes, for therapeutic or other reasons, must reckon with whatever degree of faith in psychic determinism or indeterminism is justified by available knowledge and skills; but, as an absolute dogma, determinism may be viewed as one of Freud's philosophical speculations rather than as a foundation of psychodynamic science.

The Libido Theory.—This may be rather loosely but concisely expressed as the assumption that the sexual instinct is the source of biological energy driving human nature. This theory has been, perhaps, the most hotly contested proposition in modern psychiatry. The protagonists of the libido theory developed special dialectic skill in pointing up the personal sources of emotional resistance to their doctrine, and it was not difficult to show that much of the opposition to the libido theory arose from repugnance rather than logic. A great abundance of clinical observations served to illustrate that sexual impulses, and emotional conflicts incident thereto, can be found associated with all regions of the body, and with practically any of the objects and activities intimately concerned in human living. But cumulative clinical studies by psychoanalytic methods led Freud himself to a radical modification of his original view of the role of the sexual instinct in anxiety states. The facts required, for example, the recognition of hostile and aggressive propensities as biological forces, just as fundamental as libido. Aggressive impulses are likewise subject to repression, displacement and other unconscious mechanisms, and hence are as difficult to recognize and trace, clinically, as sexual impulses.

Because such a large proportion of psychoanalytic literature dealt with sex, a widespread impression prevailed that dynamic psychiatry is concerned only with sex. This mistaken notion may be one of the reasons why psychiatry in general is somewhat repugnant to, and therefore neglected by, some persons otherwise well informed and open minded.

Instinct in Behaviour Patterns.—The post-Darwinian emphasis upon the biological nature of man gave a special importance to instinct in the formulation of basic concepts of human nature. The emphasis upon instinct was somewhat excessive and also confusing. In the fields of general biology and psychology the concept of instincts took a somewhat different course of development from what it did in the psychoanalytic literature, with resulting misunderstanding. Biologists and psychologists in general found it convenient to study instincts as behavioural patterns whose biological utility lay in the aptness of a rather specific innate pattern of behaviour for the achievement of a definite biological goal. In this sense there is but little in human behaviour to label instinctive. Psychologists and social anthropologists contributed impressive evidence that human behaviour is patterned chiefly by social custom. In the psychoanalytic literature the primary useful implication of the term instinct was not the specific behaviour pattern, but the drive or urgency toward the biological goal. Instinct is, in this usage, an innately prompting motivational force rather than a stereotyped instrumental pattern. This difference in the use of the term "instinct" impeded mutual understanding. It became possible to avoid some confusion and controversy by the invention of an adjective form "instinctual," rather than "instinctive," to connote this special motivational implication. *Instinctive* behaviour patterns may be more or less readily identified by observation; *instinctual* motivation must be inferred by the interpretation of behaviour. The difficulties of interpreting the biological motivations involved in human behaviour are very real, and it is doubtful if there would have been much progess in the development of skilful interpretation in this field without persistent detailed study of individual patients, including the adaptive meaning of symptoms, the intensive biographic study of personal issues in relation to pathological reactions, the disclosures obtained by hypnosis and free association and other clues to the unconscious aspects of mentation. The difficulties of such interpretive study of motivation are indeed so great that it might never have proceeded far without the special stimulus of the therapeutic goal—the combination of the desire of a patient in emotional distress to work through to some peace of mind, and the therapeutic enthusiasm of the physician. It has been for these reasons that the basic advances in a psychodynamic science of human nature have been made under medical rather than academic auspices. The emotional satisfactions and frustrations involved in therapy have, however, somewhat impeded scientific progress in this fundamental field of psychiatry by arousing considerable emotionalism and sectarian animosity in the discussion of psychodynamics. No general synthesis found universal acceptance.

It is possible, nevertheless, to present in the following paragraphs a broad sketch of what may be called a general psychiatric view of elementary psychodynamic principles, without attempting to point up or to iron out divergences from Freudian psychoanalysis or other special doctrines.

Psychodynamic Principles.—The primary psychopathological condition is anxiety. In ordinary speech one is said to be anxious when in disturbing suspense about some uncertain event. Although we speak of anxious situations, this is a figure of speech. Situations are not anxious; it is a person who is anxious, and the muscular tensions or even tremors which characterize the state of anxiety indicate that person's impulse to activity, which is being checked. Anxiety is closely related to anger and fear. The primitive root words imply constriction or choking in all three experiences. Constriction of the chest or throat is for many persons the most distressing feature of anxiety. In the experiences called anger or fear, there is some object or person or situation offering a fairly clear-cut point of focus for decisive reaction. Anxious situations are typically those which offer no feasible focus of decisive reaction, either fight or flight, or in which such reactions are inwardly prohibited or suppressed. In addition to tensions and tremulousness in the voluntary musculature, anxiety is also characterized by sweating, flushing or pallor, rapid or uneven heart rate, disturbances of gastrointestinal function and other indications of excitation in the autonomic nervous system.

Anxiety, in some measure and duration, may be considered a useful biological function, mobilizing the resources of the organism for sudden violent activity. Many anxious situations cannot, however, be resolved satisfactorily by any outburst of activity. Indeed one's appreciation of the situation is often somewhat befuddled, and the urge to activity may result in restless agitation or some rather aimless action which nevertheless affords a certain relief from intolerable tension. Clinically speaking, anxiety *per se* is seldom presented as the chief complaint by those driven by it to seek medical relief. The most common presenting complaints are specific effects of tension such as headache, backache, tremor or insomnia, or the physiological disturbances such as indigestion, excessive perspiration or palpitation of the heart; and the complaint is frequently misinterpreted by the patient as a sign of organic disease. Commonly, too, the patient has only an obscure understanding of the background of dissatisfaction from which have arisen the impulses involved in the anxiety reaction, especially if those impulses are incompatible with the way of life to which he or she is officially dedicated by custom and choice.

In the simpler cases, the psychotherapeutic aspect of the psychiatrist's treatment of anxiety states consists in helping the patient resolve this obscurity by a more complete and adequate review of the total situation, including facts and impulses which may have been obscured by mental mechanisms of repression or displacement. Granted that the patient is fairly free of pathological personality trends, and enjoys therefore a considerable freedom of spontaneity and self-confidence, such a clarification of issues may put him in a fair position to work out a practical solution of his situation or an acceptable compromise with what may be unalterable.

It happens not infrequently, however, that such a patient has not the full employment of mature attitudes adaptable to the real life situation, by reason of immature development or some hindering personality trend. The maladaptive personality patterns which thus prevent the therapeutic resolution of anxiety may, by the same token, predispose the patient to repetitive anxiety attacks. Some of the maladaptive patterns are particularly difficult to overcome permanently, because they offer a sort of solace and a mitigation of the anxiety state, by relieving the patient's sense of responsibility. Such, for example, are the obsessive-compulsive

pattern, the hysterical conversion reaction and the paranoid pattern.

Understanding of the genesis of maladaptive personality patterns or morbid personality trends depends upon an appreciation of the social nature of human living. Exactly the same statement can be made regarding excellent patterns and trends, but at mid-century these had not yet received the same intensive study because their fortunate possessors do not have particular incentives to submit themselves to exhaustive study. The better patterns are nevertheless of great interest and importance to the psychiatrist, for it is by their development and exercise that his patients make the most satisfactory recoveries and adjustments in life.

The most significant features of a person's environment are other human beings, for in human societies it is through interpersonal co-operation that people satisfy even the most elementary biological needs, such as food, shelter and propagation of the species; yet other persons can also be most frustrating and disturbing. Interpersonal co-operation is mediated through interpersonal sentiments or attitudes, which are as definitely the instrumentalities of human living as are the tools and skills of a person's occupation. A person's organized system of interpersonal attitudes may be said to constitute his personality—the aspect which he presents to others and the means by which he establishes and maintains relationships with others. Into the formation of these sentiments or attitudes go whatever instinctual propensities characterize man as an animal, with individual innate variations in force, direction and sensitivity, together with the effects of individual interpersonal experiences by which these propensities have been shaped into patterns conforming more or less to the generally established pattern of his culture, as modified in its impact upon the individual person by the special characteristics of parents, siblings and other agencies of acculturization. The formative years of life do present a succession of impersonal problems, in play and in work, through which capacities are stimulated and perfected, but, more significantly, these educative play problems and work problems are embedded in social settings, and the child's personality is shaped by the development of acceptable modes of adaptation in this social milieu. Satisfaction and gratification are as much social rewards as they are products of objectively successful individual effort, since they depend upon one's gaining success through behaviour, which, while spontaneous, is also in a pattern which gains and maintains the respect and affection of others. One's personality development, and particularly one's sense of security and personal worth, are strongly influenced, therefore, by the character and consistency of the social milieu of one's formative years. Some cultures, and some homes, operate automatically to arouse and cultivate individualistic aggressiveness; others through communal ceremonials cultivate even-tempered moderation and well-poised social participation. No culture provides completely uniform homes, no home brings exactly the same attitudes to bear on each of the children, and nature provides a considerable diversity of innate propensities; hence any culture affords a variety of personality patterns.

Concerning some of the pathological variants it may be said that antisocial personalities are commonly products of "bad" homes—broken homes or those permeated with hostility; obsessive-compulsive personalities are commonly products of "good" homes—good in the sense of stability and conformity but in which affection is weak and acceptance is conditional upon correct performance; hypochondriacal patterns are commonly modelled upon an example of invalidism in the home, or are cultivated by the overprotective solicitude of parents. Yet all such statements are but crude approximations, exceptions are numerous, and one of the main principles of modern psychiatric study and treatment is to conduct an individualized study of each case adequate to reveal the main recurrent theme or issue of dissatisfaction and conflict, to assess the individual's unused potentialities for dealing with this issue and to evoke a well-founded and self-assured mode of resolving the issue more satisfactorily. This thematic method of psychiatric study is what distinguishes psychodynamic psychiatry from the preceding stage which was essentially descriptive.

(J. C. Wn.)

SYMPTOMATOLOGY: SOMATIC SYMPTOMS

A wide variety of bodily changes, many of them productive of troublesome symptoms, has been found to occur in response to life situations. These somatic disturbances are often accompanied by special emotions or feeling states, but they may occur in the absence of awareness of emotional conflict. The individual, finding himself in an adverse situation, may repress his feelings and be unconscious of emotional stress. Bodily changes which occur in the absence of emotional display have often been found to be more extensive than otherwise.

Many of the bodily changes which occur in response to situational stimuli are not symptoms in the sense that they are disturbing. For example, the accelerated flow of saliva which accompanies pleasurable thoughts of eating is painless, purposeful and, as a reaction to a situational stimulus, would not be looked upon as a symptom. Blushing and weeping are other commonly observed but less agreeable bodily changes which occur because an individual finds himself in a special situation. Blushing and weeping would also not ordinarily be construed as symptoms. Other equally familiar somatic changes might, however, because they are accompanied by disagreeable sensory experiences. The wave of nausea which often accompanies fear, rapid heart action, trembling, sweating of the hands or urinary frequency are examples of such symptoms. Despite the common occurrence of these phenomena which quite obviously represent bodily changes occurring in response to situational stimuli, there has been a general lack of awareness of their implications, and of the possible relation between situation and disease. It is, therefore, of special interest that recent evidence indicates that serious disturbances in bodily functioning occur in response to life situations, which may lead to incapacity or even death.

Almost any of the bodily organs or organ systems may participate in disturbances which occur in response to threats to the integrity of the organism. All these patterns of reaction are not clearly understood, but certain of them appear to have some significance as defensive mechanisms. Tears, for example, appear to serve no function when they are shed in reaction to a bereavement or humiliation. When the same mechanism is invoked, however, as a defense against local assault by noxious fumes or dust, tears are clearly recognized as a useful device for washing away the offending substance and protecting the eyes of the threatened individual.

Tears constitute only a part of a widespread defensive pattern of a person, invoked not only in response to local threats but also in adverse life situations productive of anxiety and conflict. The defensive pattern is one of shutting out and washing away. It is characterized by partial or intermittent closing of the eyelids, tears, swelling of the membranes of the nose with obstruction of the air passages and increased nasal secretion, sneezing, coughing and often constriction of the throat, oesophagus and bronchi which may give rise to inability to swallow and difficulty in breathing with asthmatic wheezing. When such widespread bodily changes are transitory they cause little inconvenience to the subject. When sustained, however, as is often the case when situational conflicts are unresolved, they may lead to serious disease. The nasal obstruction, for example, impairs drainage and allows microorganisms located in the nose to invade the tissues and establish infection in the nasopharynx, sinuses or elsewhere along the respiratory passages.

Other serious physiologic disturbances occurring during situational stress have been recognized in the gastrointestinal tract. Constrictions in the oesophagus just proximal to its entrance into the stomach have been demonstrated. A tightness in the chest, not unlike that which accompanies coronary artery disease, or more intense burning pain, may occur.

The behaviour of the stomach has been studied in some detail during various emotional states and life situations with regard to appearance, blood supply, motor activity and secretion. Interest in this subject was given impetus by the famous studies of William Beaumont on Alexis St. Martin, a French fur trader who acquired a permanent opening into his stomach because of an accidental gunshot wound. Among his classic observations, Beau-

mont noted that the appearance of his subject's stomach varied with his mood. Later, I. P. Pavlov measured in the stomachs of dogs changes in the secretion of gastric juice brought about by situations productive of conflict. Later Walter B. Cannon described disturbances in digestive and motor activity as well as secretion in animals during crises. Studies were also made on a man whose stomach was accessible to view and who provided an unparalleled opportunity for the study and recognition of the influences of situational stimuli on that organ of the human body. This subject's rather volatile emotional life provided special opportunities for investigation. In general, in the various studies conducted, it was found that in response to situations which gave rise to feelings of fear, disgust or dejection the stomach became pale and inactive and secreted relatively little acid. This state of the stomach was often accompanied by feelings of fullness in the upper half of the abdomen and nausea. On the other hand, it was shown that life situations which gave rise to feelings of conflict with anxiety, hostility and resentment were accompanied by opposite changes in the stomach; namely, engorgement of the mucous membrane with blood, increased motor activity and accelerated secretion of acid. In this state the stomach wall was found to be relatively fragile. Minor insults caused injury with the formation of small bleeding points and erosions. In this state, too, the pain threshold in the stomach was found to be greatly lowered. (*See* PAIN, SIGNIFICANCE OF.) Thus, when a state of sustained overactivity and engorgement prevailed in the stomach, heartburn and localized pain in the upper half of the abdomen commonly occurred. There is considerable evidence to indicate that the changes in the stomach which occur during such pernicious emotional states set in motion a chain of events which leads to peptic ulcer.

Lower in the gastrointestinal tract, changes in blood flow and motor activity in the colon have been observed to occur under circumstances of situational stress and it is thought that these disturbances form the basis for the development of colitis of various types.

Like the gastrointestinal, the cardiovascular system commonly participates in patterns of bodily reaction to situational threats. Rapid heart action and disturbances in rhythm give rise to palpitation and occasionally cardiac pain. Transitory high blood pressure with all its attendant symptomatology has also been induced experimentally during discussions of emotionally charged situations. There is some evidence to indicate that serious sustained hypertension may occur in reaction to situational stress.

Alterations in blood flow through the kidneys have also been demonstrated experimentally during variations in emotional state. If a sustained reduction in blood flow occurs, a mechanism is provided which may contribute to the development of hypertension.

Disturbances in the contractile state of peripheral blood vessels may also give rise to symptoms as in the case of cold hands and Raynaud's disease, in which circulation to the hand is reduced below the requirements of local tissue metabolism. During an attack the hands become pale, blue and painful and finally red as the attack of vascular constriction subsides.

Symptoms arising elsewhere in the body have been shown to occur in response to situational stimuli but at mid-20th century had been studied less thoroughly than those mentioned. Changes in salivary flow appear to have some importance. Subjects with unexplained halitosis were found to display a marked diminution in salivary secretion which thus impaired the normal washing effect of saliva in the mouth.

Skeletal muscle tension prevailing in any of several parts of the body frequently gives rise to troublesome symptoms. The familiar "wryneck" is an example of such a disturbance. Many troublesome pains in the back which may lead to serious incapacity have been traced to sustained contraction of spinal muscles occurring as part of a reaction to a situational threat or dilemma. It is likely that other painful conditions of the extremities have a similar origin.

Fever, elevation of the white blood cell count, skin disorders, disturbances in vision and, indeed, in almost any of the bodily functions may occur as part of a reaction to situational threats.

Most common among symptoms which are related to life situations and emotional state is headache and by far the greatest proportion of headaches occur in response to problems of situational adjustment. Two separate mechanisms have been described. One is responsible for tension headaches and the other for migraine. Tension headache is usually characterized by a dull ache, persistent and nonpulsatile, located most often in the occipital region and associated with slight local tenderness and stiffness of the neck. Tension headache is caused by sustained contraction of underlying muscles whose products of metabolism accumulate between the muscle bundles and stimulate pain nerve endings there. The tension may spread around the head producing a painful sensation of bandlike constriction. Tension headache occurs in reaction to situational conflict and most characteristically occurs in association with feelings of emotional tension.

The headache of migraine is usually more intense than tension headache. It arises as a result of overdilatation of arteries, mainly of the scalp, with resultant stretching of their walls by the pulsating column of blood which they contain. Migraine characteristically occurs among conscientious, perfectionistic people who relax poorly. They have been called "stress addicted" because of their compulsive need for striving and adherence to standards.

More strictly psychiatric disorders may be marked by any of the above symptoms and symptom patterns attributable to alteration of body physiology. If a patient has an especially low threshold for reaction to pain or if, because of some conditioning experience, the painful part has acquired special symbolic significance to the individual, he may overreact to minor physiologic disturbances and become incapacitated by disturbances which would go unnoticed by the average subject.

In addition to the serious physiologic disturbances described above as occurring in response to difficulties of situational adjustment and the overreaction to minor disturbances, it appears likely that certain somatic symptoms which accompany psychiatric disorders are entirely "imaginary," having their origin above the segmental levels in the central nervous system. The bodily delusions which accompany psychoses appear to be disturbances of this type, as do the puzzling losses of bodily function which characterize hysteria. Evidence on this point, however, is far from complete. It is largely based on the fact that the distribution of hysterical anaesthesias, for example, often does not correspond to the arrangement of the neurons within the nervous system; on the fact that reflex activity may be undisturbed in an instance of hysterical paralysis in which all voluntary power is lost; and on the fact that from a total disability sudden complete recovery may occur either spontaneously or under hypnosis.

There are few psychiatric disorders which are not accompanied by some somatic symptoms or disturbances. The body usually participates prominently in efforts of the organism to adjust to its environment. Thus, when depression settles on the individual's thinking and emotional reactions, not only are his mental processes slowed but his whole body is likely to become slowed and he may display a paucity of skeletal movements as well as depressed visceral function with, for example, diminution in salivary secretion leading to halitosis and diminution of the motor activity of the intestines leading to constipation.

Somatic symptoms are a part of psychiatric disease just as the body is a part of the organism and hence shares in its reactions to environmental forces. (*See* also NEURASTHENIA.)

PSYCHOLOGICAL DETERMINANTS: DYNAMIC PSYCHIATRY

The principles of psychological motivation revealed by the study of the mental processes of the patient, and the application of these principles in modern psychotherapy, are usually referred to as "dynamic psychiatry." This approach to the problems of neu-

rosis and psychosis is primarily concerned with the adaptations of an individual to his emotional needs, to the realistic and cultural demands of his environment and to the stresses imposed by relationships with other people.

The technical principles, discoveries and concepts of dynamic psychiatry developed phenomenally during the 20th century, and were influenced throughout by psychoanalysis (*q.v.*). But though there are many diversities of technique, as well as theory and objective, among those who specialize in dynamic psychiatry, all have in common one basic principle unique in medicine—the study of the ideas and other subjective experiences of the patient. Much of the human psychic life is for everyone a private world, consisting of daydreams, secret loves, secret hates and secret fears, and the study of these elements of mental life is the raw material, the empirical basis, of dynamic psychiatry, this modern contribution to psychopathology and to treatment.

Concepts in Dynamic Psychiatry.—*Adaptation.*—The cardinal concept of dynamic psychiatry is that all reactions of the human organism serve the basic need to secure an optimal adaptation to internal and external stresses. Such a perspective creates a revolutionary attitude to psychotic and neurotic problems. Whereas descriptive psychiatry is concerned essentially with the diagnosis and classification of abnormalities, the techniques of dynamic psychiatry repeatedly demonstrate that apparently harmful mental symptoms or modes of behaviour are in fact adaptations to forces unknown to the patient. The arbitrary differentiation of "abnormal" as contrasted with "normal" (or "sick" as contrasted with "healthy") consequently dwindles in significance, and the therapeutic problem becomes the question of why psychotic adaptations necessitate a tragic limitation of social function, and neurotic adaptations, almost by definition, involve suffering and failures.

Dynamic psychiatry assumes that the potentiality for a great variety of psychological needs and social patterns varies in each individual in accordance with his individual physiology and inherited endowment, and that development involves the activation and suppression of these potentialities by environmental influences, especially those of infancy and childhood.

The environment is a major component of those stresses to which the individual must adapt. Indeed the ability to create situations compatible with gratifying interpersonal relations is one of the major problems of life and a major criterion of mental health. Environmental problems include those of social status and class, convention, ethics and group morality, economic problems, problems of school and vocational adjustment, relationships with friends, family and other members of the community. Besides the more concrete societal institutions, there are the cultural attitudes, especially conventional standards of behaviour, religious dogmas, criteria of success and failure, all the mores and manners of a society which offer many variable possibilities of social adjustment in a complex civilization. What is acceptable in one culture or its subdivisions is unacceptable in another, and what is socially significant and impelling for one individual is unimportant to another.

Psychiatric methods which emphasize predominantly the social aspect of adaptation are occupied chiefly with the conscious and rational elements of human behaviour. For social stresses are reflected and consciously recognized in the more superficial types of introspection, in the self-conscious awareness of inferiority feeling and in phantasies that fundamental personality problems can be relieved by a new vocation or habitation, or even by the ever-prescribed rest cure, whose results are notoriously ephemeral. The limitations of social psychiatry in therapy are a result of the fact that repeated failures in social adjustment are usually the consequence of the basic internal conflict rather than its cause. This is especially true of adults, whose social relationships and problems are determined to a great extent by the healthy and neurotic components of the personality itself. The younger the individual, the more true is the statement that he is reacting to excessive environmental difficulties rather than involuntarily creating them. Consequently the psychiatric importance of the immediate environment as a primary factor is greater in children than it is in adults, while in infancy the stresses imposed by a milieu over which the individual has utterly no control approach 100%.

Conflict.—Adaptation is largely a process of resolving various conflicts between intrinsic and extrinsic stresses experienced by the individual. There are the social conflicts discussed above, in which the individual must adapt strong impulses of his own to those of other people or to his culture. But there are many other basic types of conflict. There are conflicts between the need to be dependent and independent, to be both dominant and submissive, and those resulting from love and hate of the same person. There are conflicts resulting from dual reactions to the same stimulus; for example, the feeling that the physical manifestations of sexuality are both desirable and disgusting. Another important group consists of the conflicts between the need for various forms of pleasure and the moral feelings. Consideration of conflicts between what one wants and fully conscious moral codes only scratches the surface; for many basic conflicts are shown by modern psychiatry to involve a guilt which is not consciously recognized. Most important of all, in the experience of modern psychiatrists, are the conflicts between adult desires and attitudes and needs of childhood which still press for gratification.

Repression; Emotion and Motivation.—A major reason why a basic conflict, or one of the components of a conflict, is unrecognized by the individual himself is the process known as "repression." This consists of the exclusion of a motivating memory or phantasy from consciousness. Study of repression by special methods shows that "maladjustments" and neurotic symptoms are themselves resultants of this adaptive process. For repression spares the individual an experience still more painful than the symptom itself, especially the emotion of anxiety and its derivatives, apprehension and guilt.

Repression affects more than ideas; it also often excludes from conscious experience the emotion associated with ideas which can produce a conflict. This was a basic discovery, for emotion is regarded by dynamic psychiatry as the primary factor in motivating psychological and social adaptations. It is emotion which impels us to act, or to want to act, in certain ways; ideas have no effect without feelings. Emotions are the representations of physiologic processes in the autonomic nervous system; they are the subjective components of biologic needs which impel the human organism to strive for various pleasure-yielding goals. Primitive emotions are, however, modified by environmental influences, especially those of infancy, which predispose the individual to conflicts. The empirical task of the dynamic psychiatrist therefore resolves itself into studying those groups of ideas (complexes), and especially the phantasies, through which alone he may identify the true meaning of the individual's emotional demands, his drives and the conflicts which have undergone repression.

Fixation and Regression.—Techniques for investigating phantasy material show that many repressions are significant because they involve not only the emotions activated by immediate experience but also situations originating in the past, often the remote past of infancy and childhood. This is explained by the fact that some emotional situations were not originally resolved by satisfying behaviour, but by repression. Such complexes are said to represent "fixations" to immature types of imagery and emotional need. In other cases the crucial conflict is in the present, but is avoided by unconscious replacement of the current conflict by a more immature pattern, a mechanism termed "regression." Both fixation and regression show why much of the motivation of maladjustments is inexplicable to the rational mind; conscious introspection in terms of logic and the realities of the present cannot account for phenomena motivated in these ways. Thus, "rationalization," or the effort at logical explanation of emotionally motivated reactions, becomes a fruitless mental labour and fails to achieve its purpose of solving an emotional problem.

Character Patterns.—The effects of the conflicts, fixations and repressions of some patients are more apparent in patterns of conduct productive of suffering and frustration than in the symptoms and inhibitions which result from simple repression. Each neurotic behaviour pattern is characterized by compulsiveness so that an endless amount of reasoning with oneself will not and cannot cure

the inevitability of reacting in certain ways unacceptable to other individuals and groups. Many other character patterns are not neurotic, but the less rigid characteristics of an individual's own way of adapting himself to others; these unneurotic traits are less compulsive and more modifiable than neurotic patterns, but they too are products of developmental influences and comprise the total means at the disposal of the individual for adapting successfully and with flexibility to variable situations.

The Integrated Personality.—Emotion, drive, conflict and their consequences are not, however, the only elements affecting adaptation. A basic need to function effectively determines how well the individual can organize co-ordinated responses to all stresses, and the more effectively integrated the personality, the more subordinated crucial conflicts are to conscious intention and reason and to the demands of the present and the expectations of the future. Mature integration results from a long process of growth, in which the innate development of physiologic processes, learning and the successful nonrepressive solution of emotional demands at various levels of maturity all play conspicuous roles. Pathological failure of the integrative functions is most conspicuous in psychoses, where gross failures of integration make adaptation to adult society impossible. They may also be severely impaired in problems of character and behaviour, and are always impaired to some extent by any neurotic symptom or tendency.

Psychological Ontogeny: *Development.*—All these facts and concepts which distinguish dynamic psychiatry—adaptation, conflict, fixation and regression, immaturities of character and integration—led to special knowledge of the development of personality and interpersonal relationships, and of its role in maladjustment. Only through understanding why and how an individual's personality was formed and modified at various levels of development does one attain an adequate understanding of his psychological motivation and social patterns. All human beings are immature in certain ways, the more neurotic conspicuously so; everyone is still at times a little boy or little girl seeking to find the satisfaction denied his childhood wishes, failing to adapt to all his conflicts maturely. Dynamic study of the abnormal mind and character has therefore led to basic discoveries of the nature of the normal child and his problems, and of vital aspects of his emotional development. These results have manifold ramifications in pedagogy, social hygiene, preschool psychology, anthropology, sociology and medicine. Dynamic psychiatry learned much about psychopathology, therapy and the aetiology of some organic diseases; but above all it learned that personality is built on the emotional experience of the past. People do not "grow out of" the unsolved problems of childhood—they encounter them and reproduce them again and again in forms no longer recognized for what they are. The more painful or socially futile adaptations become the objectives of the psychiatrists who approach therapy as primarily a problem of the dynamic understanding of what deeply affects the individual's modes of solving his conflicts and meeting the world of other people. (I. Hk.)

TREATMENT

Psychotherapy.—Psychotherapy is a term used in two ways; *i.e.*, (1) as a semitechnical name for all homely common-sense aids to wise and peaceful living, and (2) as a technical term for those specific methods of treatment which take up where the simpler remedies fail, and attempt to eliminate those compulsions which force people in the face of their own better judgment to live unhappily and unwisely.

In the first sense, psychotherapy is as old as human culture, and includes every effort to shape human thought, feeling and behaviour, whether by education, precept or example, by command or exhortation, by reason and logic or emotional inspiration, by distraction and diversion, by stern discipline or by indulgence and deliberate escape, by punishments and rewards, by direct material relief or by other subtler alterations in the external environment. Finally it includes the influence on the individual of such cultural forces as religion, music, the arts and literature. Such aids have always been used by wise parents, clergymen, teachers and social workers. They are in no sense new: the Greeks in their healing temples used music and occupational therapy as adroitly as does the modern hospital. Nor are they a psychiatric discovery. They are important aids to normal development and education; and while they require patience, tact, intuitive sympathy and practical wisdom, they require little technical psychiatric knowledge, because they are not the specific tools by which neurosis as such is cured. No matter how imaginatively they are used, no matter how much sympathy, intuition, firmness and common sense are employed in their application, these aids by themselves can never resolve the ultimate source of discontent in human life; *i.e.*, the neurotic conflicts which every adult inherits in greater or lesser degree from his own infancy and childhood.

Yet these simple components of psychotherapy perform several useful functions. In the first place, they are a practical test of the severity of a neurosis. Where they succeed, their success proves that the roots of the disturbance were superficial. On the other hand, where after persistent use they fail, their failure proves that the neurosis is more deep-seated. This self-evident fact is often overlooked; and patients, their families and their physicians often blame themselves for the loss of time involved in giving a fair trial to simple measures. Such self-reproaches are justified only when such efforts persist too long in spite of repeated failure, usually out of a prejudice against turning to more precise psychiatric help.

Second, the homely psychotherapeutic methods often exercise an important palliative function, by teaching a patient how to live with some measure of comfort within the limits imposed by an uncured neurosis. In itself this often gives enough relief from mental suffering to constitute a valuable contribution both to the patient and to his family.

Third, these remedies provide an invaluable foundation for deeper treatment. A severe neurosis often causes such complete disorganization in a patient's life that he can turn neither to work nor to play for gratification and self-esteem. For such a patient, intelligent guidance may find healthy activities which in turn may make it possible for him to go through prolonged treatment without breaking down.

Fourth, concurrently with these general introductory measures, the psychotherapist must often undertake considerable emotional re-education. In essence this consists of a careful effort to increase a patient's tolerance for his own instinctual needs, for jealousies which are born in family stress and for the hostilities, fears and guilts which arise out of such conflicts. In this aspect of treatment, group methods may at times be particularly effective.

There are limits, however, to what can be achieved by such direct education, and, when it is pushed too far, patients may reject truths about themselves which are quite obvious to others, because of the fear and guilt which these truths evoke. The essential task of psychotherapy as a science is to remove from the patient's mind those barriers which make it impossible for him to recognize the obvious. Before these barriers are removed, no one *can* tell a patient much of anything; once the barriers are gone, no one *need* tell him.

This fundamental principle of psychotherapy runs counter to much of what is naïvely called common sense; and since even experienced psychiatrists frequently violate this rule, it is small wonder that physicians, nurses, laymen, clergymen, educators and parents are constantly stubbing their toes against it. They offer a patient or relative excellent arguments, reassurance, consolation or sound corrective advice, and then wonder why he agrees verbally yet fails to act on their precepts, or even reacts with panic or rage or depression, instead of with the relief, reassurance and encouragement that had been anticipated.

Yet, if wisely used, even such failures as these need not be without value. They are wasted and even dangerous only when the deduction that should be drawn is rejected, and the psychotherapist stubbornly and perhaps with angry impatience persists in his blunt technique of confrontation. If, on the other hand, he realizes that the patient's seeming recalcitrance arises from deep-rooted unconscious resistances, and if he modifies his technique accordingly, then he has taken a first step toward the eradication of those resistances and of the unconscious obligatory pat-

terns of behaviour which constitute the core of the ubiquitous neurotic component of human nature.

These references to an essential core of the neurotic process, and to a ubiquitous neurotic component in human nature, imply that an understanding of the nature of psychotherapy requires some comprehension of the nature of the neurotic process which scientific psychotherapy aims to combat. Therefore it is necessary to describe more precisely what is meant by neurotic as contrasted with normal. What are the essential differences between neurotic and normal actions, thoughts and feelings? Their differences are found not in the kind of behaviour, not in its legality or illegality, its responsibility or irresponsibility, its social or antisocial values, its rightness or wrongness, its statistical frequency or its conformity to social customs, not in whether or not it seems to make sense, but solely in the nature of the psychological forces which determine and control it. For instance, to stand on one's head in the middle of a street is normal behaviour when it is done to pay an election bet or as a hazing stunt; but the same act is neurotic if it occurs in obedience to an unconscious inner compulsion. Similarly, to wash our hands is normal, but not if it has to be done hundreds of times each day under the whiplash of a blind compulsion, which leaves the patient haunted by a fear that his hands are still dirty. Many such examples could be given, all adding up to the same conclusion; namely, that the difference between normal and neurotic lies not in the act but in the purposes served. And here the significant difference is whether the motivating forces are predominantly conscious or unconscious.

There is conclusive experimental and clinical evidence that every event in human behaviour is the product of motivating forces in which conscious and unconscious processes are mixed together in varying proportions. In such a mixture the conscious purposes are alterable by experience. They respond to reason and exhortation, to successes and failures, to rewards and punishments. As a consequence, behaviour in which conscious purposes play a major role is flexible, adapting itself readily and usefully to external realities. On the other hand, the unconscious purposes in human motivations behave as though they were deaf and blind. Life seems to exert little influence on them. They are not spurred by success, nor deterred by pain and defeat, nor altered by argument, reason or exhortation. Consequently, behaviour which is determined by a preponderance of unconscious purposes is rigid, inflexible and poorly adjusted to external reality. It is this component of human nature which limits our ability to learn either by our own experiences or by the experiences of others.

The second major characteristic of neurotic behaviour arises from the fact that the symptomatic acts and feelings to which unconscious forces give rise never succeed in discharging the psychic energies which are bound up in these unconscious purposes. As a result, in addition to being rigid and inflexible, neurotic behaviour is blindly repetitive and insatiable. This then is the essence of what is meant by the neurotic component of human nature. In widely varying degrees it is found in every human being; and it is against this aspect of human behaviour that scientific psychotherapy is directed; *i.e.,* against those intricate unconscious forces which produce that which is rigid, inflexible, insatiable and repetitive (to wit, "neurotic") in human conduct. It is evident, therefore, that these unconscious forces must inevitably be blind and deaf to the homely common-sense measures which constitute the simple art as contrasted with the intricate science of psychotherapy.

What tools have we, then, by which these obligatory unconscious purposes can be altered? In essence, the goal of all such therapeutic techniques is to reduce the influence of unconscious mechanisms in human life, partly by bringing them under conscious control, and partly by giving some form of adequate discharge to their stored-up energies. The aim is to achieve freedom not merely from superficial symptomatic disturbances, but from the underlying and unconscious sources of neurotic symptoms. Whether this is attempted by accepted psychoanalytic technique, or by such derivatives as analysis under hypnosis or under chemical sedation, the emancipation of the patient requires that in some measure he recapture and relive those past experiences in the course of which the disturbing unconscious purposes were laid down.

This is never easy. Psychiatry had to learn that human beings are very reluctant to revisit the painful and forgotten past, and that patients must be brought carefully and slowly along this path. The importance of recapturing the past was understood by the end of the 19th century, but not its difficulties. Consequently at that time it was attempted by direct suggestion or by impressively commanding the patient to remember, sometimes with the patient in full consciousness, sometimes when he was under hypnosis. This method was soon abandoned, however, because with many patients it failed, while it forced others into premature recovery of material for which they were unprepared, with the result that instead of therapeutic responses, explosive and sometimes disastrous emotional reactions occurred. Therefore, direct exhortations and commands were gradually replaced by the psychoanalytic technique, in which free associations were used to explore the deeper interconnections between psychological processes. In turn this led to a recognition of the fact that certain powerful emotional forces are set in operation in every psychotherapeutic relationship, forces which came to be known as "the transference." It was given this name because the relationship between the patient and the therapist is a mosaic in which many of the feelings which the patient experiences with respect to the physician are feelings which he originally had in earlier and intrinsically more important relationships, and which are now reactivated and re-experienced as though they were about the therapist. The psychotherapist thus becomes in reality a sample drawn at random from a human grab bag, whom the patient has unwittingly vested with special emotional importance, so that he comes to represent all the phantasies with which the patient unconsciously distorts his view of the people who inhabit his world. Therefore the study of such transferred feelings of fear and anger and indifference and affection gradually throws light on a patient's relationship to the world at large. Psychotherapy consequently includes not merely a study of free associations, but also of the fluctuations in the emotional attitudes of the patient toward the therapist. Such transference phenomena are universal; but in psychotherapy the meaning of the transference is brought to the surface and clarified, and the relationship is actively manipulated to further the therapeutic process.

By means of these two weapons (*i.e.,* the study of free associations and of the transference relationship) the patient's conscious and unconscious psychological processes are explored. The material covered ranges over the patient's entire life, from earliest infancy to current years, and includes without prejudice or preference his past and current life, his phantasies and his dreams. Any such painstaking search must of necessity proceed slowly, especially since violent emotional obstacles to the search constantly have to be overcome in the process.

Other levers with which psychotherapy exerts an influence on the underlying neurotic process can be summarized as follows:

1. The transference relationship exercises a powerful modifying influence upon the harsh, unconscious, self-condemnations and self-rejections which dominate much of that which is neurotic in human personality. This therapeutic influence is exercised largely through the passive listening attitude of the therapist, which is far more permissive and reassuring in its implications to the patient than any amount of active argument can be. Indeed active reassurance often serves merely to kindle doubts about the therapist, whereas his patient silence creates in the patient's mind doubts of the validity of his own self-condemnation.

2. In the same way, the transference forces gradually undermine the authority of the condemning parental images which are hidden deep in the unconscious psychological processes of every patient. In the therapeutic process these rigid parental images are slowly replaced by more tolerant, permissive and mature judgments. The literal taboos of childhood give way to the qualified judgments of maturity, until the patient is enabled to build up a conviction of his own right to feel, think, speak and finally act.

3. In this gradual process, the therapist's interpretations play a critical role; but the way in which the patient utilizes these

interpretations depends on the extent to which the self-condemning attitudes have been modified through the relationship that has been created. When it is successful, interpretations lead gradually to the recovery of memories, to the reliving of the past and to the discharge of residual effects which had been stored up from the past.

4. This process is what is called the acquisition of insight: insight, first, into the fact of illness; second, into the inescapable limitations of the life with which the patient is confronted; third, into unconscious conflicts and drives; and, finally, into the sources of these conflicts. At mid-century, much remained to be discovered about the psychotherapeutic effect of insight—how and why it sometimes exercises a profound therapeutic function, and why it sometimes fails; but much experimental work was being done.

Many efforts have been made to clarify and accelerate the psychotherapeutic process; *e.g.*, by systematic use of hypnagogic reveries, exploration of free associations under hypnosis, study of free associations under various types of medication and artificial induction of dissociated states, with spontaneous or artificially induced regressions to younger ages. All these experiments shed new light on psychotherapy, and provided grounds for hope that the process would in time be accelerated. The value of these methods in the treatment of war neuroses and of other acute neuroses had been demonstrated.

Chemopsychotherapy.—Chemical aids to psychotherapy have received considerable interest and attention. In theory their origins reach back to include the use of many forms of sedatives to produce deeper and more prolonged sleep at night or relaxation of emotional tension in the daytime. To this was added an investigation of the use of large doses of sedatives to produce a state of prolonged and nearly continuous sleep lasting for days or even weeks. This was first tried in certain Swiss mental hospitals, but dropped into disuse because of uncertain results, until it was tried again in the treatment of the more acute disturbances of World War II, disturbances which were complicated by states of profound exhaustion.

Chemical agents as aids to psychotherapy took on a more specific objective; namely, to make it possible for the patient to revisit deeply disturbing experiences, while in a state of consciousness so altered that it can be likened to a kind of emotional anaesthesia. When successful, this enables the patient to explore painful memories freely, sometimes with less suffering but sometimes with an alarmingly violent emotional explosion. Under certain circumstances such volcanic eruptions seem to exercise a significant therapeutic effect. This type of experience is variously called "narcoanalysis," "narcosynthesis" or "abreaction," and has played a considerable role in the treatment of the acute upsets induced by the exceptional strains of modern warfare. It must be borne in mind, however, that in appropriate patients the same goals can be achieved under simple hypnosis, or even with direct interview techniques without either hypnosis or chemical sedation. Furthermore, the same results have been achieved using a wide variety of chemical agents, so that no claims for specificity seem to have any validity. Consequently, it is uncertain just how essential is chemical sedation or the induction of any states of partial dissociation or of altered consciousness. All this was still subject to investigation at mid-20th century, and no dogmatic statements about methods were justified. It could only be said that there existed a body of clinical experiences and of experimental work in this area which gave grounds for hope that chemical aids might produce modifications of customary therapeutic techniques, which would not only shorten the duration of psychotherapy but increase its depth and efficacy.

One other way in which chemicals have been used as an aid to psychotherapy should be mentioned; namely, to produce a temporary interference in the metabolic processes in the brain. This has been done by the use of insulin to produce lowering of the blood sugar, or by certain convulsant drugs, such as metrazol, or by electrically induced convulsions. All these manipulations are followed by what is called a "twilight state" (*i.e.*, an altered state of consciousness) which can sometimes be utilized for the exploration of important and relevant historical material which is difficult of access when the patient is fully conscious, and which can be used to evoke emotional discharges which are of significant therapeutic value.

Mental and Emotional Disturbances of Childhood.—The term mental disorders when applied to children creates impressions coloured by knowledge of adult mental disturbances. It is important to break away from this orientation to gain perspective of the childhood period and understand the important differences between the nature of emotional disturbances in children and adults. While adult disorders usually reflect the turmoil of the growing-up period, the individual carries that problem more in himself. The child, being in the formative period, presents mental or personality disorders that involve basic relationships, and other individuals, particularly parents, are a part of the problem. This means that mental disorders in children are, in the main, relationship disturbances, and both diagnostic and treatment procedures must be built around this essential fact. The main exception is found in the organic disturbances such as juvenile paresis, the sequence of encephalitis, toxic and gross endocrine disorders, etc. Here we see the direct effects of structural changes influencing behaviour and, while basic relationships colour the symptom picture, they are secondary in their effects.

This section deals with the disorders of children that arise from the process of growing up. In the essential relationships, particularly in the family, the drama of growth unfolds. Parents initiate and influence this process and a child in responding to them finds how he can be an individual and learn at the same time how he can be a part of a group. Understanding this normal growth process is essential to understanding and treatment of the mental disturbances that emerge in children attempting to solve the dilemmas universally inherent in growing up.

Normal Growth Process.—This life drama always unfolds in the setting of relationships created by adults and usually within the structure of a family. Here a man and woman create from their own life experiences the roles of father and mother guiding the growth steps of a child they have created. Out of their separate individualities a new individual gets started on a life journey. The father and mother give this new individual his biological equipment, but they also provide him with the social setting in which he discovers how to use his biological potentialities. Through his own experiences the child awakens to the universal reality that he is a separate individual in a family that defines in varying ways the kind of individual he can be.

The Dilemma of Growth.—The parents soon discover that the child is not a mechanism that automatically responds to their desires—they become aware of the individuality of the child created by their own will and from their own biological equipment. He begins to assert his own ideas and express his own feelings. Sometimes these responses are in harmony with what is required, sometimes they are in conflict. Early in the life of the child, and on through the life process, emerges a dilemma the

solution of which determines the degree of mental health in the individual. For the child this dilemma can be stated this way: How can he develop his individual self with uniqueness and with a will of his own and acquire, at the same time, a social self enabling him to feel he is like others and that he belongs to a group? How can he fit into the world that has a preconceived standard for him and at the same time gain a sense of value about himself as a different and unique individual?

The parents also have an important dilemma: How can they exercise the essential moulding influence and at the same time support and encourage the individual difference in the child? How can they encourage independence to emerge from the dependence a child must have on them?

The social forces in the culture and the biological forces in the individual operate throughout life—sometimes in harmony, frequently in conflict. Society limits individuality and the individual asserts himself against these limits. Yet it is clear that a healthy child, in becoming an individual feels both his differences from and similarity to others in his group. The culture draws its vitality from the creative contributions of its individual members. There is little enduring vitality in a society when everyone feels he must be like everyone else. On the other hand there would be chaos if every individual made being different from everyone else his primary objective.

These considerations are basic in understanding the varied emotional disturbances arising in the childhood period. There are several types of disorders which arise from the conflicts that flourish in this formative period.

Mental Disturbances Involving Aggression.—The capacity for assertive and aggressive action is normal in all protoplasm and is essential for survival. In the human being the need to bring this essential quality into harmony with social realities reaches its highest development. Many mental disturbances in children are rooted in the process of adjusting their own drives to the defining and limiting requirements society places upon them. As a sample situation illustrating a serious clash between these forces, a parent seeks help for her eight-year-old boy who "yields to no authority" and "will take nothing from anyone." These brief statements epitomize a serious deadlock between a boy who was asserting his individuality against all social controls represented by parents and school. This problem flourished in a family atmosphere charged with emotional tensions. The mother, explosive in her disciplinary efforts, had developed a highly protective relation to this boy. While admiring the assertive quality in the boy, she was frightened over the crescendo of community anger created by his flagrant definance of all authority. Out of her great fear she sought to maintain her control, and her explosive threatening accentuated the boy's struggle to assert himself against the controls he needed but could not use.

The nucleus in this problem is the common one in the over-aggressive and defiant behaviour patterns of children. The assertive capacity has a totality in early life, but under the guiding authority of a parental relationship breaks up into more partial patterns allowing for both a "yes" and a "no" response. The child, such as this boy, who maintains the negative reaction in a total way, allows no balance between yielding and assertion essential for a friendly relation to authority.

Problems Involving Withdrawal.—The boy just described was in open rebellion against all social controls. Even more serious mental disturbances develop when all this aggressive force is encapsulated and held in. Such a child withdraws into himself and allows little communication of feeling that is essential for any healthy relationship. With such reactions the child becomes silent and withdrawn, gives out very little and resists taking much from anyone. He builds from within, but in the process maintains an isolation that allows little healthy growth. A common description of him is, "I never know what he is thinking or feeling."

The first reaction describes the common pattern of the delinquent, who seeks to grow up on his own terms and against the demands of others. The second reaction describes the more neurotic and even psychotic child, who draws away from relationships and who seeks to nourish himself only from his own resources. Both reactions, however, represent efforts to solve the dilemmas of growth; *i.e.*, how individuality can be maintained in a reality that includes relationships to other individuals.

Problems Involving Overconformity.—Overconformity to social patterns, always seeking to be what others want him to be, allowing only "goodness" to be revealed in behaviour, never risking anything spontaneous—these are forms of behaviour indicating a fear of being an individual and seeking to perpetuate the infantile period by remaining an irresponsible precipitate of the parental pattern, with minimal motivation to allow the emergence of individual difference. In a sense these behaviour patterns emerge from an aggressive and controlling effort to make others carry a life force. They represent efforts to avoid the risks of being an individual and separating the child from the more cloistered setting of infancy. "I don't want to grow up" is the theme song of such a child, usually accompanied by the parental theme song of "I am afraid to let him grow up."

All growing up involves separation and differentiation. A parent presents life to a child and provides the setting in which the child can take hold of living and, in doing so, relinquish the parent and move gradually into a life that is his own. Many parents hold onto their responsibility and avoid risking the child to life. In such protected parental relations this more parasitic type of development can flourish. The child is denied the support and stimulus he needs to achieve a sense of value about being an individual in his own right. Common mental disturbances in such children are manifested by such symptoms as excessive shyness and overt anxiety, and various psychosomatic disturbances such as bed-wetting, lack of appetite, speech disorders, etc., resulting in a double distortion—normal functions of the organism are interrupted and feelings are disguised and diverted from reality. In the latter disorders, the repressed feelings accentuated by this pattern of self-development are expressed by physical symptoms.

A group of mental disturbances is rooted in certain organic deficiencies. Prominent in this group are those based on inadequate biological equipment to meet the demands of the modern world. The mental defective belongs to this group, and society has to find ways and means of helping these less adequate individuals find their place so as to utilize the potentialities they have. They need more protection, particularly during formative years.

It is important to recognize that many mental defectives make a normal adjustment to life. More make this adjustment where parents and teachers adjust their feeling and thinking to an acceptance of their limitations, thus helping them to a fuller development of what they have.

Schools have made progress in this direction by providing educational facilities designed to develop the special but limited capacities of mental defectives. This is a particularly hard adjustment for a parent, especially if the intellectual level of the family is above that of the child. Frustration and discontent can easily arise where a child of limited capacity is pushed to levels of accomplishment beyond his ability. The important fact that should be basic in social planning for this group is that normality can be achieved when we fully realize that normality for any child is the adjustment to and utilization of capacities he has.

Development of the Child Guidance Clinic.—There is little value in understanding the nature of mental disturbances in children unless this understanding is built into therapeutic procedures. With the exceptions noted, these mental disorders are rooted in the essential relationships, and the helping process must provide the opportunity for both child and parent to participate. Both are involved in the problem; both must be included in a solution involving change in both parent and child.

The modern child guidance clinic has built a structure based on the unique nature of the childhood period. It provides the opportunity for both child and parent to have growth experiences to break up the unhealthful elements in their relationship and to move together toward a healthier way of living together as individuals—one the parent, the other the child. The professional skills of psychiatrist, social case worker and psychologist are interwoven to provide this type of service. The focus is on the problem in a child for which a parent has sought help. The helping

process must include the participation of both parent and child, because the problem for which help is needed is rooted in their living together.

Child guidance clinics have had their greatest development in the United States and have made significant contributions to the understanding and treatment of childhood disturbances. These advances were possible because the clinics developed a professional method of utilizing and integrating the skills of the psychiatrist, social case worker and psychologist into a service designed to help a parent and a child. (F. H. An.)

WAR NEUROSES

Any individual, even the most normal, may develop this type of neurosis. Every man has his breaking point, since neuroses are reactions of persons predisposed to respond in an individual manner to a particular quantity of a meaningful stress. Individuals previously psychoneurotic, the psychologically immature, the withdrawn asocial person and the overcompensated tough psychopath succumb more quickly and develop more severe neuroses than do the relatively stable. Although psychiatric selection can weed out the most obvious candidates for war neuroses, objective techniques are not available for accurate and rapid selection of a mass of men; hence the only test of fitness for combat is combat itself. Psychiatric therapy administered during every phase of induction, training and into combat reduces mental stress and lessens the likelihood of psychiatric casualties.

The symptoms of war neuroses are varied, depending on the individual personality and the type and quantity of precipitating stress. Previously overt or latent neurotics react as they had in the past. The acute war neuroses are manifested by direct or indirect evidence of free anxiety. When anxiety is severe it is evidenced by a terror-stricken appearance and, often, behaviour as in a panic. Victims are tremulous, stuttering or mute, and become startled at the slightest sound. Excessive sweating, increased heart beat, dilated pupils and other signs of fear are obvious. Some men become infantile in physical regressions into simian or infantile postures and attitudes, often unco-ordinated, enuretic and drooling. In the milder states of anxiety the subject may be temporarily stuporous, restless, sleepless and without appetite. Catastrophic nightmares of battle awaken these men from their fitful sleep. Most of the anxious patients have considerable amnesia for their traumatic experiences. Many soldiers react with less obvious manifestations of anxiety but with hysterical paralyses, deficits of sensation, convulsive seizures, wobbly gait or loss of a special sense such as sight or hearing. The most frequent disturbance is manifested by functional breakdowns of the internal bodily organs and are experienced as abdominal pain, nausea and vomiting or diarrhoea, cardiac pain and irregular cardiac rhythm, or headache. A few latently psychotic soldiers develop a full-blown malignant psychosis such as schizophrenia. Others become temporarily psychotic, with pathological suspiciousness or loss of comprehension of present reality; recovery is rapid on removal to safety. Very few malignant and permanent psychoses develop, but many depressions result from a feeling of failure to carry on, from men thinking that they have not done enough or have been in some way responsible for the death of a fellow soldier through an act of commission or omission.

Among the important causative factors for these neurotic reactions are physical and emotional depletion and fatigue. Therefore, the first step in treatment is a short stay in an exhaustion centre for rest, warmth, good food and encouragement. If recovery is not effective in a few days the neurosis has become resistant or fixed, and the soldier is evacuated to a hospital where special psychiatric therapy is prescribed. This consists of techniques to uncover the intellectual or emotional amnesia and assist the patient to master his anxieties and conflicts. Return to combat is rarely successful at this level, so that reclassification for noncombatant duty is the usual outcome; if therapy is ineffective the soldier is evacuated home.

Many soldiers returned home for rotation develop signs of war neuroses for the first time. They react to a loss of the solidarity of their combat group, to feeling of guilt at leaving their units, to the letdown of their powers of defense and to a general depletion of their psychological resistance. Others returning in a depleted state are unable to master the problems of readaptation to civilianlike army life at home or to the responsibilities of their families. These delayed war neuroses are manifested by regressions into infantile behaviour patterns, by visceral disturbances, by depressive moods and by aggressive and hostile reactions to persons in authority and civilians.

Identical reactions are often delayed until problems of civilian existence are confronted after discharge from the armed services. Too many demands for adaptation on a psychologically depleted or regressed individual, and insufficient gratification, are important factors in these late breakdowns. Hence social, housing, economic and job difficulties in a period of reconversion are responsible for many war neuroses in veterans of combat.

For neurotic veterans the principles of therapy are gratification of dependent needs, uncovering and ventilation of individual psychological conflicts, stimulation to independence and a satisfactory and unfrustrated outlet for the mature drives. To this end, ambulatory scientific psychotherapy in the patient's own social setting rather than hospitalization is effective. (*See* also *Psychotherapy* above.) (R. R. G.)

SOCIOLOGICAL ASPECTS OF PSYCHIATRY

Legal and Institutional.—No specialty of medicine has so many points of tangency with the law as does psychiatry, the specialty which deals with interpersonal relations. To a large extent, although the approach is different, the subject matter of law and of psychiatry is the same thing—that is, people, and how they conduct themselves.

Nearly all legal actions involve the conduct of individuals, and where individual contact is involved there may be deviations from normal. The psychiatrist may be involved in the question of the state of mind of one who has left a will, made a contract, suffered injuries resulting in mental disorder, who is seeking the annulment of a marriage, or who is accused of having committed a crime. Many of these problems will be dealt with under other headings. There is one phase, however, which should be expanded here—namely, the laws relating to the enforced detention in mental hospitals of persons suffering from psychiatric disorders.

The mentally ill have been with us as long as history has been recorded. It is only in modern times, however, that much has been done about them by the state. The first English institution was the Bethlehem hospital (later corrupted to "Bedlam"), established by a monastic order about the middle of the 14th century; public institutions were a much later development. In the United States, no institutions for the care of the mentally ill were available before the Pennsylvania hospital, Philadelphia, Pa., took in a few patients of this sort in 1756. The first public mental institution was opened in Williamsburg, Va., in 1773. Even as late as the beginning of the 19th century, these institutions were entirely custodial and protective. They were places where the "furiously mad"—those who were menaces to the peace and welfare of the community—were confined. There was very little concept of treatment, and the institutions were called asylums—that is, places of refuge. Thanks to the activities of William and Samuel Tuke and John Conolly in England and of Dorothea Lynde Dix in the United States in the first half of the 19th century, the number of institutions grew amazingly, as did their population. In England, all mental hospitals, public and private, come under the board of control, and the laws relative to the admission of patients are enacted by parliament rather than by the local communities. Consequently, a high degree of uniformity is found in the admission and hospital practices in England. The tendency there has been to keep admissions relatively informal.

In the United States the care of the mentally ill has consistently been considered a function of the several states. As a result, there are 49 separate jurisdictions and 49 potentially differing types of commitment procedure. About 97% of the patients are in public institutions, and the private hospitals are usually under some form of state licensing or supervision.

The tendency in the United States, in the earlier days of the

country, was to keep admissions relatively simple. Usually the order of a judge was necessary to send a patient to a mental hospital and to detain him therein, but the procedure was not complicated. Indeed, many of the states permitted patients to be sent to a hospital upon the certificate of a physician at the request of the guardian or family, just as one is sent to a general hospital today. Beginning about 1870, there developed a tendency to resort to jury trials for the determination of the need of care in a mental hospital, despite the undesirable effect of this procedure on the patient. By mid-20th century, however, only one state required a jury trial for commitment; there were 11 others in which a jury trial may be held at the discretion of the judge. In 26 of the states there might be a hearing before a magistrate after an examination by two or more physicians. In four other states there is a proceeding before a board or commission, with a judge as chairman.

In at least 10 states, a patient might be sent to a mental hospital for a short period on the written request of a police officer or physician, and in 34 states, the patient who is clear enough to understand what he is doing may make application for his own admission, on a voluntary basis, being at liberty to leave when he gives the required written notice. The essentials of the procedure, then, are that there be a medical examination and opportunity for a hearing before a magistrate. The federal constitution does not guarantee jury trial for any but criminal proceedings, and the disadvantages of such trial far outweigh the imagined protection to the patient.

The order of commitment, when issued, permits the hospital to receive the patient and detain him so long as he requires care. In a number of states, the commitment as such does not deprive the patient of his civil rights. Theoretically, at least, it is solely a justification for detention. The laws relating to mental hospitals are designed to protect the rights of the patient, not only to prevent improper commitment, but to ensure humane care in the institution. Patients may have access to legal counsel and may write under seal to certain state authorities if they have complaints. The more populous states have supervisory boards or commissions which inspect the hospitals and see that the laws and regulations are enforced.

Release comes from the head of the institution, under such conditions as he may lay down when the patient's condition warrants. In the case of persons charged with crime, or convicted, the patient is returned upon recovery to custody of the legal authorities if proceedings or a sentence is still pending. The patient, if he feels aggrieved, may always have recourse to the courts by petition for a writ of habeas corpus.

There are special provisions for the commitment of the feebleminded; this group differs from the mentally ill in that they suffer only from a defect of development. Most of them are educable in the community, but a small proportion requires institutional procedures and rigid regimes. In four U.S. states at mid-century there was a provision for the commitment of sexual psychopaths, so-called—that is, those persons who are menaces to the community by reason of their uncontrollable sexual impulses, but who, at the same time, are not considered legally "insane." There were four states, also, with laws providing for the commitment of the so-called defective delinquent—that is, the feeble-minded person who has serious criminal tendencies.

Much more might be said on the question of the enforced detention of the mentally ill for care in mental hospitals. There are, however, many other legal aspects of mental disorders which should be mentioned. Many actions are brought which involve personal injury. Some of these come under the category of workmen's compensation cases, but most of them are actions in tort. In general, it may be said that if a person suffers damages at the hands of another who is mentally ill he is entitled to damages, even though the one inflicting the injury is not capable of comprehending what he is doing at the time. A far more frequent type of case is that in which it is alleged that, as a result of shock or physical injury resulting from an accident, the plaintiff has developed a mental disorder of some sort, very frequently a neurosis. Again, if there was a dereliction of duty on the part of the person who caused the injury, the injured individual is entitled to damages if he can show that he has the disability alleged.

Another type of case is that involving wills in which it is alleged that the testator at the time of making the will was not of sound mind or did not have what the law refers to as "testamentary capacity." English and U.S. law, in general, requires for testamentary capacity that one making a will shall have the ability to know the facts necessary to qualify him for that purpose, to understand that he is engaged in devising his property to others, to understand in a general way the nature and position of his property and to bear in mind those who are naturally entitled to consideration in the distribution of his estate. The law is inclined to take a narrow view of the nature of the incapacity and the symptoms shown and may be said to lean over backward in protecting the rights of the testator. For example, even though it is well recognized by psychiatrists that delusions, in general, show serious mental disorder, the law is inclined to require proof that the delusion of the testator directly affected the disposition of the property. Another psychiatric problem is that of the use of so-called undue influence; in this case, the law recognizes that the enfeeblement of old age may render a testator unduly subject to blandishments or threats in a way which, though not constituting "insanity," is recognized as abnormal.

With relation to the marriage state, it is generally held that if a person is so deranged or defective mentally that he cannot appreciate the nature of the marriage relation and its duties and obligations, his marriage may be annulled by the court upon his petition. To give relief to the sane spouse, a number of U.S. states enacted legislation entitling the spouse to receive a divorce if the patient has been suffering from mental disease and confined in a mental hospital for a stated number of years, and is certified to be probably incurable. The sociological aspects of this type of legislation are certainly open to question, as are the medical ones.

It is in criminal cases that the so-called plea of insanity achieves its greatest degree of notoriety, a notoriety which is out of all proportion to the frequency with which the defense of insanity is urged. There is a widespread impression that many criminals plead insanity in an attempt to escape the consequences of their crime, and that this "insanity" which is alleged is often of a very tenuous and unsubstantial nature. Such few cases of this sort as arise achieve publicity out of all proportion to their frequency.

Ever since about the 14th or 15th century, English law has recognized that one of the elements of crime is the so-called *mens rea,* or guilty mind, and that mental disorder may exist to such a degree as to negative this element, in which case the defendant is entitled to an acquittal by reason of insanity. The rule in force in England, and in most of the states in the U.S., was laid down in the McNaghten case in England in 1843, and has often been criticized by psychiatrists as being out of line with modern psychiatric points of view. The test, known as the "right and wrong" test, is essentially that the party accused must have been labouring under such a defect of reason from disease of the mind as not to know the nature and quality of the act he was doing, or if he did know it, that he did not know he was doing what was wrong. It is emphasized that this knowledge must extend to the very act in question and not to right and wrong in general. One of the principal defects of the so-called McNaghten rule is that it deals only with the cognitive aspects—that is, knowledge as to right and wrong, a knowledge which may superficially be retained in the face of obvious mental disorder. An attempt was made to correct this defect in a number of U.S. states, by the introduction of what is known as the "irresistible impulse" test, a recognition of the volitional or conative aspect of action, as opposed to the cognitive. This was a distinctly U.S. innovation, but of equal age with the "right and wrong" criterion. It was specifically rejected by the English and most of the U.S. courts, in spite of its being far more nearly in line with modern psychiatric views.

A person acquitted by reason of insanity must be committed to a mental hospital unless he can prove that he has since recovered, and presumably detained until it is shown that he has recovered. It has always been the rule of the common law both

in England and in the United States that no person who is unable to make a rational defense should be put on trial. If serious doubt arises as to the mental condition of the defendant before or during the trial, that doubt must be resolved before the trial is allowed to go on.

These are some of the types of situations in which psychiatry comes into close contact with the law. It will be seen that, in all of them, the psychiatrist plays a part, usually as a witness. This raises an interesting question as to opinion evidence, and the manner in which scientific information should be conveyed to juries and judges in the course of trials. A great deal of criticism has been levelled at the so-called expert witness on the grounds that he is unscientific, biased or even venal. The rules of procedure certainly tend to prevent the expert from presenting a scientific statement, and the manner in which he is presented certainly makes him a partisan, however much he may strive to be impartial. Finally, the hypothetical question as used can hardly be expected to present a fair picture of the situation under consideration. The Commissioners on Uniform State Laws drafted an expert testimony act, which was submitted to all the states, with the purpose of overcoming, if possible, the objections existing in the field of expert testimony. Massachusetts led the way, from 1921, under the Briggs law by having an automatic mental examination of defendants in certain types of criminal cases, this examination being an unbiased one. The trend was certainly, in cases of all sorts, toward a more free use of court-appointed experts who at least could come into court as impartial advisers on a scientific question. Courts recognized more and more their need of information concerning the mental state of parties to cases.

Cultural.—During the second quarter of the 20th century there was a growing recognition of the need for combining the findings and the concepts of psychiatry, especially of psychoanalysis, with those of sociology and cultural anthropology. This joint or integrated approach, called the psychocultural approach, offers a conception of the emergence of personality in a cultural setting which gives many insights into personality development and character structure and also a better understanding of social order.

The cultural emphasis, in this approach, recognizes that all over the world different groups of people have faced the same persistent life tasks—coming to terms with the environment for food, shelter and protection, maintaining order in group life and regulating human behaviour for social order. Each group has attempted the solution of these life tasks in terms of its basic assumptions and beliefs about nature and man, and has accordingly developed a symbolic cultural world which it imposes upon nature and upon man.

Everywhere people are living in these cultural worlds which they maintain by teaching the young to see, think, believe, act and feel according to their traditions. Thus people, as organisms, exist in the geographical world of nature, but they live in their symbolic cultural worlds, using the rituals and symbols, the tools and techniques, the ideas and the language and patterned conduct prescribed by tradition. Upon these traditions they have established their social order, with their institutions and formal practices, such as barter and sale, contracts, courtship, marriage and divorce, law enforcement, litigation, voting and other forms of political, economic and social activity and interpersonal relationships.

Each individual, growing up in a cultural group, will learn these prescribed patterns with greater or less fidelity to the modal way of acting, thinking and feeling, thereby developing the basic character structure of his group. Thus the members of each group will exhibit the regularities of behaviour and the persistent patterns that give rise to and maintain social order. Moreover, each individual will share much the same beliefs and ideals, and, as a member of the group, will therefore be concerned with the same "problems," personal and social, which these traditional beliefs and practices create and the social order regulates.

The psychiatric emphasis in this approach, while recognizing the coercive role of traditional patterns upon the individual, stresses the idiomatic way in which each individual receives and accepts these traditions. It sees the individual child, with his unique heredity, undergoing the process of being culturized and socialized, but learning his own peculiar version of all these required patterns of believing, thinking, speaking, acting and feeling. It especially emphasizes the emotional or affective reactions of the infant and child to the many deprivations, frustrations, coercions and punishments by which the parental demands and prohibitions are imposed. It also stresses the child's attachment to and dependence upon the parents as the dominant influence in his socialization.

The psychiatric emphasis is therefore upon the idiomatic or idiosyncratic expression of traditions by each individual who may be viewed as building up a private world of his own, according to what life experiences have meant to him and how he has felt toward his parents and other adults during the years of childhood and adolescence. The clinical orientation of psychiatry has been focused largely upon the warped, twisted, often distorted personalities which emerge from these early experiences, burdened with persistent affective reactions of anxiety, guilt and resentful hostility. These persistent feelings find more or less disguised outlets in the socially sanctioned institutions and rituals of politics, economics, professional activities and the arts, or in the antisocial actions called crime and delinquency. When these feelings are too severe to be expressed in these overt activities by an individual who has not been able to take over the cultural traditions successfully, they may give rise to mental disorders; then the individual can no longer conform to the prescribed norms of action, speech and beliefs, and so he lives wholly within his private world.

The individual personality may be viewed as emerging from these early life experiences of being inculcated with traditions, as he surrenders his physiological autonomy for social control of his functional processes—food, elimination and sex—learns to curb his impulses and his expression of emotions and accepts the culturally defined world of human relations which he translates into his own idiomatic conduct.

The psychocultural approach offers a promising way of reconciling the observed regularities and organized activities of social order with the observed variations and distortions of individual conduct, beliefs and feelings. It therefore provides a way to escape from the traditional dichotomy of society versus the individual and the older belief in complicated, often mysterious, social forces. It also rejects the survivals of ancient animism known as psychic mechanisms and similar inaccessible, subjective intrapersonal processes for the conception of an organism learning to live in a culturally patterned environment. (L. K. FR.)

Mental Hygiene.—In a narrow and precise sense the term "mental hygiene" is applicable only to that body of knowledge that bears upon the maintenance of mental health. However, the term has come to be used more loosely to cover practices that are designed to maintain mental health in which the body of knowledge correctly included in mental hygiene is applied (applied mental hygiene). Even more broadly, the term "mental hygiene" has been applied to the promotion of improved care and treatment of the mentally sick, and sometimes even to the provision of such care (psychiatry).

Mental hygiene, strictly speaking, is a part of the field of hygiene, and as such includes the facts and theory pertinent to adequate human living; that is, survival, productiveness and satisfaction. In earlier formulations, hygiene was concerned with those problems and threats to health that came from disorders or diseases of the tissues and organs of man, but by the second decade of the 20th century it began to be better recognized that health is dependent not only upon the way man's tissues and organs behave and what they experience, but upon the way man himself behaves and the way he experiences life as a person. The distinction between physical hygiene and mental hygiene is fairly

clear. The former has to do with the adequate functioning of the parts of man, such as a tissue (*e.g.*, mucous membrane), an organ (*e.g.*, the lung) or a system (*e.g.*, digestive system). The latter is concerned with man as a person (a member of a family or neighbourhood, a worker, a churchgoer, etc.).

Many scientific fields, both biological and physicochemical, contribute to the content of mental hygiene as well as of hygiene as a whole. This contribution comes not only from the more formal sources, such as laboratories, but from the everyday practice of those professions that have to do with the problems of people, such as medicine, education and social work. Mental hygiene has not been formulated into as precise principles as has physical hygiene. This is in part because of its later development, but also because the conditions under which tissues and organs live and the threats with which they are confronted are much more fixed and consistent. Their physical surroundings remain fairly constant and their climate remarkably uniform. With man himself, however, the environment within which health must be achieved is extremely variable, and even health itself is subject to different criteria as a man's milieu varies. What would be considered healthy behaviour of a person in one part of the world, living under one set of customs, becomes unhealthy in another.

Mental hygiene has to do with the enhancement of human effectiveness and the guidance of developing habits and attitudes so that they may be useful in the world in which the person must live. This does not mean a rigid moulding of a person to the average of the culture in which he lives. It means rather the development of a capacity to deviate from that norm sufficiently to take the best advantage of his talents, and, at the same time, to keep within the bounds of what society will permit, or perhaps even appreciate.

The scope and content of mental hygiene is consequently determined by those important things that influence mental health. For one thing, mental health is affected by the degree of integrity of the body. If it is diseased, or defective, the prospects of good mental health are more limited; and, vice versa, mental hygiene is concerned with the influence of unsound mental health upon bodily function and disease. Mental health depends upon the way the infant and child are prepared for and introduced to the obligations, restrictions and relationships within the family and later the community; upon the way his deviations which may not only be normal but real assets are handled; upon the respect shown for his strengths and weaknesses in educating him, and upon the mental health of his teachers; upon the way his philosophical quandaries and religious inclinations are dealt with and guided; upon the way his work life harmonizes with his ambitions, interests and talents; upon the opportunity given him through play and recreation to dispose harmlessly of destructive inclinations and to organize those that can be creative.

Mental hygiene is concerned with data that help to solve or to remove the cause of ineffective worry and anxiety. It recognizes the greater productivity and reliability of intelligence that operates free of emotional bias, yet at the same time it recognizes the role of emotional factors in effective action. Basic is its principle that behaviour is caused and so is subject to understanding and modification. This gives to mental hygiene an astounding breadth, and in fact it has sometimes been adversely criticized because of this breadth. But this breadth is inherent in the objective and is not a matter of arbitrary decision. This fact of great breadth further determines the wide extent of the professional sources from which data and experience are drawn in order to make up the body of knowledge in the mental hygiene field.

This breadth also determines the hands into which fall the responsibility for applying mental hygiene. Doctors, teachers, social workers, nurses, judges, probation officers, ministers and many others become the agents of mental hygiene. An inspection of the objectives of all these groups reveals the fact that at best they aim toward advancing the capacity of those they serve for survival, productivity and satisfaction. Insofar as one of these professions fulfills its objectives, it is serving as an agency of mental hygiene. Each of these agencies, of course, has its own special emphases, techniques and sphere of problems. At many points these interests overlap. But insofar as they employ a common body of knowledge, terminology and objectives, they tend to see themselves as part of a community of effort directed toward mental health. They see themselves, therefore, as dependent on other professions and not legitimately isolated. The content of mental hygiene affords a bridge between them.

While, broadly defined, mental hygiene includes both the treatment and prevention of disease, it is the former that has received the greater attention. This is because the handling of mental disease includes the more emergent problems, because there is better definition of the steps to be taken and more experience with the application of effort. Also the failure of government to provide adequately for humane custody and for the treatment of the mentally ill often results in intolerable treatment of patients. Physical abuse, unnecessary restraint, lack of cleanliness, poor nutrition, insufficient clothing, to say nothing of neglected medical care, are the lot of the mentally ill very generally. There is great variation in the quality of care given the mentally ill from country to country and place to place, but even the best service leaves much to be desired.

It was in fact the neglect of the mentally ill that initiated the field of mental hygiene. Many reformers arose to press for better care of the mentally ill. Among the better known toward the end of the 18th century were P. Pinel in France, W. Tuke in England and B. Rush in the United States. But all these men were speaking to a society that was not yet ready to give the mentally ill the form of humane treatment that they promulgated. There were advances and losses, but a foundation was laid to which later leaders could point. Dorothea Dix, a half century later, took up the cause and strove both in the United States and Great Britain for the provision of adequate hospitals in place of the existing forms of detention. She was eminently successful, but achievements were still in advance of society.

Clifford W. Beers, in the early 20th century, found society much readier to concern itself with the proper care of the mentally ill, and medical science had advanced to a point where better treatment was possible. Modern mental hygiene was spearheaded primarily by the initiative and energy of Beers. Beers had been a patient in a mental hospital for about three years when he conceived the idea of devoting his life to the improvement of the care of the mentally ill. An autobiography, *A Mind That Found Itself*, was the opening gun of this effort after his recovery.

In 1908 Beers founded the Connecticut Society for Mental Hygiene, the first organization in this field, and in 1909 the National Committee for Mental Hygiene (now the National Association for Mental Health) for the United States as promotional agencies. Many other states in the United States and other countries in all continents subsequently organized such associations. About 1930 the International Committee for Mental Hygiene was formed under which congresses were held in 1930 and 1937. A third congress in 1948 resulted in a reorganization into the World Federation for Mental Health, which now operates with a regular staff. The World Federation is consultant to the World Health organization, the United Nations Educational, Scientific and Cultural organization and the Economic and Social council. A fourth congress was held in 1951 in Mexico City. In addition, some professional associations in the medical, educational and other fields formed their own mental hygiene committees.

The preventive phase of mental hygiene is most frequently only relatively preventive; that is, it is designed to prevent more serious problems of mental health by dealing with simpler problems at their beginnings. Thus, child guidance clinics have been established to deal with the behaviour of deviations of children. Truly preventive mental hygiene, however, is inherent in the functions of other fields. The prevention and early treatment of syphilis is mental hygiene, for one mental disease is caused by syphilis; likewise is the development of better food habits, especially in regions where pellagra is prevalent, for some mental disease is caused by pellagra. Help by social agencies to families experiencing or threatened with disorganization is mental hygiene, for problems of neurosis and psychopathic personality frequently grow out of family disorganization. For similar reasons, careful selection and training in mental hygiene of teachers, ministers,

doctors, social workers, nurses and other professions dealing with people in need or in trouble; attunement of school curricula and other work with children to their potentialities; prenatal work with parents, especially in anticipation of the first child; and careful evaluation and allocation of workers in the industrial field are samples of activities that enhance and safeguard mental health.

The positive phase of mental hygiene focuses not on prevention of disease but on raising the level of healthy living. It begins with the fact that talents of people differ. Not only is productiveness the result of working in keeping with one's own talents, but satisfaction and happiness are to a considerable degree feelings that come from using one's talents. Positive mental hygiene is, at the same time, both preventive and curative. It is the root of occupational therapy. It reconciles what the person does with what he enjoys doing. It enhances his wholeheartedness about his activities, which is the opposite of the conflicting and mixed feelings that are often found behind mental ill health.

Special opportunities for furthering positive mental health are found in the school, where the curriculum can be adjusted to the individual needs of the child, and in industry, where employment can be similarly individualized. There are also ministers who help those whom they are counselling to work out the religious formulations and interpretations that are peculiarly valuable to the individual. Some colleges have maintained mental hygiene personnel for the guidance of students, the tendency being to relieve such personnel of administrative or disciplinary responsibility so that the student may be free to seek help on any phase of life that may be troubling him. Industry is coming slowly to appreciate the fact that employee morale and satisfaction is greatly dependent upon the quality of executive and supervisory staff. World War II likewise revealed the fact that mental breakdown in combat is directly related to the quality of officer leadership. (G. Ste.)

PSYCHICAL RESEARCH. Psychical research is the experimental study of the supernormal faculties (real or supposed) of human personality. The word "supernormal" is merely an equivalent for "not recognized by general scientific opinion" and is free of all implications of "supernatural." The function of psychical research is to collect and weigh all the available evidence for and against all such supposed faculties, to the end that they may either be accepted by general scientific opinion, or may be rejected.

Psychical research is actually a special case of general research in human psychology. The subject matter of psychical research has included such debatable phenomena as telepathy, clairvoyance, precognition, dowsing and divination, hypnosis and evidence for the hypothesis of survival after death.

The Society for Psychical Research, founded in 1882 in England, assumed an active part in carrying out experiments and in collecting evidence concerning these phenomena. Similar societies were founded in other countries, particularly the United States. No real progress was made regarding the establishment of these hypotheses after the founding of the societies, with the exception of the problem of hypnosis. Hypnosis became a recognized tool of the clinical practitioner of medicine. The collection of evidence as to the reality of telepathy, clairvoyance and precognition is unusually difficult and fraught with problems of experimental design and execution.

It is customary to divide the phenomena of psychical research into two classes, "mental" and "physical." If a table is moved without the application of any force known to science, that is a "physical phenomenon." If a medium in trance gives information outside his normal knowledge, that is a "mental" phenomenon; there is nothing necessarily supernormal in trance speaking; the supernormality is to be found, if anywhere, in the content of the words spoken. If, however, the information is given through a trumpet floating in the air at a distance from the medium, that is both a physical and a mental phenomenon. The main problem of psychical research continues to be the collection of scientifically acceptable evidence under controlled experimental conditions.

Poltergeists (a German term meaning "racketing spirits") constitute the principal type of spontaneous physical phenomena. The word is used to describe those allegedly frequent cases of strange noises, movements of furniture and breakage of crockery which are inexplicable to the inmates of the houses where they occur. Cases of this kind have been recorded for many hundreds of years and from all parts of the world, civilized and barbarous.

Poltergeist cases show a remarkable degree of uniformity in spite of their wide distribution in time and space. It can almost invariably be shown that there is some particular agent or person whose presence is essential for the production of the phenomena. Although a second agent may assist in their production, the phenomena cease at once if the principal agent is removed. The agent is usually a person of some marked mental or physical abnormality, often a girl in her "teens," less often a boy of the same age, and only rarely an adult. In some cases there is obvious trickery, easily discoverable by any fairly good observer; in others the trickery is so cleverly done that only a skilled investigator can find it out. In a few cases, trickery does not seem to be an adequate explanation of the facts, assuming these to have been accurately reported. It may be that the same motives as those for flag-pole sitting and other instances of public notoriety are involved in these strange occurrences. The problem is whether the undoubted existence of fraud (usually "hysterical fraud") in many other cases justifies the assumption that the same factor has operated in the unexplained residue. This controversy remains very much where it was left many years ago because of the paucity of adequately recorded cases in later years.

The physical phenomena have also been investigated experimentally in the séance-room. Under these conditions, limitations are placed upon the experimenter's mode of observation by the medium to such an extent that the evidence obtained from such experiments is practically useless. The investigator of séance-room phenomena soon discovers that the limits within which he is permitted to experiment are extremely narrow, that the subject matter of his proposed "experiments" (the medium) dictates most of the crucial conditions of the investigation, and that for all practical purposes he is merely a passive observer.

Two kinds of physical phenomena have received considerable study, telekinesis and teleplasm (also called ectoplasm). Telekinesis is the alleged movement of objects without the application of any physical force known to science. Its history dates back to the early days of spiritualism. Teleplasm is a "substance," extruded from the medium's body, which either may be wholly invisible, visible but amorphous, or may take the form of a complete human figure, apparently endowed with energies of its own.

For telekinesis pure and simple it should be relatively easy to formulate methods of control adequate to prevent deception without being harassing to the medium. Telekinesis would rest on a firm basis if it were certain that in all cases where positive results are reported, the conditions of control stated in the reports have, in fact, been continuously exercised throughout the sittings. But telekinesis has become very closely associated with teleplasm. The substance is reported to possess at different times such contradictory properties as to make extremely difficult the task of formulating conditions for sittings where its production is anticipated. Too delicate to endure even the lightest touch, but strong enough to shift heavy weights; sometimes so sensitive to light as not to be able to endure even the dim glow of a red lamp, at other times so insensitive as to be capable of being photographed by flashlight; how is the researcher to plan conditions in advance, when he cannot know in which form this substance may appear?

The mental phenomena of psychical research consist, for the most part, in some form of "supernormal cognition," that is, knowledge shown by a percipient of matters which he has no normal means of knowing. ("Percipient" is here used, for lack of a better word, to include not only percipients or "receivers" in telepathy, but automatists of all kinds, trance mediums, etc.). The supernormal knowledge may relate to another person's thoughts, or to events distant in time or space; it may arise spontaneously, so far as the percipient is concerned, or as the result of deliberate attempts on his part. A percipient may be in the normal waking condition, asleep, entranced, or in a state of slight dissociation produced by crystal gazing or other similar devices. Telepathy is defined as supernormal knowledge derived from another person's mind. Clairvoyance is defined as all manifesta-

tions of supernormal knowledge not so derived, for example, a capacity to see distant events and scenes without the intermediary of sensory information.

Supernormal cognition in some form is the most generally accepted phenomenon of psychical research, although there is no general agreement among psychologists as to the existence of the phenomenon. The evidence for it is impressive in quantity, but unimpressive in the quality of objective experimental control of the numerous sources of error which may invalidate the results obtained in experiments. The British Society for Psychical Research was responsible for the collection of many so-called spontaneous cases of supernormal precognition particularly of apparitions of dying or recently dead persons, seen by friends who were at a distance, and who had no normal reason for anxiety. Edmund Gurney, Frederic Myers and Frank Podmore, who analyzed the results [*Phantasms of the Living* (1886)] came to the conclusions: (1) that such apparitions occurred too frequently to be explicable by chance coincidence (elaborate statistics were given in support of this conclusion); (2) that, in the majority of cases, the most probable explanation was the transmission of an impression from the mind of a dying man to the mind of his friend, which is externalized in the form of a "subjective hallucination," rather than existing as any semimaterial wraith. The major difficulty with weighing the evidence collected from such spontaneous instances is that the experimental control desirable to eliminate fraud, collusion and other sources of error is not present because of the very character of the evidence—it is spontaneous, therefore uncontrolled and uncontrollable.

Experiments in thought transference (telepathy) have been conducted for many years in most civilized countries. The conditions of the experiments have been very diverse. Sometimes the percipients have been in a normal waking condition, sometimes in hypnosis; sometimes in the same room or house as the agent, sometimes at a distance of many miles, or even in a different country. The subject matter has also varied greatly. Attempts have been made to transfer impressions of numbers, simple or complex diagrams, the suit and value of playing cards, landscapes or pictures, incidents from books and imaginary scenes.

In experiments with numbers or a pack of cards it is possible to make a statistical computation of the degree to which the results exceed chance expectancy. In experiments with diagrams, scenes and incidents, of course, no such precise computation of theoretical probability is possible. There seems to be general agreement that experiments should be conducted using material to which standard probability statistics may be applied in order to establish a conclusion that results beyond the level of chance expectancy were produced.

Where agent and percipient are in the same room, the possibility of the use of extraneous sensory cues such as visual or auditory signals must be taken into account. Numerous experiments both in the field of psychical research and in experimental psychology have fully demonstrated that it is possible for the subject to use such cues and yet be incapable of reporting on their presence or absence.

One of the most important sources of error in experiments on telepathy and also on clairvoyance arises from the suggestibility of the experimenter in recording the results of guesses made by the percipient. The presence of this error has been established by actual inspection of records.

Even though agreement among scientific observers has not been reached regarding the hypothesis of telepathy, some individuals have considered possible ways in which the supposed telepathic impressions might operate. It has, for example, been supposed that telepathic impressions pass first from the agent's conscious to his subliminal mind, then from his subliminal mind to that of the percipient, and finally emerge from the percipient's subliminal mind to consciousness.

Psychometry is the name given to supernormal knowledge of the past history or associations of objects handled by mediums.

Precognition is the term applied to alleged instances of supernormal knowledge of future events. The outbreak of World Wars I and II and the use of the atomic bomb set a large part of the public in all countries hunting up old prophecies to see whether any of them fit. Some were found to fit quite well after they had received a little judicious interpretation. Precognition, if it is a genuine phenomenon (considerable disagreement exists as to its genuineness), does not fit very easily the previously mentioned hypothesis regarding telepathic transmission.

Most persons become convinced of survival after death even before considering the evidence furnished by psychical research; for them the question is finally settled one way or another by revealed religion or their interpretation of the facts of biology and physiology. Progress toward the establishing of a scientific basis for either belief or disbelief in survival after death remains notably lacking. The alleged evidence obtained from spiritualistic mediums and other especially "gifted" individuals did not receive general acceptance by those trained in the scientific rules of fact-finding. Psychical research has, in general, been conducted by amateurs who are unfamiliar with the necessary controls of experimental procedure involving the human organism. The history of psychical research is full of observations and experiments in which erroneous conclusions were drawn because of the absence of necessary experimental control. One need only mention the case of Clever Hans, a horse reputed to have human powers of reasoning and communication. Psychological research into the claims made for the capacities of this animal revealed that it was responding to involuntary cues provided by its trainer. When the trainer was removed from the vicinity of the animal, it no longer exhibited a remarkable capacity to add, multiply and spell.

Research in experimental psychology had not, by mid-20th century, revealed other sensory mechanisms than those described in modern textbooks of psychology and physiology. Electrophysiological research on "brain waves" had demonstrated that these electrical phenomena of the brain occur at such a low power level that firm attachment of electrodes to the scalp of the patient and several thousand-fold amplification are required in order to detect the presence of the "waves." The hypothesis that these electrical disturbances may be propagated from person to person in some unknown way had no support.

By way of summary, reference should be made to the necessary practical tests of the validity of telepathy, clairvoyance, precognition and survival of the dead. For example, the stock market represents an institution which could be very profitable to anyone gifted with telepathy, clairvoyance or precognition. Many legal cases could be more expeditiously and rightly settled if communication with the dead could be obtained. The work of law enforcement agencies could be much more precise and rapid if telepathy, clairvoyance and precognition were among the abilities of even a very few persons. It should be further mentioned that, from time to time, large sums of money have been set aside as a prize to any person who will, to the satisfaction of the members of a scientific committee, produce any supernormal human mental phenomena under the conditions of control that the scientific boards must insist upon. (*See* PARAPSYCHOLOGY.)

(W. H. SA.; J. L. KY.)

PSYCHOANALYSIS. In the years 1880–82 a Viennese physician, Josef Breuer (1842–1925), discovered a new procedure by means of which he relieved a girl, who was suffering from severe hysteria, of her various symptoms. The idea occurred to him that the symptoms were connected with impressions which she had received during a period of excitement while she was nursing her sick father. He therefore induced her, while she was in a state of hypnotic somnambulism, to search for these connections in her memory and to live through the "pathogenic" scenes once again without inhibiting the affects that arose in the process. He found that when she had done this the symptoms in question disappeared for good.

This was at a date before the investigations of J. M. Charcot and Pierre Janet into the origin of hysterical symptoms, and Breuer's discovery was thus entirely uninfluenced by them. But he did not pursue the matter any further at the time, and it was not until some ten years later that he took it up again in collaboration with Sigmund Freud. In 1895 they published a book, *Studien über Hysterie,* in which Breuer's discoveries were described and

an attempt was made to explain them by the theory of *catharsis*. According to that hypothesis, hysterical symptoms originate through the energy of a mental process being withheld from conscious influence and being diverted into bodily innervation (*conversion*). A hysterical symptom would thus be a substitute for an omitted mental act and a reminiscence of the occasion which should have given rise to that act. And, on this view, recovery would be a result of the liberation of the affect that had gone astray and of its discharge along a normal path (*abreaction*). Cathartic treatment gave excellent therapeutic results, but it was found that they were not permanent and that they were dependent on the personal relation between the patient and the physician. Freud, who later proceeded with these investigations by himself, made an alteration in their technique, by replacing hypnosis by the method of free association. He invented the term *psychoanalysis*, which in the course of time came to have two meanings: (1) a particular method of treating nervous disorders and (2) the science of unconscious mental processes, which has also been appropriately described as "depth psychology."

Subject Matter of Psychoanalysis.—Psychoanalysis finds a constantly increasing amount of support as a therapeutic procedure, because of the fact that it can do more for certain classes of patients than any other method of treatment. The principal field of its application is in the milder neuroses—hysteria, phobias and obsessional states—but in malformations of character and in sexual inhibitions or abnormalities it can also bring about marked improvements or even recoveries. Its influence upon dementia praecox and paranoia is doubtful; on the other hand, in favourable circumstances it can cope with depressive states, even if they are of a severe type.

In every instance the treatment makes heavy claims upon both the physician and the patient: the former requires a special training, and must devote a long period of time to exploring the mind of each patient, while the latter must make considerable sacrifices, both material and mental. Nevertheless, all the trouble involved is as a rule rewarded by the results. Psychoanalysis does not act as a convenient panacea (*"cito, tute, jucunde"*) upon all psychological disorders. On the contrary, its application has been instrumental in making clear for the first time the difficulties and limitations in the treatment of such affections.

The therapeutic results of psychoanalysis depend upon the replacement of unconscious mental acts by conscious ones and are operative in so far as that process has significance in relation to the disorder under treatment. The replacement is effected by overcoming internal resistances in the patient's mind. The future will probably attribute far greater importance to psychoanalysis as the science of the unconscious than as a therapeutic procedure.

Depth Psychology.—Psychoanalysis, in its character of depth psychology, considers mental life from three points of view: the dynamic, the economic and the topographical.

From the first of these standpoints, the dynamic one, psychoanalysis derives all mental processes (apart from the reception of external stimuli) from the interplay of forces, which assist or inhibit one another, combine with one another, enter into compromises with one another, etc. All of these forces are originally in the nature of *instincts;* that is to say, they have an organic origin. They are characterized by possessing an immense (somatic) persistence and reserve of power (*repetition-compulsion*), and they are represented mentally as images or ideas with an affective charge (*cathexis*). In psychoanalysis, no less than in other sciences, the theory of instincts is an obscure subject. An empirical analysis leads to the formation of two groups of instincts: the so-called "ego instincts," which are directed toward self-preservation, and the "object instincts," which are concerned with relations to an external object. The social instincts are not regarded as elementary or irreducible. Theoretical speculation leads to the suspicion that there are two fundamental instincts which lie concealed behind the manifest ego instincts and object instincts; namely, (*a*) Eros, the instinct which strives for ever closer union, and (*b*) the instinct for destruction, which leads toward the dissolution of what is living. In psychoanalysis the manifestation of the force of Eros is given the name *libido*.

Pleasure-Pain Principle.—From the economic standpoint, psychoanalysis supposes that the mental representations of the instincts have a cathexis of definite quantities of energy, and that it is the purpose of the mental apparatus to hinder any damming up of these energies and to keep as low as possible the total amount of the excitations to which it is subject. The course of mental processes is automatically regulated by the *pleasure-pain principle*, and pain is thus in some way related to an increase of excitation and pleasure to a decrease. In the course of development the original pleasure principle undergoes a modification with reference to the external world, giving place to the *reality principle*, whereby the mental apparatus learns to postpone the pleasure of satisfaction and to tolerate temporarily feelings of pain.

Mental Topography.—Topographically, psychoanalysis regards the mental apparatus as a composite instrument, and endeavours to determine at what points in it the various mental processes take place. According to the most recent psychoanalytic views, the mental apparatus is composed of an *id*, which is the reservoir of the instinctive impulses; of an *ego*, which is the most superficial portion of the id and one which is modified by the influence of the external world; and of a *superego*, which develops out of the id, dominates the ego and represents the inhibitions of instinct characteristic of man. Further, the property of consciousness has a topographical reference; for processes in the id are entirely unconscious, while consciousness is the function of the ego's outermost layer, which is concerned with the perception of the external world.

At this point two observations may be in place. It must not be supposed that these very general ideas are presuppositions upon which the work of psychoanalysis depends. On the contrary, they are its latest conclusions and are in every respect open to revision. Psychoanalysis is founded securely upon the observation of the facts of mental life, and for that very reason its theoretical superstructure is still incomplete and subject to constant alteration. Second, there is no reason for astonishment that psychoanalysis, which was originally no more than an attempt at explaining pathological mental phenomena, should have developed into a psychology of normal mental life. The justification for this arose with the discovery that the dreams and mistakes (*parapraxes*, such as slips of the tongue, etc.) of normal men have the same mechanism as neurotic symptoms.

Theoretical Basis.—The first task of psychoanalysis was the elucidation of nervous disorders. The analytical theory of the neuroses is based upon three ground pillars: the recognition of (1) *repression*, (2) the importance of the sexual instincts and (3) *transference*.

Censorship.—There is a force in the mind which exercises the functions of a censorship, and which excludes from consciousness and from any conscious influence upon action all tendencies which displease it. Such tendencies are described as "repressed." They remain unconscious, and if the physician attempts to bring them into the patient's consciousness he provokes a *resistance*. These repressed instinctual impulses, however, are not always made powerless by this process. In many cases they succeed in making their influence felt by circuitous paths, and the indirect or substitutive gratification of repressed impulses is what constitutes neurotic symptoms.

Sexual Instincts.—For cultural reasons the most intensive repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive gratifications of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extrauterine existence; it reaches a first culminating point at or before the fifth year (early period), after which it is inhibited or interrupted (latency period) until the age of puberty, which is the second climax of its development. This double onset of sexual development seems to be distinctive of the genus *Homo*. All experiences during the first period of childhood are of the greatest importance to the individual, and, in combination with his inherited sexual constitu-

tion, form the dispositions for the subsequent development of character or disease. It is a mistaken belief that sexuality coincides with "genitality." The sexual instincts pass through a complicated course of development, and it is only at the end of it that the "primacy of the genital zone" is attained. Before this there are a number of "pregenital organizations" of the libido—points at which it may become "fixated" and to which, in the event of subsequent repression, it will return (*regression*). The infantile fixations of the libido are what determine the form of neurosis which sets in later. Thus the neuroses are to be regarded as inhibitions in the development of the libido.

The Oedipus Complex.—There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations; that is, upon the relative strength of the forces concerned. The most important conflict with which a small child is faced is his relation to his parents, the *Oedipus complex;* it is in attempting to grapple with this problem that persons destined to suffer from a neurosis habitually fail. The reactions against the instinctual demands of the Oedipus complex are the source of the most precious and socially important achievements of the human mind; and this probably holds true not only in the life of individuals but also in the history of the human species as a whole. The superego, the moral factor which dominates the ego, also has its origin in the process of overcoming the Oedipus complex.

Transference.—By transference is meant a striking peculiarity of neurotics. They develop toward their physician emotional relations, both of an affectionate and hostile character, which are not based upon the actual situation but are derived from their relations toward their parents (the Oedipus complex). Transference is a proof of the fact that adults have not overcome their former childish dependence; it coincides with the force which has been named *suggestion,* and it is only by learning to make use of it that the physician is enabled to induce the patient to overcome his internal resistances and do away with his repressions. Thus psychoanalytic treatment acts as a second education of the adult, as a correction to his education as a child.

Within this narrow compass it has not been possible to mention many matters of the greatest interest, such as the *sublimation* of instincts, the part played by symbolism, the problem of *ambivalence,* etc. Nor has there been space to allude to the applications of psychoanalysis, which originated, as we have seen, in the sphere of medicine, to other departments of knowledge (such as anthropology, the study of religion, literary history and education) where its influence is constantly increasing. It is enough to say that psychoanalysis, in its character of the psychology of the deepest unconscious mental acts, promises to become the link between psychiatry and all of these other fields of study.

The Psychoanalytic Movement.—The beginnings of psychoanalysis may be marked by two dates: 1895, which saw the publication of Breuer and Freud's *Studien über Hysterie,* and 1900, which saw that of Freud's *Traumdeutung.* At first the new discoveries aroused no interest either in the medical profession or among the general public. In 1907 the Swiss psychiatrists, under the leadership of E. Bleuler and C. G. Jung, began to concern themselves in the subject, and in 1908 there took place at Salzburg a first meeting of adherents from a number of different countries. In 1909 Freud and Jung were invited to the United States by G. Stanley Hall to deliver a series of lectures on psychoanalysis at Clark university, Worcester, Mass. From that time forward interest in Europe grew rapidly; it showed itself, however, in a forcible rejection of the new teachings, characterized by an emotional colouring which sometimes bordered upon the unscientific.

The reasons for this hostility are to be found, from the medical point of view, in the fact that psychoanalysis lays stress upon psychical factors, and, from the philosophical point of view, in its assuming as an underlying postulate the concept of unconscious mental activity; but the strongest reason was undoubtedly the general disinclination of mankind to concede to the factor of sexuality such importance as is assigned to it by psychoanalysis. In spite of this widespread opposition, however, the movement in favour of psychoanalysis was not to be checked. Its adherents formed themselves into an international association which survived World War I, and by 1926 there were psychoanalytic societies in Vienna, Berlin, Budapest, London, Switzerland, the Netherlands, Moscow and Calcutta and two in the United States. There were psychoanalytic polyclinics in Vienna, Berlin and London, and several training institutes were in process of organization. At that time, too, three journals were the official organs of the societies on the continent and in England: the *International Zeitschrift für Psychoanalyse, Imago* (concerned primarily with applications of psychoanalysis to nonmedical fields) and the *International Journal of Psychoanalysis.* (S. Fr.)

Bibliography.—J. Breuer and S. Freud, *Studien über Hysterie* (1895); Freud, *Traumdeutung* (1900), *Zur Psychopathologie des Alltagslebens* (1904), *Drei Abhandlungen zur Sexualtheorie* (1905), *Vorlesungen zur Einführung in die Psychoanalyse* (1916). Freud's complete works have been published in Spanish (*Obras completas*) (1924) and German (*Gesammelte Schriften*) (1925); the greater part of them has been translated into English and other languages. Short accounts of the subject matter and history of psychoanalysis will be found in: Freud, *Über Psychoanalyse* (the lectures delivered at Worcester, Mass.) (1909), *Zur Geschichte der psychoanalytischen Bewegung* (1914), *Selbstdarstellung* (in Grote's collection *Die Medizin der Gegenwart*) (1925). Particularly accessible to English readers are: A. A. Brill, *Psycho-Analysis* (1922); E. Jones, *Papers on Psycho-Analysis* (1923); S. Ferenczi, *Theory and Technique of Psychoanalysis* (1927).

Controversial Literature: Karen Horney, *New Ways in Psychoanalysis* (1939) and *Self-Analysis* (1942); Clara Thompson, "Penis Envy in Women," *Psychiatry,* 6:2, p. 123 (1943); Erich Fromm, "Sex and Character," *ibid.,* 6:1, p. 21 (1943), "Selfishness and Self Love," *ibid.,* 2:4, p. 507 (1939) and "Faith as a Character Trait," *ibid.,* 5:3, p. 307 (1942); Franz Alexander and Thomas French, *Psychoanalytic Therapy* (1946); Franz Alexander, "Psychoanalysis Revised," *Psychoanalytic Quarterly,* vol. 9, p. 1 (1940), *Our Age of Unreason* (1942) and "Indications for Psychoanalytic Therapy," *Bulletin of the N.Y. Acad. of Med.,* 20:6, p. 319 (June, 1944).

Discussion of Controversial Viewpoints: Robert Waelder, "The Problem of Genesis of Psychical Conflict in Earliest Infancy," *Internat. Jour. of Psychoanalysis,* vol. 28, p. 406 (1937) and "Present Trends in Psychoanalytic Theory," *Bulletin of the Menninger Clinic,* vol. 8, p. 1 (1943); Fritz Wittels, "Neo-Adlerians," *Am. Jour. of Sociology,* vol. 15, p. 433 (1939); Ludwig Jekels, "Psychoanalysis and Dialectics," *Psychoanalytic Review,* vol. 28, p. 228 (1940); Ernest Jones, "Review of Alexander's 'Our Age of Unreason,'" *Internat. Jour. of Psychoanalysis,* vol. 24, p. 90 (1943); H. Hartmann and E. Kris, "The Genetic Approach in Psychoanalysis," *Psychoanalytic Study of the Child,* vol. 1 (1946). (S. Fr.; X.)

Later Developments.—The above article appeared in 1926. It was written by Freud and translated by Ernest Jones. Except for the omission of certain general topics to which Freud alludes, it represents clearly the status of psychoanalytic theory at that time.

The 26 years between 1926 and 1952 were marked by an uninterrupted expansion of psychoanalytic activity in England and the United States. Before the nazis came into power there were active psychoanalytic societies in the U.S.S.R., Japan, Italy, France, Czechoslovakia and Hungary, as well as Germany and Austria; but with the eruption of fascist-nazi governments most of these societies were suppressed, many of their scientific leaders were killed in concentration camps, and all who could escape migrated to other countries. An effort was under way in the post-World War II period to rebuild these societies, their training institutes and their clinics.

At the end of 1951 there were in the United States alone 12 psychoanalytic societies, with a total active membership of more than 500 physicians, and more than that number in training in institutes recognized by the American Psychoanalytic association. There were two societies in South America, one in Australia, one in the British Isles, two in the Netherlands, two in France, a society in India, one in Sweden, one in Switzerland, one reopened in Austria and one in Hungary. What had happened to the two societies which formerly existed in Japan was still a question.

During the totalitarian period the continental journals were suppressed, but in the same period several additional psychoanalytic journals came into existence. Among these were the American *Imago,* the *Psychoanalytic Review,* the *Psychoanalytic Quarterly, Revue française de psychanalyse, Revista de Psicoanálisis* (Argentina) and one in Italy; and such closely related journals as *Psychosomatic Medicine* and *Psychiatry.*

Implicit in Freud's 1926 article are the lines along which both theoretical and technical developments were to occur in the subsequent years. These can be outlined in general terms as follows:

1. The topographical schema of psychological organization, which Freud then emphasized, gradually dropped into a position of relatively less importance. This was largely a result of the influence of Freud's own later writings, in which his attention shifted to more dynamic problems. (*See* Freud, *Hemmung, Symptom, und Angst* [1926; translated into English in 1936, under the title *Problem of Anxiety*]; also Anna Freud, *The Ego and the Mechanisms of Defence* [German, 1936; English, 1937].)

2. The role of anxiety and of the conscious and unconscious defensive measures which the ego utilizes in dealing with instincts and anxiety came to occupy a central position in analytic thinking.

3. These developments were related to a growing interest in the psychoanalytic study and treatment of the child. Starting with the early reports of Freud, Hug-Hellmuth and Jung, child analysis was systematically developed by Anna Freud, Melanie Klein and others, especially in Vienna and London. (*See* Anna Freud, *Einführung zur Kinderanalyse* [1927]; Melanie Klein, *Psycho-Analysis of Children* [1932].)

4. Special problems concerning female sexuality became objects of intensive investigation by Freud, Ernest Jones, Helene Deutsch, Jeanne Lampl-de Groot, Ruth Mack Brunswick, Sandor Rado, Karen Horney and others.

5. Psychoanalytic theory and technique were applied increasingly to the study of organic physiology and pathology. These studies of the interrelationship between organic and psychic processes are exercising a profound influence on medical education and on the everyday practice of surgery and internal medicine. (*See* Edward Weiss and O. S. English, *Psychosomatic Medicine* [1943]; Flanders Dunbar, *Emotions and Bodily Changes* [1935] and *Psychosomatic Diagnosis* [1943]; "Psychosomatic Medicine Monographs"; and the files of the journals *Psychosomatic Medicine* and the *Psychoanalytic Quarterly*.)

6. Psychoanalytic technique and theory have come into wide use in field work in anthropology and sociology: Geza Roheim, Margaret Mead, B. Malinowski, Abram Kardiner, J. Dollard and others.

A survey of certain of these and of other developments will be found in Freud's *New Introductory Lectures on Psycho-Analysis* (1933).

Areas of Controversy.—It is instructive to look back on the controversies which have revolved around psychoanalytic theory and technique. Early schisms occurred over such issues as the basic role which Freud ascribed to biological instinctual processes in human psychology. Jung moved away from this in a direction which was in essence mystical. Otto Rank reverted to an 18th-century facultative will psychology. Alfred Adler placed an unbalanced emphasis on an artificially isolated power drive. Of necessity these viewpoints entailed a rejection of psychoanalytic technique as well as theory, and the supporters of these psychologies did not designate their theories as psychoanalytic, but used various other names (individual psychology, analytical psychology, etc.) to distinguish them from Freud's psychoanalytic psychology. None of these three early separations resulted in the development of a systematic school of theory, technique, experimentation or instruction. The result was that their adherents were gradually disappearing.

More recent controversies are over details of theory or technique and do not lead to a complete departure from the parent stem. The leaders continue to subscribe to the main body of psychoanalytic thought and to look upon themselves as psychoanalysts. Although their right to do so is disputed by some, it is significant that they prefer to be known as "neo-Freudians," rather than as "anti-Freudians."

The more valid among the controversies current at mid-20th century focus on such questions as the definition of instincts, details of libido development and the relative importance of infancy, puberty and adolescence in the genesis of neurosis; and on such technical issues as the duration and continuity of treatment and the handling of transference phenomena. Certain specious issues are often interwoven confusingly with these legitimate issues, however. Some of these are reminiscent of the ancient battles over heredity versus environment, and take the form of polemics over what is called a "genetic" *versus* a "cultural" origin of neuroses, as though it were possible to isolate the influence of the one from that of the other. Such pseudo-controversies are scientific catchpennies, and because they are devoid of meaning quickly disappear.

Disagreement is essential to the growth of any science. In the state of psychoanalysis at mid-century one might deplore only a tendency on the part of some critics to broadcast theoretical concepts widely to a lay public before they have been sufficiently tested. This creates a furor of verbal disagreements and makes it difficult to maintain an atmosphere of quiet objective research. It seemed doubtful, however, that any of the issues which were in dispute at that time would lead to the development of new schools or to such schisms as occurred in earlier years.

Influence on Literature and Art.—The two principal figures in the history of psychoanalysis and modern art were Sigmund Freud and Carl G. Jung. Of Freud's work, the most important for literature and the other arts were *The Interpretation of Dreams* (1900), *Three Contributions to the Theory of Sex* (1905), *Beyond the Pleasure Principle* (1920) and a number of the essays and papers in *The Collected Papers of Sigmund Freud* (the English translation published 1924). Conspicuous for their influence on the arts among these last were such essays as "The Dynamics of the Transference" (vol. ii), "Turnings in the Ways of Psychoanalytic Therapy" (vol. ii), "The Moses of Michelangelo" (vol. iv), "The Relation of the Poet to Day-Dreaming" (vol. iv) and "The Unconscious" (vol. iv). The work of Jung best known to modern writers and artists included *Psychology of the Unconscious* (1916), *Psychological Types, or The Psychology of Individuation* (1920), *Modern Man in Search of a Soul* (1931) and several essays which attempted to explain the psychology of art; of these, his "Psychology and Poetry" (which appeared in *Transition*, translated by Eugene Jolas, in 1930) is perhaps best known. A number of other pioneers in the establishment of psychoanalysis in the 20th century contributed to the very large body of work on psychology and the arts. Most of these followed through suggestions made originally by Freud and Jung, but they also investigated more exhaustively subjects that were for the most part only peripheral to the major interests of the two leading spokesmen for the field. Among these psychoanalysts who were interested in the application of their disciplines to the arts and to criticism were Wilhelm Stekel, Otto Rank, Ernest Jones and Charles Baudouin. The most important works of these men were Rank's *The Incest-Motive in Poetry and Legend* (1912), Jones's *Hamlet and Oedipus* (1910 and 1949) and Baudouin's *Psychoanalysis and Aesthetics* (1924). In addition, there were numerous critics whose analysis of the arts was strongly marked by their preoccupation with psychoanalysis and psychiatry: among them the most influential were Herbert Read, Kenneth Burke, Frederick C. Prescott and Maud Bodkin. Psychoanalytic investigations of the lives of writers and artists were responsible for a large body of additional work. Freud himself contributed to this kind of writing in his *Leonardo da Vinci: A Psychosexual Study of an Infantile Reminiscence* (1910) and in his essay "Dostoyevsky and Parricide" (English translation published in *Partisan Review*, fall, 1945). In both cases, Freud attempted to find in the work of

the artists evidence that would help toward an understanding of their "psychic life." Biography, following upon the suggestions contained in these contributions and others, as well as the great body of clinical investigation, developed a special approach toward the arts, in which the work of art was related to and explained in terms of the artist's psychological history. Conspicuous examples of this form of psychobiography were René Laforgue's *The Defeat of Baudelaire: A Psycho-Analytical Study of the Neurosis of Charles Baudelaire* (1931), Saul Rosenzweig's "The Ghost of Henry James" (in *Character and Personality*, Dec. 1943), Edmund Wilson's biographical studies of literature (many of them contained in *The Wound and the Bow*, 1941), Joseph Wood Krutch's *Edgar Allan Poe: A Study in Genius* (1926) and Van Wyck Brooks's biographies of Mark Twain (*The Ordeal of Mark Twain*, 1920) and Henry James (*The Pilgrimage of Henry James*, 1925).

The question of the influence—of the degree of it and of all the peculiarities of its nature—is as complex as the influence itself is varied and widespread. There were writers and artists who professed to have and sometimes had a great knowledge of psychoanalysis and who worked in terms of a direct recognition of its value for their art. These included most of the surrealists, some of whom (like André Breton) had had actual experience as analysts, and other writers who (like Ludwig Lewisohn, Georg Groddeck, H. R. Lenormand) spoke of psychoanalysis with varying degrees of accuracy and conviction. Of Lenormand's plays, beginning with *Le Mangeur de rêves* (1922), those which presented tragedy based chiefly on psychoanalytic knowledge of character included *L'Homme et ses fantômes* (1924), *Asie* (1931) and *Pacifique* (1937); all these works reflect wide and accurate acquaintance with the discipline and the conclusions of psychoanalysis, though Lenormand objected to their being labelled "Freudian." Also included in this first group of writers was Thomas Mann, who not only knew and greatly respected the work of Freud, but was also extremely judicious in his application of this knowledge to his fiction. In an essay on "Freud's Position in the History of Modern Thought" (1928; included in *Past Masters, and Other Papers*, 1933), Mann applauded Freud for his intelligent concern with the psychic life as well as his wish to find new sources of cure and therapy. One of Mann's first uses of his wide acquaintance with psychoanalysis was in the novel *The Magic Mountain* (1924), but here the reference to psychoanalysis is mixed with a generous and eclectic use of many other kinds of knowledge and speculation—notably the philosophies of Arthur Schopenhauer and Friedrich Nietzsche. That he remained objective concerning the advantages of analysis for modern society was abundantly indicated in such remarks from the novel as this made by the character Settembrini: "Analysis as an instrument of enlightenment and civilization is good, in so far as it shatters absurd convictions, acts as a solvent upon natural prejudices, and undermines authority. . . . But it is bad, . . . in so far as it stands in the way of action, cannot shape the vital forces, maims life at its roots. . . ." (*The Magic Mountain*, Thomas Mann, p. 283 Mod. Library Ed.; A. A. Knopf, Inc., N.Y., 1927.) In his fictional reconstruction of the biblical story of Joseph, Mann quite deliberately made use of the speculations of both Freud and Jung concerning the value of myth and its symbolic recurrence, through a racial (or "collective") unconscious. Mann's fiction showed the skill of an intellectually disciplined mind whose application of psychoanalysis, as well as of other knowledges, never allowed it to dominate but made it serve the original aesthetic form and subject.

The knowledge of psychoanalysis also led modern novelists to establish the analyst himself as an important fictional personage, sometimes available to satirical observation (as in Waldo Frank's novel *The Bridegroom Cometh*, 1938), sometimes placed in a crucial role as adviser and "physician of the soul" (as in Lewisohn's *The Island Within*, 1928) and sometimes credited with providing the means of a novel's resolution (as in Arthur Koestler's *Arrival and Departure*, 1943). The substance and content of psychoanalytic disclosures (or their equivalents in the artist's imagination) often dominated the content of works of literature. Reliance upon the revelations of the subconscious mind was conspicuous in such works as the fiction of Anaïs Nin; surrealist poetry, prose and painting; Groddeck's *Der Seelensucher* (1922); F. Scott Fitzgerald's *Tender Is the Night* (1934); Conrad Aiken's *Great Circle* (1933), *King Coffin* (1935) and much of his poetry (particularly *The Coming Forth by Day of Osiris Jones*, 1931); and both the poetry and fiction of Dylan Thomas. Notable for its literary approximation of clinical analysis was the novel by Italo Svevo (Ettore Schmitz) *La Coscienza di Zeno* (1924; translated as *The Confessions of Zeno*, 1930), in which the narrative is presented as a continuous self-analysis by the hero.

A second group of writers and artists included those who undeniably showed the influence of psychoanalysis but who resisted the labels "Freudian" and "psychoanalytic." These people gained prominence in literature and art in one of two ways: either they formulated their own theories of the unconscious and other psychoanalytic concerns in an effort to disprove Freud or to discount his values; or their work followed the lines and treated of the material with which psychoanalysis was largely concerned without having derived from a study of it. An important opponent of psychoanalysis was D. H. Lawrence; his novel *Sons and Lovers* (1913) interested psychoanalysts and critics who found a direct influence in its presentation of familial problems. Lawrence's reply was to repudiate psychoanalysis as too narrowly and harmfully scientific; but in the energy of his protest lay an earnest of the contribution made by psychoanalysis to his thinking. In a great number of letters and essays, Lawrence attacked both Freud and Jung, though he gave a qualified approval of another analyst, Trigant Burrow. His principal long attacks on psychoanalysis were *Psychoanalysis and the Unconscious* (1921) and *Fantasia of the Unconscious* (1922). In these works, Lawrence accused psychoanalysis of putting a false and debilitating emphasis upon scientific probing and examination which not only misunderstood the vital sources of human action but helped to defeat human vitality and tended to reduce the "life forces" to objects of intellectual curiosity. These reflections were associated in a large portion of Lawrence's writings of every kind with a general attack upon modern rational and intellectual life, as well as with his repudiation of the mechanistic, life-defeating impact of modern industry upon human vitality. Other writers offered in their work tempting opportunities for critics who wished directly to attach the label "Freudian" to them, but in large part rejected it or confessed to an ignorance of the disciplines that had allegedly influenced them. Among these writers were Sherwood Anderson and Eugene O'Neill; particularly in some of the latter's plays (especially *Mourning Becomes Electra*, 1931) there is abundant evidence of his realization of psychoanalytic techniques and discoveries, though O'Neill himself denied any direct line of influence. Franz Kafka was a special case: many of his writings show a line of relationship to his own familial circumstances, revealed especially in "Letter to My Father"; but, while critics did quite successfully exploit that relationship, Kafka's work derived from a complex of other influences which made a too-simple psychoanalytic explanation misleading. (See *The Kafka Problem*, edited by Angel Flores, 1946).

The final kind of influence concerned the role which psychoanalysis played in a number of the major preoccupations of modern writing and art. Psychoanalysis could rightfully claim a share in the motivating influence upon the release (of literature chiefly, but of the other arts as well) from the restraining and inhibiting cultural and traditional limits of taste and decorum which had fairly well held until the end of World War I. In the literature following upon the conclusion of that war (and sometimes antedating it) a greater frankness concerning sexual relationships, familial and infantile sources of perversion and inversion, and the fact of perversion itself became a dominating characteristic. In this connection, the clinical studies begun by Freud and revealed in *Three Contributions to the Theory of Sex* and other places had a rather important voice, though by no means an exclusive one; the work of other psychologists, of sociologists and anthropologists was equally important, and the general impact of the war served as a primary cause of the release of inhibitions among artists regarding the treatment of these matters. What psychoanalysis did was immensely to extend and partly to provide phraseology for the discussion of sex matters or for their dramatization in works of literature. The attitude toward psychoanalysis on this level of influence was often largely undiscriminating, amateurish and ignorant. The principal terms and the popular notions of psychoanalysis were used over and over again in the popular and semipopular literature of the 1920s, as the Marxist and pseudo-Marxist ideas found their way into the work of the 1930s. The catalogue of works which reflected this type of influence is very great; the use of psychoanalysis was sometimes very shrewd, sometimes quite mistaken and misleading and often merely the result of a desire to be fashionable. In one way or another the work of the following writers showed the widespread impression made by psychoanalysis upon the modern world: Floyd Dell, Max Eastman, Maxwell Bodenheim, Conrad Aiken, Susan Glaspell, Evelyn Scott, Waldo Frank, F. Scott Fitzgerald, Carl Van Vechten, May Sinclair, J. D. Beresford and Aldous Huxley. In the work of most of these, psychoanalysis was little more than incidentally acknowledged, or was used merely as a form of intellectual small change. In the 1940s psychoanalysis penetrated even further into the public consciousness and became one of several sources of material, plot, explanation and motivation in the cinema or in novels written at least partly with an eye to an adaptation to cinema production.

The actual study of psychoanalytic influence on modern literature and art contains many varied problems. In the first half of the 20th century at least, the influence was often haphazard and incidental, and art borrowed from it a means of confusing its terms and its disciplines. Until the time of World War I, the career of psychoanalysis had been largely handicapped by a considerable rejection of it as a valid psychology. The writer or artist, aware of a significant new contribution to human knowledge, even in the early years, was both distrustful and confused concerning its actual value for him. New terms, discoveries, emphases (or extensions of original terms) served to confuse him further. In addition, the sources of information from which the artist was able to draw were often quite remote in both nature and quality of precision from the original; as psychoanalysis became popular, numerous books, essays, editorials, conversations and amateurish "games" served often to give portions of "information" or vagrant notions of what psychoanalysis was actually doing. This variety of circumstance accounted for the vast majority of errant and erroneous uses of what was, when separated from its accurate source, mostly a fashionable mode of discourse, or a jargon.

For those who considered psychoanalysis seriously and with some accuracy, it made substantial contributions in at least three separate areas of creative work. The first of these was the study of the un-

conscious itself—often quite aside from the psychoanalytic purpose for making that study. The pioneering influence in this connection was Freud's *The Interpretation of Dreams*. His investigation of the "dream work" had a profound and widespread effect upon the arts, especially as it gradually made available to artists certain information concerning the "behaviour" of the unconscious. The dream not only provided an extension of the uses to which the various languages of the arts might be put; it also suggested a range and a new reordering of symbolism which could be applied in varied ways to literature and art. In literature, the technique known as stream-of-consciousness writing was greatly extended through adaptations or applications of Freud's original suggestions. A considerable range of literary styles was made possible as a consequence, as well as new departures in the structure of novels, plays and poems. The popularity of this method was largely the result of the great success of James Joyce's *Ulysses* (1922), imitated in a great number of the novels which followed its publication. *Ulysses* was followed by *Finnegans Wake* (first published in part as "Work in Progress" in the magazine *Transition,* 1927 to 1929; as a book, 1939), a much more elaborate and exhaustive exploitation of the literary resources of psychoanalysis, in combination with many other disciplines, knowledges and techniques available to the erudition of its author. Other applications of the information about the unconscious made available to the arts included the so-called "automatic writing" of the surrealists, especially of André Breton, Louis Aragon, Philippe Soupault, René Crevel and Paul Éluard. These artists, and others, did not confine themselves, however, to a mere simulation of mental disorders in their work; it did remain close to what the founders of surrealism thought were their psychoanalytic origins. Breton's definition of surrealism, given in the *Manifestes du surrealisme* (1924) established both the nature and the limitation of their work: "Pure psychic automatism by which it is intended to express, verbally, in writing, or by other means, the real process of thought. Thought's dictation, in the absence of all control exercised by the reason and outside all aesthetic and moral preoccupations." (André Breton, *Manifestes du surrealisme,* p. 46; Éditions du Sagittaire, Paris, 1924). In its later development, the sponsors of surrealism acknowledged that such work could easily be confined to a too narrow and repetitious form of creation and proposed (in Breton's essays and in those of Nicholas Calas) to free themselves from the limits of psychoanalytic descriptions of the unconscious. This independence of the limits of clinical psychoanalysis was much less true of surrealist painting (Max Ernst, Yves Tanguy, Salvador Dali and others), which for the most part continued to realize pictorially and without much variation the desires resident in the unconscious.

The second most conspicuous contribution made by psychoanalysis to modern literature and art had chiefly to do with the re-examination and exposition of human behaviour and the motives underlying it. This revision of view, involving as it did much attention to a person's sex life and his relationship to his parents from infancy on, did much to encourage both illuminating and wildly erroneous changes in the explanation of motive. In fiction and drama it encouraged a certain boldness in the presentation of issues hitherto generally suppressed in literature. Many of the explanations offered in novels and plays were naïvely crude or overly simple. So too the extensions of psychoanalysis found in biography were marked often by crude and simple applications to speculative readings of their subjects.

The range of information concerning such mental disorders as were available, to novelists and dramatists especially, increased as the techniques of psychoanalysis expanded and theorists multiplied. Earlier fiction of the 1920s often remained content to speak superficially of "repressions," "neuroses" and "free association" and to narrate visits to psychoanalysts as part of a social fashion. As familiarity with psychoanalysis increased, the use of it became more "professional" in its efforts to achieve clinical exactness. The novels, dramas and motion pictures of the late 1930s and of the 1940s demonstrated much detailed knowledge of psychiatry and a willingness to exploit its opportunities for characterization and melodrama. An early example of literature engaged in such exploitation is Fitzgerald's *Tender Is the Night,* whose major theme depends upon the risk taken by a promising young American psychoanalyst when he marries his patient, and is thus forced to call increasingly upon his reserves of nervous and moral energy until both are completely exhausted. The novel revealed a considerable acquaintance with the terminology, practices and techniques of the clinic and the sanitarium, and some skill in appropriating them to the problems of a novel's form and structure.

The third contribution is largely the work of Jung. The difference between his influence and Freud's can best be explained by reference to their differing explanations of the term "libido." Freud had used this term to designate sexual energy; Jung preferred to expand its definition. Linked with this fundamental difference of interpretation was the much greater emphasis Jung put upon what he called the "collective unconscious," which has been described as "the precipitate of humanity's typical forms of reaction since the earliest beginnings." (J. F. Jacobi, *The Psychology of Jung,* p. 8; Yale University Press, New Haven, Conn., 1943.) The role of the artist became extremely important for Jung; he was considered a form of priest of the "collective unconscious" because he relates the conscious life of his fellows to its archetypes in the unconscious. This view of the unconscious and of its availability to art and literature had no small influence upon 20th-century writers and artists. It was one of several germinal theories which stimulated a great critical interest in myth and mythology. Among the critics whose interpretations of literature showed its influence were Maud Bodkin (*Archetypal Patterns in Poetry,* 1934), Elizabeth Drew (*T. S. Eliot: The Design of His Poetry,* 1949) and Richard Chase (*Quest for Myth,* 1949). Jung's influence served in a way to counteract Freud's rather narrow view of the artist and the tendency of his followers to analyze art in terms of the artist's psychic nature. Jung was in a much larger sense concerned with the act of creation and with its significance as a restatement and reshaping of recurrent mythical themes.

At the halfway mark of the 20th century, the usefulness of psychoanalysis for criticism and its influence upon the artist had grown much more complex and varied than at the beginning. New explorations of Freud and Jung continued to appear, as well as a considerable number of studies by psychoanalysts of the arts, by critics of psychoanalysis and psychiatry. In literature especially, the groundwork of psychoanalytic knowledge was accepted as familiar to the majority of both artists and critics.

(F. J. HN.)

PSYCHOGALVANIC REFLEX. The term psychogalvanic reflex (P.G.R.) was first used by Veraguth to describe the change in electrical properties of the human body (or any living animal body) in response to nocuous (emotional) stimuli. The terms "galvanic skin reflex," "skin constrictor reflex" and "sweat secretion reflex" have been used synonymously. This reflex is usually demonstrated in one of two ways. (*a*) Electrodes connect the hands directly to a galvanometer. When the subject is stimulated by a pin prick, threat of injury, etc., the galvanometer, after a latent period of about two seconds, will show a deflection indicating a change in the difference of potential between the two hands. This rises to a maximum within two to ten seconds and subsides in about the same time. (*b*) The human subject forms the fourth arm of a balanced Wheatstone bridge electrical circuit. On stimulation the galvanometer will deflect as described above. In this case, the deflection indicates a change, usually a decrease, in the ohmic resistance of the body.

This phenomenon was first described by Vigouroux (1879). It remained, however, for Veraguth (1909) to draw the attention of a large scientific audience to the psychogalvanic reflex. The physics of the "reflex" is still a matter of dispute. According to Gildemeister it is the result of a change in conductivity of the human body which is dependent upon polarization of the membranes of the cells of the skin, so changing the cellular permeability to different ions. The anatomical control of the psychogalvanic reflex has been shown to lie in the sympathetic nervous fibres which lead to the smooth musculature of the walls of sweat glands and capillaries. Any stimulus resulting in activity of the sympathetic division of the autonomic nervous system will consequently result in changes in tonicity of the involuntary musculature of the skin surfaces of the body which are shown by the secretion of sweat, changes in circulation, local skin temperature, etc. This combined action leads in turn to variations in electrical conductivity (psychogalvanic reflex).

Psychologists have, for a long period, been interested in this phenomenon, particularly following the suggestion of Binswanger (1907) that *only* emotional stimuli elicit the reflex. This view has been held by many subsequent investigators. The work of Radecki (1911) and later of Aveling questions the validity of this assumption. It is probable that the psychogalvanic reflex is elicited most frequently by nocuous stimuli, but that it is not specific to "emotional" situations.

The reflex has found application in many fields of research. Otologists have used it to detect the feigning of deafness in dubious cases. Psychoanalysts have used the phenomenon together with word association tests as a means of discovering

hidden complexes. Many investigators have made use of the psychogalvanic reflex for the demonstration of individual differences in emotionality. There seems to be fairly good evidence that such differences may be established in this fashion. Psychiatrists have made use of the reflex in differential diagnosis of organic and functional orders.

Attempts toward the practical application of the reflex as an indicator of emotional stability of men who were applying for positions in hazardous occupations have not met any great success.

PSYCHOLOGICAL TESTS. A psychological test may be described as a measurable sampling of an individual's performance on a standard task. "Test" is also used to designate the printed form or other instrument used in the testing process. Sampling implies that the person's test performance is taken as typical of some aspect of his usual behaviour, which we call a trait or an attitude; or, if he has been motivated to do his best, some aspect of his performance at its maximum; *i.e.*, some ability. Tests are often called scales, indicating that they measure and describe a single psychological variable in terms of some kind of quantitative unit; but not all psychological measuring scales are tests (*e.g.*, rating scales, or those used in laboratory experiments); it is customary to restrict the term "test" to some performance measure of individual differences, and the branch of psychology which deals with them and the results obtained by their use is called differential psychology (*q.v.*).

Historical Development of Tests.—Individual differences in mental performance were first scientifically studied in the 1870s and 1880s by Francis Galton, who endeavoured to demonstrate mental inheritance by making estimates of the abilities of distinguished (and other) fathers and sons and establishing the relationship between family strain and ability. His associate and successor, Karl Pearson, developed a method of measuring such relationships by means of the coefficient of correlation, a technique which came to be of primary importance in test research and standardization. In the late 1880s J. M. Cattell, inspired by Galton's work and trained in experimental methods under Wilhelm Wundt, devised a series of performance tasks he called mental tests, and with them he and his associates obtained objective measures of several mental processes such as association, memory span, reaction time, perceptual discrimination of various kinds, etc.; however, no one was able to demonstrate high correlation between scores on these tests and any measures of school ability. The first successful test of school aptitude was the general intelligence test of Alfred Binet, who at Paris in 1905 assembled and used a series of problem-solving tasks, differing from Cattell's in that they measured complex rather than elementary operations, including the "higher" processes of abstraction and generalization. These tests Binet soon organized into a mental-age scale which he used effectively in predicting pupils' school success or failure. The Binet tests were soon translated and widely adopted; several U.S. revisions appeared, most used of which have been those of Frederick Kuhlmann (1912, 1922) and L. M. Terman, whose Stanford revision appeared in 1916 and was revised in 1937.

During World War I group tests of intelligence were administered to about 1,750,000 men, and the decade of the 1920s witnessed a rapid multiplication of intelligence and special aptitude tests as well as of educational achievement tests and their widespread adoption in education and industry for purposes of predicting success in school and employment. That decade brought also the development of attempts to measure traits of personality other than abilities, by means of questionnaires, performance tests, rating scales and other devices. During the 1930s test workers both in laboratories and in practical service became increasingly critical as to what tests actually measure, not merely how consistently they do it. This attitude led to refinements of statistical techniques of test construction and standardization, to increasingly numerous validation studies and to the development of factor analysis techniques (first suggested by C. E. Spearman in 1904), by means of which the various mental functions involved in tests of general intelligence and other traits can be identified with some assurance. Thus, when World War II began, psychologists were prepared to put into use many kinds of tests on a large scale for selecting the special aptitudes needed in various branches of the military, naval and air services.

The number and variety of kinds of psychological tests are very large. One bibliography of psychological tests and rating scales listed 4,279 such instruments, classified under 85 categories. In terms of the functions measured, psychological tests can be grouped into three broad classes: (1) tests of aptitudes, either general or specialized; (2) tests of achievement or proficiencies, educational, vocational or other; and (3) tests of other personality traits, attitudes and interests.

Aptitude Tests.—Aptitude tests differ from proficiency or achievement tests in that the latter measure the outcomes of formal education or occupational training while the former measure potential abilities, untrained except through incidental practice and experience or prerequisite background education. Aptitudes vary in inclusiveness from tests of highly specialized functions, such as cancelling all a's on a page or speed of tapping with a stylus, to comprehensive tests of abstract or mechanical intelligence. Special aptitude tests are most extensively used in employee selection and placement, in detecting peculiarities or defects in sensory, motor or intellectual capacity and in experimental research on the nature and organization of abilities. At first such tests were commonly designated by the kind of mental condition or process presumably involved, such as colour blindness, auditory acuity, controlled association (opposites, genus-species, etc.), memory span, imagery, reasoning or hand coordination; but the later tendency was to designate them by the kind of operation involved, pitch discrimination, assembling, form board, tapping, arithmetical problems, series completion or other, or else by their proposed use, such as clerical aptitude, reading readiness, lathe operation or medical aptitude. Aptitude tests may employ simple equipment such as a list of questions or arithmetic problems, or a page of pied type for cancelling a's, or relatively elaborate apparatus for testing some complex mechanical aptitude.

When a rating on general level of ability rather than special aptitudes is desired, several different tests may be combined into a scale which purports to measure general intelligence or general mechanical aptitude. The latter type is represented by several tests, some paper-and-pencil tests, some performance tests, which endeavour to get at some general organic capacity more fundamental than the various special motor skills. Unfortunately, agreement as to the definition and nature of "mechanical aptitude" has been lacking, with the result that some tests emphasize one ability, some another, including such varied things as motor dexterity, comprehension of mechanical principles, acquaintance with a variety of mechanical devices, facility in visualizing shapes or movements, numerical skill, etc. Consequently, while such tests have been used with considerable success in vocational guidance and selection, they have yielded lower correlations than are desirable, both with one another and with such external criteria of mechanical aptitude as are available.

Individual Intelligence Tests.—General intelligence tests are known also as tests of abstract or verbal intelligence, mental alertness and scholastic aptitude. They may be individual (given to one subject at a time) or group tests. The former include tests of the Binet (mental-age) type and performance (nonverbal, manipulative) tests. In any Binet-type scale the tests are grouped as to degree of difficulty. Thus, the Revised Stanford-Binet had 122 test items grouped into 20 levels of difficulty, 6 being placed at each half-year or year level from age two up to three superior adult levels, except for eight at the average adult level. The nature of the tests is suggested by the following examples: (1) Year V: defining orally (by description, classification or use) 2 words from a standard list of 45, copying a square, repeating a standard sentence from memory; (2) Year X: reading and summarizing a paragraph, telling what is absurd

about a picture, naming 28 words in one minute; (3) average adult: transcribing into a simple code a short message, defining 20 words from standard list, stating differences between two abstract words. The mental age which the subject achieves is computed by totalling the credits for all tests passed (or presupposed), usually at the rate of two months' credit each. A given mental age is defined as the level of test performance which is median or normal for children of that age. The intelligence quotient, popularized by Terman although originally suggested by William Stern, measures rate of mental growth, and is obtained by dividing the mental age by the chronological age (omitting decimal point). If a 10-year-old has a M.A. of 10, his I.Q. is 10/10 = 100; if his M.A. is 8, his I.Q. is 8/10 = 80; if his M.A. is 12, his I.Q. is 12/10 = 120. Thus, 100 I.Q. designates exact normality, I.Q.s above 100 indicate degrees of brightness above average and I.Q.s below 100 indicate degrees of dulness below average. An I.Q. of 70 or below is usually regarded as indicating some degree of mental deficiency. Since an individual's I.Q. does not usually vary greatly from year to year, it affords a basis for predicting his probable future achievement; its value for school placement is therefore apparent. Because the average individual's performance does not increase beyond the average adult level in the scale (approximately mental age 15), 15 is arbitrarily taken as the chronological age in computing the I.Q. of an individual above that age.

Performance scales, such as the Pintner-Paterson, Grace Arthur and others, were originally designed for illiterates, non-English-speaking and the deaf (for whom language is highly artificial); they employ such nonverbal material as form boards, dissected pictures, mazes, picture completions and sequences and painted cubes to be arranged to form given designs. The Bellevue-Wechsler scale for adults combines five verbal tests with five performance tests; this and other performance scales yield point scores, although mental ages and I.Q.s can be computed by the use of tables. Special scales have also been devised for testing the blind, partially sighted and those otherwise handicapped.

Group Intelligence Tests.—The earliest group intelligence tests were the Army Alpha (for literates) and Beta (for illiterates) used in World War I. In World War II these were replaced by the Army General Classification test. Group testing previously had been assumed by most psychologists to be too unreliable a method for successful use, but after 1918 it quickly achieved popularity and many group tests were standardized not only for adults but for use in colleges and high schools and in elementary and primary grades. For the last-named, nonverbal tests (which do, however, use oral directions) are provided, using pictures, designs, mazes, etc., to be marked as directed. Some scales, such as the Kuhlmann-Anderson, provide a graded series from infant to adult level, so that scores at successive testings can be directly compared. Other tests have endeavoured to encompass the entire age range in one test, but usually at some sacrifice of reliability. Verbal group scales brought into popularity so-called "objective" questions, which are answered by checking the correct one of a number of answers, hence called the "best-answer," "multiple-choice" or "recognition" type of question, or in some other way recording an answer that is unambiguously scored right or wrong independently of scorers' variable judgments. Typical of such questions are the following:

What is related to a cube in the same way in which a circle is related to a square? (underline one) *Circumference, Sphere, Corners, Solid, Thickness* (analogies test).

The opposite of treacherous is . . . (underline one) *Friendly, Wise, Brave, Cowardly, Loyal* (opposites test).

If a strip of cloth 24 in. long will shrink to 22 in. when washed, how many inches long will a 36-in. strip be after shrinking?——— (arithmetical reasoning).

On the two blanks write the two numbers that should come next: 2 3 5 8 12 17 — — (number series completion).

A number of devices have been provided to facilitate the administering or scoring of tests and thus extend the range of their usefulness. The cyclical or spiral form, instead of grouping items of the same kind, follows one or two examples of one kind by one or two of another kind, so that each type recurs several times in the scale, usually at a more difficult level; this is also called the self-administering type, since it can be given by an untrained examiner. Quick-scoring or self-scoring devices on several tests permit wrong answers to be quickly distinguished from right without recourse to laborious item-by-item scoring; while machine-scored answer blanks, separate from the test booklets, are extensively used when a number of tests have to be scored.

Most group tests have a time limit such that none or at most very few of a group can solve all problems within that time, thus preventing accumulation of many undifferentiable high scores. Such tests therefore measure not only mental power but also speed. Most Binet tests, on the other hand, are untimed; hence they measure power and only slightly speed.

Primary Abilities.—One of the most hotly debated questions has been that of the nature of general intelligence (*q.v.*). Is it, as some have held, merely the overlapping area of the many highly specialized abilities involved in more complex performances? Or is it, as Spearman argued, a single, common factor (symbolized by *g*) which is a component of many tests, always combined with some special *s* factor? Spearman devised a special correlation analysis for supporting his view and for demonstrating the presence or absence of the *g* component in a group of tests. This *g* he postulated as a special kind of energy which is used in discerning abstract relationships and drawing inferences. Later a third intermediate view was developed; namely, that there are besides *s* factors a number of "group factors" or "primary abilities" less inclusive than Spearman's *g* but more general than the identical elements of the first-mentioned view. By multiple factor analysis of tables of intercorrelations between tests, the number of factors which will account for these correlations can be ascertained, and by examining those tests which are heavily or lightly loaded with a given factor, its psychological nature can be identified with some assurance. Among the primary abilities there have been identified verbal comprehension (V), number facility (N), space visualization (S), word fluency (W), perceptual speed (P), inductive thinking (I), memory (M) and some others with less certainty; a number of these abilities have already been further analyzed into less general factors. No assumption was made as to the psychophysiological nature of these factors. General intelligence, in this view, is a name given to one or another combination of primary abilities, and the fact that some intelligence tests do not correlate more highly than they do with others is in large part because different tests emphasize different abilities. Thus, performance scales which are heavily loaded with form board and other spatial tests will emphasize the S factor; while a highly verbal test will be heavily loaded with V and W factors; and still another may have a large proportion of N. As an outcome of these analyses, tests are available which measure separately the primary abilities in relatively pure form, thus giving better knowledge of just what is being tested than is obtainable from an inclusive general intelligence score or mental age.

Proficiency or Achievement Tests.—Tests of proficiencies, also called achievement tests, are intended to measure outcomes of systematic education and training in school or occupation toward a conventionally accepted pattern of skill or knowledge. There are other fields in which definite proficiencies are sufficiently recognized, such as sports and the fine arts, so that informal if not formal achievement testing is practised. Some writers make a distinction between psychological tests and educational tests; but this distinction is one of practical convenience rather than of method or even of functions measured, for both kinds of test employ common principles in their construction and standardization, while both inherited capacity and practice influence the scores on all kinds of tests.

Only the principal types of educational achievement tests and their functions will be enumerated here. They are: (1) subject tests, in reading, language usage, arithmetic, geography, writing, algebra, chemistry, Spanish and a score of other school subjects, are available literally by the hundreds; they may yield point scores or a "reading age," "arithmetic age" and the like; or (2) several subject tests may be combined into an achievement battery for measuring general school proficiency either in point scores or "achievement ages" and perhaps "accomplishment quotients" (AA/CA); some achievement batteries are available for use either as such or broken up into subject tests; (3) classification or placement tests are subject tests standardized for the uses indicated by the names; (4) promotional tests cover a limited scope, usually one topic or unit of instruction or a term's work in the subject; (5) instructional tests are planned as teaching and study aids; (6) diagnostic tests are designed to reveal special difficulties, such as "borrowing" in subtraction, in order to facilitate corrective instruction; (7) survey tests, used in school surveys for evaluating the work of schools and school systems instead of individual pupils, are usually briefer and cover the fundamental subjects only. Besides these types of achievement tests, special types of scholastic aptitude are measured by (8) readiness tests (usually reading readiness) for first-grade pupils and (9) a variety of subject aptitude tests, such as foreign language, music, mechanical or fine arts, or at preprofessional levels, for law or medicine, to predict a student's fitness for undertaking the study of these subjects.

Tests of occupational achievement are exemplified by the more than 100 trade tests standardized during World War I to aid in selecting the most proficient men for the civilian occupations represented in large army cantonments, such as typist, telegraph operator, stationary engineer, sheet metal worker, truck driver, etc. They were of three types, question, picture-question and performance, and their scores classified men into expert, journeyman, apprentice and novice grades of skill. These tests were not used extensively in civilian life because industries large enough to need tests in selection routine seldom hire craftsmen skilled in these broad trade categories; instead, they employ specialized workers, often trained on the job, and hence selected by means of aptitude tests. Some large firms do, however, maintain their own trade-test departments for constructing, standardizing and administering proficiency tests for their highly specialized operations.

Personality Tests.—The first test of traits of personality other than abilities to attract general professional attention was the Downey Individual Will-Temperament test in 1919. Using as material the changes in handwriting under varying stimuli and instructions, it yielded profile scores on a dozen motility traits. It did not enjoy long popularity because of its low reliability (which was due to brevity of the component tests) and low correlation with trait ratings; but it did stimulate activity in this field of testing. Several other performance tests were used chiefly for research purposes, for measuring honesty, co-operation, inhibition, aggressiveness, persistence, dominance and other traits. But most of the attempts to measure traits of personal

adjustment have employed schedules or inventories, lists of questions to be answered "yes" or "no," such as, "Do you often feel lonesome even when others are around you?" "Do you often feel just miserable?" The prototype of these inventories was the Woodworth Personal Data sheet, for measuring neurotic symptoms, begun but not actually used during World War I. Special forms of questionnaire, for measuring neurotic tendencies, introversion-extraversion, ascendance-submission, school, family, home or personal adjustment, and several multiphasic inventories in which several traits can be measured at once by using separate scoring keys for each trait have been published and extensively used. Since these instruments are personal reports rather than tests, their value is limited both by the subject's ability and his willingness to give a true and competent report about himself; and they have, in general, considerably lower statistical reliability (and hence validity) than have ability and achievement tests. They have proved fairly helpful in clinical diagnosis and vocational guidance, more so than in employment and other situations where the subject feels he has something at stake in choosing how he shall respond.

A special type of adjustment test that acquired wide clinical use was the projective method, of which there are several examples. They are based on the principle that a subject, responding to an unstructured stimulus situation, will "project" his own feelings and attitudes into his response. They employ standard words, pictures or other materials, and the subject is given only very general directions, such as, "Give the first word that comes to mind," or "What might this (ink blot or cloud picture) be?" or "Tell me a story about this picture" or "Make anything you like" (with these paints, modelling clay, toys). The word-association tests of C. G. Jung and of Grace H. Kent and A. J. Rosanoff, the ink blots of the Rorschach test, Stern's cloud pictures, the pictures in the Murray Thematic Apperception test, the psychodrama (of J. L. Moreno and others, in which the subject dramatizes with the aid of others his own problem situation), finger painting, toy objects and dolls, and play therapy are among the vehicles of self-expression which give opportunity for the subject to reveal, sometimes unwittingly, his own problems and ambitions. Most projective tests have not been quantitatively scaled, or only incompletely so, and are diagnostic devices rather than measuring instruments.

A variety of verbal-response instruments has been devised for measuring directional sets toward particular goals or objects, designated as attitudes, opinions, interests, values, etc. Opinions about particular social policies, propositions or groups have been measured by checking agreement with one or more of a list of varied opinions to which scale values have been assigned by the "method of equal appearing intervals" (Thurstone attitude-scale technique) or by expressing degree of agreement or disagreement with a proposition (Likert technique). These have been used chiefly in social research as to what attitudes are held and how they are changed. The measurement of vocational interests has been undertaken by means of several tests, best known of which was that of E. K. Strong, Jr., which consisted of 400 items to be checked *like, dislike* or *indifferent;* and the degree of resemblance of an individual's pattern of interests to the pattern found characteristic of each of the 30 or more standard occupational groups is taken as a measure of his interest in (but not necessarily aptitude for) that occupation. Nonvocational interests and values were measured by the Kuder Preference record, the Allport-Vernon Scale of Values and other devices. The Allport-Vernon yields a profile showing the relative strength of six "values": the theoretical, economic, aesthetic, social, political and religious. These instruments have found their principal use in personal and vocational guidance.

Units of Measurement.—Measurement implies representation of a selected variable along a linear scale divided into units of equal magnitude. In psychological measurement, defining and equating these units presents peculiar difficulties. The simplest procedure is to count each problem solved or each question correctly answered (or, in adjustment tests, "favourably" answered) as one point and total them to obtain the point score. Or, in case of speed tests, the time required to perform the task or the amount accomplished in a given time can be taken as the measure. Such point scores are of course somewhat arbitrary, for items vary in difficulty and importance; and various methods have been proposed for differential weighting of items. Any "raw score," moreover, varies in significance from test to test, so it is necessary to provide norms or comparison scores in order to evaluate an individual's test performance. The simplest norm is the mean score of a standard comparison group, which must be large enough (several hundred cases, preferably) to be statistically stable and typical of the population it is taken to represent, ordinarily a particular age group, occupational group or school grade. To permit more precise interpretation, quartile, decile or centile norms are often provided.

Raw scores are often supplemented or replaced by some kind of derived or equivalent score, either mental age or some form of dispersion score. A mental age, since it is the median test performance of a given age group, incorporates norms directly into the age units, as do also the various educational or achievement ages. This practice is feasible so long as the ability measured increases with age. But since the average person's intelligence-test performance ceases to improve after 15 ("average adult level"), mental ages above that do not conform to the definition but are arbitrary scores; although on the Revised Stanford-Binet they yield I.Q.s of approximately the same significance as in earlier years. Consequently, many psychologists hold that mental ages and I.Q.s of the more intelligent half of the adult population are logically unsound, and should be replaced by some kind of dispersion score.

Dispersion scores describe an individual by defining his position somewhere along a representative distribution of scores when arranged in order from low to high. His centile score (commonly called percentile rank, or P.R.) is the percentage of the comparison group whom he equals or surpasses; thus a P.R. of 75 means that he equals or excels 75% of the group, while the remaining quarter surpass him. But since in any normal group psychological test scores tend to pile up in the middle of the range and become decreasingly frequent toward either extreme (the normal probability or Gaussian distribution), equal differences in P.R. do not at all ranges mean equal differences in test performance; for this reason it is sometimes denied that P.R.s are "units." This objection is avoided by the use of the standard score, based not on rank but on actual scores. The standard score is expressed as a fraction or multiple of the standard deviation unit of the dispersion (one S.D. or sigma is the square root of the sum of the squared deviations of each individual score from the mean score). A person whose score is exactly at the mean of the group does not deviate from it, hence has a standard score of 0; one who scores one sigma below the mean has a standard score of −1.00, and in a normal population his P.R. would be 16, since a range of ±1 S.D. includes approximately 68% of the population (16 P.R. to 84 P.R.). Thus, a single derived score both states and interprets a test score.

Test Construction and Standardization.—Constructing and standardizing a test is much more than merely choosing the kind of task to be performed and devising questions or problems; that is only a first step. In addition: (1) Many details of construction have to be worked out, tried and revised, items must be evaluated and those discarded which do not contribute to the desired differentiation, time limit set, verbal directions and mode of presentation of material formulated, scoring instructions worked out, key prepared, etc. (2) A well-standardized test must also have known reliability, as high as possible; that is, it must be demonstrably self-consistent in measuring whatever it measures; to this end self-correlation procedures are employed. (3) A well-standardized test must be provided with adequate norms, as previously described; it often happens, however, notably with educational achievement tests, that the test administrator prefers to compute his own local norms rather than use published norms. (4) Finally, a test cannot be considered thoroughly standardized until something about its validity is known; *i.e.*, what it actually tests or what it is good for, as indicated by a reasonably high correlation between scores and some independent criterion of whatever characteristic it is thought the test will discriminate or predict—a question which obviously can never be completely answered.

To say a test has high validity means that it correlates well with one of three types of criterion: (1) some accepted measure of the trait or ability the test purports to measure, usually some kind of rating of a group of subjects on that trait; (2) some other test already assumed to be a valid measure of the trait, which merely pushes the problem back upon the earlier test and ultimately back to the first type of criterion (thus, many early group tests were announced as valid tests of intelligence because they correlated well with Binet mental ages, whose validity as a measure of intelligence can also be questioned); (3) some criterion of the actual effectiveness of the test in making desired discriminations or predictions. Inasmuch as the first two criteria hinge on what raters mean subjectively by a given trait name and take into account when they make ratings on it, the increasing tendency is to disregard trait names and test titles and rely on the last-named type of criterion—school records, industrial production records or other concrete evidence of achievement or character.

The validation of already standardized tests for a given purpose (such as selecting employees or soldiers for a particular job) is an application of the third type of criterion named. It constitutes a well-established experimental procedure which may be briefly summarized in the following eight steps: (1) analysis of the operation to determine its psychological characteristics and requirements; (2) choosing, devising or adapting presumably suitable tests for experimental tryout; (3) selecting a group of suitable experimental subjects (those for whom some criterion measure is available or can later be obtained); (4) obtaining efficiency criteria on those subjects (production record, scholarship record, efficiency ratings or other); (5) obtaining scores of those subjects on all tests to be experimentally evaluated; (6) correlating each set of test scores with criterion measures; (7) selecting (and perhaps combining) those tests showing best correlation; (8) setting critical scores on those tests, for selection or rejection, and using those tests with their critical scores in selecting or rejecting candidates.

Uses of Psychological Tests.—As already indicated, psychological tests have found a wide variety of practical uses in many areas of activity. The diversity within a single field is suggested by the following partial list of uses of aptitude tests in schools and colleges: pupil classification and placement; as aids in selective admission; diagnosing causes of failure or substandard performance; homogeneous sectioning of classes by ability to facilitate effective instruction; educational and vocational guidance; recommending for employment or for admission to higher institutions; selection for special responsibilities or special treatment. The uses of different kinds of educational achievement tests have already been summarized. But in addition to

their practical uses, psychological tests have come to be hardly less important as tools of fundamental research on theoretical problems in psychology, social sciences and even physiology, typical of which are the following: course of mental growth and decline in both general and special functions; evaluation of the relative role of hereditary and social determinants of ability and personality; measurement of effects on individual abilities, traits, and attitudes of various organic, physical or social changes; evaluation of group differences in ability and temperament between different races, nationalities, sexes, age groups, socio-economic classes, etc.; analyzing the nature of mental organization and the interrelations between mental functions.

Psychological tests were no longer thought of by informed observers at mid-20th century as in the fad stage, although they were and always would be in the experimental stage. Nor are they devices which can successfully be applied by anybody, regardless of professional training and qualifications. Tests can be and often are misused and misinterpreted by those who lack sufficient psychological training and insight to appreciate their meanings and limitations, and to be able to interpret single test scores wisely in the light of other relevant facts about the personality of the individual being examined. The administration and interpretation of tests, and even more their construction and standardization, are professional undertakings, requiring extensive and intensive professional training; they are no tasks for amateurs.

PSYCHOLOGISM, in philosophy, is the view that problems of epistemology (that is, problems relating to the validity of human knowledge) can be solved satisfactorily by the psychological study of the development of mental processes. Locke's *Essay on the Human Understanding* may be regarded as the classic of psychologism in this sense. A more moderate form of psychologism only maintains that psychology should be made the basis of other studies, especially of logic.

PSYCHOLOGY is (1) the study of mind and of mental phenomena. That is the historical use of the term, a use that has been valid ever since the 17th century, when René Descartes, the dualist, drew the distinction between matter as extended substance and mind as unextended substance. (*See* PSYCHOLOGY, HISTORY OF.) This Cartesian view tends to turn psychology into the study of immediate experience, experience regarded in its own right as it comes directly to the conscious individual. Psychology thus finds itself describing experiences and formulating the laws under which experience is determined by its physical and physiological conditions.

(2) In the 20th century the scope of psychology was enlarged to include all the integrated action of the total individual, human or animal. Thus, modern psychology includes within itself the science of human behaviour, where behaviour is taken to mean the action or conduct of the whole person. Physiology deals with the action of separate organs or bodily systems and is thus closely related to psychology and not always to be distinguished from it.

In general, it may be said, human psychology studies the whole person—his thoughts, his conduct and also those properties of him which make him think and act as he does. For this reason, psychology is concerned with both consciousness and behaviour, each because it is important in its own right. Behaviour, however, gains additional importance since language, a special form of behaviour, is the sole means by which the consciousness of men can be revealed to the observing scientist.

SCHOOLS OF PSYCHOLOGY

Scientific psychology, partly because of its heritage from philosophy, of which it was for a number of centuries a part, has tended to become divided into schools, which differ from one another in respect of their beliefs about the primary purpose of this science. The most important schools that have played a prominent role in the history of 20th-century psychology are the following.

Physiological Psychology.—Wilhelm Wundt (1832–1920), who is regarded by some as the founder in the 1860s of the new experimental psychology, fixed the name physiological psychology upon this new science by the publication of his *Grundzüge der physiologischen Psychologie* in 1874. For 40 years the 6 editions of this systematic handbook both assessed the new psychology and fixed its scope. Thus, in the 19th century physiological psychology came to mean the experimental school as opposed to the nonexperimental methods of those philosophers who were writing about psychology, and, more narrowly, as opposed to the intentionalism of Franz Brentano (*see* below). In the 20th century physiological psychology is a field and not a school, the field of all psychologists who extend their investigations beneath the skins of the organisms studied. (*See* general section *Physiological Psychology,* below, p. 687.)

Introspectionism.—The psychology of immediate experience used the method of introspection for getting at the contents of consciousness. Wundt fixed this method upon the German psychology of the 19th century, and E. B. Titchener (1867–1927) upheld it in the United States. Until about 1915 it was regarded as the chief method for the study of human psychology.

Basically introspection consists merely in having the observing subject report and describe the contents of his consciousness—sensations, images, feelings, perceptions, intentions, ideas, thoughts and insights. There are, however, many cautions to be observed and many technical procedures to be followed in order to get complete descriptions. The school of introspectionism may be said to have died out with the deaths of Wundt in 1920 and of Titchener in 1927 and with the concomitant rise of behaviourism and other objective systems. On the other hand, report on the contents of consciousness still remained an important method of psychology, as, for instance, in psychoanalysis (*q.v.*). (*See* also CONSCIOUSNESS; INTROSPECTION.)

Intentionalism.—The act psychology, which Franz Brentano (1838–1917) got from the Scholastic philosophers and promoted in his *Psychologie vom empirischen Standpunkte* in 1874, constitutes an intentionalism because it represents mind as comprising mental acts which are by intention directed upon some object. *Seeing* is a mental act which must have some object, like *green.* The seeing is said to "intend" the green, which "inexists" within the seeing, being the "immanent object" of the seeing. Brentano's influence, great in Austria and Germany, also affected British psychology markedly. James Ward (1843–1925) followed Brentano's leadership, whereas G. F. Stout (1860–1944) followed Ward, and William McDougall (1871–1938) espoused a purposive psychology that was consistent with this tradition. No important U.S. psychology belonged within this school, except in certain respects the psychology of William James (1842–1910).

Functionalism.—The school of functional psychology flourished in the United States at The University of Chicago for a dozen years or more from 1896 on. Although it owed something to William James, it may be said to have been founded by John Dewey (1859–1952), supported by the Chicago philosophers G. H. Mead and A. W. Moore and headed by James R. Angell (1869–1949). Functional psychology was stimulated by the prevalent interest in Charles Darwin's views and the theory of evolution, for it holds that mind is to be understood in terms of the use it has for the individual in his struggle for survival. The chief function of mental phenomena is held to be "accommodatory"; *i.e.,* directed toward the successful adjustment of the organism to its environment.

This psychology of use, the psychology of the "is-for," is related to pragmatism (*q.v.*), the "functional philosophy" developed by C. S. Peirce, James and Dewey. Functional psychology considers both consciousness and behaviour, since both kinds of events can be understood as of use to the organism.

Functional psychology as a school disappeared in the furor over behaviourism (*q.v.*) sometime near 1915, but as a point of view it continued to be characteristic of U.S. psychology, as it had been since the start of the American "tradition" about 1890. The U.S. temperament has been practical and competitive.

The pioneers in the new continent struggled with nature, and their descendants continued a culture that is largely competitive. Democracy is the arena in which competition is free and unbiased. Such men need to assess their own capacities and their fellows', and psychology furnishes them with the means of assessment.

Thus the mental test, which measures differences in human capacities, thrived in the U.S. after having been invented in England by Francis Galton, Darwin's cousin. James McK. Cattell (1860–1944) supported a functional psychology of capacities at Columbia university, New York, N.Y., for 25 years, and indeed it is hard to find much U.S. psychology in the first half of the 20th century that was not concerned with the capacities, abilities or aptitudes of the individual, human or animal, to achieve some kind of success, whether the goal be the discrimination of colours, the finding of food in a maze with minimal errors and effort, or Albert Einstein's sudden insight into the significance of the relativity of movement. (*See* PSYCHOLOGY, HISTORY OF: *Functional Psychology.*)

Behaviourism.—Functionalism prepared the way for the school of behaviourism, which was founded by John B. Watson (1878–) about 1913. Watson complained that introspection had not advanced psychology, that its results were unreliable, and that psychology ought to ignore the existence of consciousness and deal only with behaviour. He had been working with animals, and with animals the functional capacities are fairly easily determined, whereas the inferences as to the nature of the animal's accompanying consciousness are uncertain and seemingly unimportant. Why not, he asked, take a suggestion from animal psychology, and limit human psychology also to the study of behaviour?

For a dozen years behaviourism dominated the U.S. scene in psychology, although there were many individual variations on the basic formula. When behaviourism encountered phenomena that are essentially introspective in nature, like perceptions and images, usually it simply substituted verbal report for introspection.

Since the data of consciousness have to be reported to be known, it is always possible to regard the behavioural report as the observed datum, thus reducing conscious phenomena to the behaviour of speech or writing. In this way behaviourism anticipated operationism (*see* below; *see* also BEHAVIOURISM).

Gestalt Psychology.—Contemporaneous with behaviourism was the German school of Gestalt psychology. Like behaviourism it represented a revolt of a younger scientific generation against the established conservatism of introspectionism. Its founder was Max Wertheimer (1880–1943), who was supported by Wolfgang Köhler (1887–) and Kurt Koffka (1886–1941). This movement, which dated from a paper of Wertheimer's in 1912, stressed the importance of considering parts only in relation to one another and the wholes which they form. It thus makes large use of what is called field theory; *i.e.*, theory formulated in terms of the simultaneous dynamic interdependence of all parts within a whole. It admits both consciousness and behaviour into psychology, but opposes their analysis into conventional units or elements. The leaders of Gestalt psychology all migrated to the United States after Adolf Hitler came to power in Germany, and there they had the effect of lessening the influence of introspectionism, which is based on the definite assumption of mental elements, and of behaviourism, which excludes consciousness from consideration.

Thus, the Gestalt psychologists tend to oppose the operationists who are the modern behaviourists. (*See* PSYCHOLOGY, HISTORY OF: *Gestalt Psychology.*)

Dynamic Psychology.—In the 20th century the growing concern of psychology with motivation and the springs of human action was traceable partly to Sigmund Freud (1856–1939) and psychoanalysis (*q.v.*) and partly to William McDougall's insistence on the importance of instincts in social behaviour. There was no clearly recognized, self-conscious school of dynamic psychology, but the importance of the field was fully appreciated. The psychology of motives, since it aims at predicting human action, is intensely practical because it furnishes explanations of human nature. Thus, dynamic psychology supports and is supported by the American interest in functionalism. It is consistent with Gestalt psychology, as is apparent in the work of Kurt Lewin. It is not inconsistent with behaviourism, as the contributions of E. B. Holt and E. C. Tolman have shown. It carries on, moreover, the protest against the static analyses of an introspectionism which never got around to treating the problem of motivation adequately. (*See* PERSONALITY; PSYCHOANALYSIS.)

Operationism.—In 1927 P. W. Bridgman, the U.S. physicist, pointed out that physical entities have no meaning except in terms of the operations by which they can be observed, and that a scientific hypothesis which cannot be tested by certain definite operations is meaningless, a pseudo problem. The psychologists were quick to seize upon this notion that entities can be defined by the operations for observing them, because such logic allowed them to define immediate experience in terms of the data of the report of the experience. It is possible in such manner to reduce all psychological phenomena to observable physical terms, substituting behavioural for conscious data. Some psychologists who favour these reductions to behavioural terms have called the practice operationism. The procedure turns out to be closely allied to the logical positivism of the Vienna philosophers such as Moritz Schlick, Rudolph Carnap and Herbert Feigl. It has also been called physicalism and behaviouristics. It is a much more sophisticated philosophic position than the original behaviourism which sought mostly to ignore consciousness instead of accounting for it in physicalistic terms. Operationism embraces consciousness and then reduces it to observable physical data, thus bringing psychology, by making it physical, within the unity of the sciences, an achievement which is one of the goals of the logical positivists.

Operationism is opposed to the Cartesian dualism of introspectionism and also to the more modern dualism implied in the theories of Gestalt psychology. Its insistence on the reduction of psychological entities to their observational bases is distasteful to Gestalt psychologists, who believe that such reduction violates the integrity of immediately observable phenomena. There is, however, no conflict between operationism, on the one hand, and functional and dynamic psychology, on the other. Operationism, moreover, *is* behaviourism made philosophically palatable. It follows that the modern dichotomy in systematic psychology lies between operationism, which includes behaviourism, and phenomenology, which includes Gestalt psychology and the other psychologies that deal with immediate experience without reducing it to the operations by which it is observed.

Experimental Psychology.—Originally experimental psychology was regarded as a school because it grew up in opposition to the nonexperimental psychology of the philosophical writers. Later, under Wundt's influence, experimental psychology came to mean human, adult, normal, generalized psychology—not animal, nor child, nor abnormal psychology, nor the psychology of individual differences. While that usage persisted, it was confusing because all fields of psychology claimed to use the experimental method. Properly speaking, experimental psychology is no longer a school but another name for scientific psychology, which appeals to experiment whenever possible.

(*See* EXPERIMENTAL PSYCHOLOGY; PSYCHOLOGY, HISTORY OF.)

GENERAL PSYCHOLOGY

The term "general psychology" is used to designate the generalized facts and principles of normal psychological phenomena and functions. Being general, general psychology excludes the psychology of individual or group differences; thus, it excludes child psychology, abnormal psychology and comparative psychology as well as differential psychology. At one time general psychology could be identified with the general principles of normal human adult psychology, but later, when it became plain that most of the principles of human learning can be investigated by the use of animal subjects, the restriction of general psychology to human subjects was ignored, and the analogy of general psychology to general physiology, which treats of functions

without regard to specific or individual differences, became exact.

The more usual main subdivisions of general psychology are (1) sensation and perception; (2) reaction and sensory-motor co-ordination; (3) learning, inheritance and thought; (4) feeling, emotion and motivation; and (5) personality, including intelligence and the specific abilities.

Sensation.—The study of the capacities of the organism for sensory discrimination was the chief topic of research by the experimental psychology of the 19th century. This early start for the researches on sensation, taken together with what proved to be the fruitfulness of the experimental method in the field, resulted in the accumulation of such a large body of information that any general psychological compendium of facts is bound to be weighted heavily with the facts and laws of sensation.

Usually this field is divided, according to Aristotle's classical distinctions, into five subdivisions: sight, hearing, smell, taste and, finally, the body sensations, which are sometimes grouped together under the general term of somaesthesis. Somaesthesis includes all sensory phenomena that arise from stimulation of the skin and the tissues underlying it, the muscles, tendons and joints, the viscera, and the vestibule and semicircular canals of the inner ear.

Sensory problems are also sometimes divided in accordance with the four principal attributes of sensation: quality, intensity, extensity and duration. The study of sensory *quality* resulted, for example, in the various laws of colour vision and in both the analysis of auditory experience into pitches and the working out of the laws of the interrelations of pitches. The chief result of the study of sensory *intensity* has been the establishment of the way in which sensitivity varies with the strength of stimulation, a relationship which was originally called Weber's law when it was thought to be simpler than it really is. The study of *extensity* led to the formulation of laws of shape, size, distance and the interrelationships of all three. The study of *duration* led to a knowledge of the capacities of the organism for the discrimination of intervals of time, from short durations of less than a second up to long durations. These distinctions among attributes cannot, however, be maintained with rigour, since many phenomena involve two or more of the four basic dimensions. Size and brightness are related in the visual perception of small objects. Space, time, brightness and even hue may come under consideration in working out the laws of visually perceived movement. (*See* AUDITION; FECHNER'S LAW; HEARING; ORGANIC SENSATIONS; PSYCHOPHYSICS; SKIN, SENSORY FUNCTIONS OF; SMELL AND TASTE; VISION OR SIGHT; WEBER'S LAW.)

Perception.—The study of perception became merged with the study of sensation, but originally perception was distinguished from sensation by its function of objective reference. The adequate account of sensation was held to be given by the description of immediately given experience that arises on stimulation of the sense organs, whereas perception, always conceived as based upon sensation, was regarded as giving information about the external world and the nature of the stimulating objects. To experience a visual pattern of black lines on a white ground is sensation; to recognize it as a drawing of a familiar face is perception.

Nineteenth-century psychology often devoted its chapters on sensation to the consideration of sensory quality and intensity, whereas it dealt with the patterning of sensation in respect of space and time in the chapters on perception—a distinction that is doubtless rooted in Immanuel Kant's conception of space and time as categories in respect of which other data are organized, but a distinction that did not in general prove useful to psychology.

Reaction.—The behaviouristic trend of modern psychology, as it appears successively in functionalism, behaviourism and operationism, tends to make reaction the central theme of psychology, displacing the sensory processes which were focal to introspectionism. A reaction is response to stimulation, and a response is usually muscular movement or glandular secretion, although in some animal species there are other end products of nervous action which may also be counted as responses.

The study of reaction times is as old as experimental psychology; the reaction experiment was first set up by astronomers (1858) in their attempt to determine fixed individual differences in the observation times of astronomical observers. Stimulus-response (S-R) psychology dated from John Dewey's inauguration of functional psychology in 1896.

Dewey made it clear then that psychologists cannot afford to limit their attention to stimulation or to response but must look primarily to the significant relationships between stimulus and response. After all a stimulus is not a stimulus unless it elicits some kind of response, and a response is not a response unless it is elicited by some kind of stimulation.

This S-R psychology was favoured by the growth of physiological psychology, by the study of reflexes and by the discovery of the conditioned reflex (*q.v.*).

Learning.—Under the topic of learning come all the ways in which the behaviour or thought of the individual, all the S-R relationships of the organism, are modified, except for those modifications that are predetermined at the time of conception by the basic biological inheritance of the individual. The growth and development of the individual are fundamentally dependent upon inheritance, although the precise ways in which they are manifested may be learned. An infant does not learn to be adolescent, nor a youth to be senile; each has to grow up to a later genetic stage. A child *learns* to walk, but *inherits* the capacity to walk—the legs, muscles and possibilities of nervous co-ordination. It is well recognized that there is no behaviour in which both inheritance and learning have not played essential roles.

The effort to separate the effects of heredity and environment, to separate "nature" from "nurture," in Francis Galton's phrase, is foredoomed to failure, except that the respective contributions of nature and nurture may be assessed in particular performances, often by studies upon the comparative resemblances of identical twins, fraternal twins, brothers and sisters who are not twins and persons with no special community of inheritance.

The experimental investigation of learning, which began with Hermann Ebbinghaus' famous experiments on memory, published in 1885, expanded to provide the principal laws of the memorizing and forgetting of materials consciously learned, of skills voluntarily acquired, or habits involuntarily fixed in conditioned responses, and of new knowledge acquired in the solution of problems. For all of this work both human and animal subjects have been used. The general principles applicable to human subjects have proved to be discoverable from work upon animals, which can be taught to acquire skills or to solve problems, or which can be "conditioned," as the phrase is. The conditioned response, discovered by I. P. Pavlov in 1903, consists in the establishment of an association between two stimuli, such that one stimulus gives rise to the response that was already the normal consequent of the other stimulus.

For instance, Pavlov, sounding a bell whenever he presented food to his dogs, found that the dogs, whose saliva normally ran at the sight of the food, learned to salivate at the sound of the bell before they saw the food. Some of these conditioned responses seem to be established without the learner's conscious appreciation of the process that is taking place and without his intention to learn, but later investigations showed that insight and motivation are prevalent in animal as in human learning and are perhaps in some degree essential to all learning.

The learning that takes place in the solving of problems requires *insight* and *thought*. Conversely, it is true that the outcome of successful thinking is usually remembered. For these reasons, thought has almost ceased to constitute a separate chapter in general psychology and has become a special problem of learning. The dependence of thought on motivation and intention has been recognized since the researches of the Würzburg school about 1905, and the use of insight in the quick formation of newly perceived relations has been understood since the rise of the Gestalt school about 1917.

Ebbinghaus established for half a century the current notion

of his day that associations are formed by the continued repetition of the conscious concurrence of the items associated. If you wish to learn a poem or a list of nonsense words, you merely say over and over again what you wish to learn until you have learned it. Similarly the rat learns its way to the food through a maze by repeatedly traversing the correct path. It is, however, no longer clear that mere repetition is a sufficient reason for learning. It seems rather that repetition only furnishes the opportunity for other factors to operate in cementing the new association, factors as yet imperfectly understood by psychologists but related to insight and motivation.

The question has also arisen as to whether *forgetting* depends merely upon the lapse of time after the establishment of learning. It seems more likely that learning decays, when not re-enforced by use, because new learning, which takes place in the elapsed time, interferes with the retention of the old. Certainly the inhibition of past learning appears to be least during sleep, and greatest whenever the opportunity for conflict with new learning is greatest.

(*See* ASSOCIATION, MENTAL; LEARNING; MEMORY.)

Feeling and Emotion.—*Feeling* has long been a prominent chapter in general psychology, a chapter which deals with the laws of hedonic tone, of the pleasantness and unpleasantness of stimulus objects and situations. It has tended to be resolved into the psychology of preferences and thus to become a topic in the general chapter on motivation. The fact that pleasantness and unpleasantness cannot be experienced at the same instant thus reduces to the fact that two objects cannot be preferred, each over the other, simultaneously.

Emotion, while defying precise definition in psychology, has been investigated in its physiological and motivational aspects. W. B. Cannon's emergency theory of emotion makes it clear that, in strong emotion, the body is put in readiness for efficient violent action, with facilitation of those muscular systems which would be used in attack or escape and with inhibition of the digestive and other vegetative functions.

The conditions of emotion are, however, simply special cases of motivation. A few, like fear in falling or anger in restraint, may be largely inherited. The rest depend, it would seem, on learning and conditioning. (*See* AFFECTION; EMOTION; FEELING, PSYCHOLOGY OF.)

Motivation.—It has long been recognized that the realization of particular stimulus-response relationships is dependent upon the *attitude* or *intention* of the subject at the time of stimulation. Ludwig Lange in 1888 found that the preparatory attitude may change reaction time in such an amount that the longest times are almost twice the shortest. In 1905 Narziss Ach showed that the whole pattern of the reaction consciousness depends on the intentional preparation—a *determining tendency,* he called it. Still later the importance of motivation as a condition of learning was recognized (*see* above). In dynamic psychology it is customary to specify the basic *needs* or *drives* which determine human or animal action, and often to measure their relative strengths under particular conditions, by observing the preference of the subject under conflicting motives. For instance, the strength of hunger in a rat after a known period of food deprivation can be measured by the strength of an electric shock from a grill, laid in the floor of a passageway, that will prevent the rat from crossing the grill in order to obtain food.

(*See* ATTENTION; HYPNOTISM; INSTINCT IN MAN; SUGGESTION.)

Personality.—For the most part the study of personality does not form a chapter of general psychology because it belongs to the special field of differential psychology. We find ourselves more interested in differences in personality from person to person than in those factors which are common to all. On the other hand, the fact that the individual is made up of a pattern of general and special abilities, that his behaviour is dependent upon his particular repertoire of attitudes and beliefs, that the development of his capacity for intelligent adjustment to novel situations increases rapidly in childhood to a maximum which is approached in early maturity—such facts are part of general psychology, and, with the statistical techniques of factor analysis, have assumed a position of primary importance among the fundamentals of psychological knowledge.

(*See* DIFFERENTIAL PSYCHOLOGY; INTELLIGENCE OR UNDERSTANDING; PERSONALITY.)

General psychology also includes the study of what are called the *psychological mechanisms*—the defense and escape mechanisms, rationalization, frustration and all the means by which the individual avoids neurosis and makes his adjustment to the requirements that his environment lays upon him.

(*See* DEFENSE MECHANISMS.)

SPECIAL FIELDS OF PSYCHOLOGY

The scope of modern psychology is indicated by the enumeration of those special fields which, in addition to general psychology, occupy the attention of particular investigators, teachers, writers and professional psychologists.

Physiological Psychology.—The physiological psychologists are those who carry on their researches by actual observation or manipulation beneath the skin of the organism whose reactions are being studied. For the most part they use animal subjects and operative techniques, as in those studies in which the functions of the brain are determined by removing or destroying a portion of the brain and noting the effects upon the behaviour of the animal whose brain has been altered. The rise of endocrinology led physiological psychologists to experiment on the effects of hormones on temperament and motivation, either by the injection of hormones into the blood stream or by the extirpation of the glands which secrete the hormone. So much is known of the physiological substrate of psychological phenomena that it is possible to write a fairly complete psychology in physiological terms.

(*See* section *Physiological Psychology* below for more detailed discussion; *see* also ENDOCRINOLOGY.)

Comparative Psychology.—For the most part comparative psychology consists of the comparative study of the behaviour and psychological capacities of different animal species, from the Protozoa up to the great apes and man. The topics of greatest interest have been instinctual behaviour as it is found in different species, the growth of intelligence throughout the evolutionary scale, and the social habits of certain insects and mammalian groups. Besides this animal psychology, comparative psychology sometimes also includes a comparison of the conduct and customs of human races, tribes and nations—a comparative social anthropology.

(*See* ANIMAL PSYCHOLOGY; INSTINCT IN MAN; PSYCHOLOGY, COMPARATIVE.)

Genetic Psychology.—Phylogenetic psychology is included within the comparative psychology that studies the development of the psychological functions in the evolutionary series. Ontogenetic psychology considers the development of the individual from conception to death. A great deal is known about the prenatal capacities of mammals for discriminative response, perception and movement. The psychology of childhood and adolescence began to receive attention about 1882 and was re-enforced in the 20th century by the importance which psychoanalysis attached to the early formative years of life. Child psychology is really now a special field of psychology, knowledge of which is recommended to all parents. The psychology of adult maturity is taken in charge, for the most part, by general psychology, but the psychology of later maturity and senescence is regarded as a special field, called gerontology. Geriatrics undertakes to assess the capacities which are derived from experience and which do not show marked decay in old age and to indicate the manner in which the aging can most successfully make their adaptations to the limitations which are forced upon them.

(*See* ATYPICAL CHILDREN; CHILD PSYCHOLOGY; PSYCHOANALYSIS.)

Social Psychology.—Social psychology, which is closely allied to sociology and social anthropology, considers the individual in the social structure. It began with the study of the formation of

crowds, groups and mobs, and of the principles that govern group action. It lays stress upon the intrapersonal motives of men, and the basic instincts, needs or drives that determine their action. In this way, social psychology became allied to dynamic psychology and the psychology of personality, and indirectly to abnormal psychology where the variations of personality are exhibited in extreme degrees.

Originally social psychology was forced to develop without much use of the experimental method, but after about 1930 there was an increasing use of "polling" techniques, in which public opinion or the opinions of special groups are sampled in many controlled interviews. The polling technique has also been used to obtain descriptive information about the actual conditions under which the members of a large group live or work. Many of these devices received especial impetus by their extensive use during World War II. For instance, propaganda, a social device for influencing the motivation of large groups, is seldom successful unless based upon a previous knowledge of the opinions and attitudes of the persons to whom it is directed.

(*See* ATTITUDES; PSYCHOLOGY, HISTORY OF: *Social Psychology*.)

Abnormal Psychology.—Originally abnormal psychology, dating from the work of J. M. Charcot in France which began about 1862, was focused upon the behaviour and motivation of insane and neurotic persons. It was the rise of psychoanalysis, more than anything else, that made abnormal psychology the field in which the nature of personality received the most attention, and that broke down the distinction between abnormal and normal psychology, merging them in what ultimately came to be called dynamic psychology (*see* above). The obsessions and compulsions of neurosis turn out to be only extreme and clear-cut forms of the prejudices and habit patterns of the normal person, and the line between the normal and the abnormal is apt to be placed simply at the point where institutional care becomes necessary for the individual who deviates persistently from the social average.

Modern abnormal psychology may be said to include clinical psychology (*see* section on *Clinical Psychology* below; *see* also ABNORMAL PSYCHOLOGY; DELUSION; HYPNOTISM; LIBIDO; PERSONALITY; PSYCHOANALYSIS).

Differential Psychology.—The study of individual mental differences, originally undertaken by Francis Galton about 1883 in his concern for inventorying the mental capacities of the British nation, developed in association with the mental tests which were devised to reveal individual differences among the members of large groups. Differential psychology may be said to complement general psychology, since the latter exhibits averages and generalities, whereas the former shows the variety and variation which occur about the averages. For the most part, differential psychology has been functional psychology, dealing with the capacities of persons to do well in the business of living, especially those capacities which can be quickly measured by psychological tests. Most of the discussion of the relative importance of nature and nurture (*see* above) in determining the character of the adult personality has taken place within the domain of differential psychology, which also provides the basis for the selective techniques of vocational and personnel psychology. The most effective tool for the determination of the dimensions of personality from the results of psychological tests is factor analysis, which reduces multiple test performances to the simplest analytical components. (*See* DIFFERENTIAL PSYCHOLOGY.)

Educational Psychology.—The oldest form of applied psychology is educational psychology. Psychology, the science that studies learning, contains the basic principles that pertain to education. Differential psychology, moreover, supplies knowledge of individual differences in aptitude and intelligence, differences that have to be taken into account if education is to be maximally effective. It was on these grounds that educational psychology got under way in the 1890s, partly under the aegis of G. S. Hall. Modern educational psychology involves the study of the principles and techniques of learning as applied to formal education or as worked out experimentally in the school situation, the study of abilities and aptitudes (especially the aptitude for learning which develops so markedly during childhood and adolescence, being related to intelligence or dependent on it) and the study of the techniques for arousing motivation. Since learning occurs only in so far as it is self-initiated by the learner, teaching consists almost entirely in stimulating motivation and in establishing conditions under which learning is most likely to occur. (*See* section on *Educational Psychology* below.)

Clinical Psychology.—Clinical psychology is the field of applied psychology that undertakes the assessment of personality and the counselling and guidance of persons who need help in their personal adjustments to living. The need for psychological guidance is great. There are child guidance centres, clinics for the behaviour disorders of children, school psychologists who aid in the adjustment of children to the requirements of schooling or of living in general, marriage clinics, psychological counsellors for adults. Thus defined, clinical psychology includes psychoanalysis and borders upon the medical counselling of psychiatrists.

(*See* section on *Clinical Psychology* below; *see* also PSYCHOANALYSIS.)

Vocational Psychology.—The study of the aptitudes, abilities and interests of both children and adults and of the means of assessing these variables by tests and interviews make up the major portion of vocational psychology, which is sometimes called personnel psychology when it is applied to the selection of employees for an industry or business or of men for special services in an army. The task of the vocational psychologist is to evaluate present aptitude and to predict success in the acquisition of skills for some new activity or work. The wide use of personnel selection in World War II increased the use of vocational psychology in the educational and industrial worlds.

Industrial Psychology.—Besides being of use in the selection of personnel for different jobs, psychology is employed in industry to determine the conditions for maximal efficiency in work. Industrial psychology studies the conditions which produce fatigue and monotony, and the most efficient ways to reduce fatigue by the introduction of rest periods, the effect of variety in work, the most efficient work habits, the ways to avoid having accidents.

Industrial psychology also considers the effects on work of temperature, climate, high altitude in aeroplanes, alcohol, tobacco, stimulants and sleep. It is concerned with the design of machines and other instruments for their most efficient use by human operators. A good machine must take into account both the perceptual and motor capacities of the man who uses it. Industry has also become interested in the training of operators, and certain U.S. results show that democratic leadership provided by a foreman produces, because of its motivational value, more rapid learning than an authoritarian attitude. Industrial psychology is also concerned with the problems of labour morale and the securing of efficient social relations between labour and management. (*See* FATIGUE; INDUSTRIAL PSYCHOLOGY.)

Professional Psychologies.—The growth of the applications of psychology after about 1920 was so great that it became necessary to distinguish between scientific psychology and professional psychology. The professional psychologist utilizes the findings of psychological research to render service of one kind or another. He may also engage in his own research, but the line between the investigation of general principles and the rendering of particular service is fairly clear. The foregoing paragraphs mention educational psychology, clinical psychology, psychoanalysis, vocational psychology, personnel psychology and industrial psychology as kinds of professional or applied psychology (*q.v.*). Closely related to clinical and industrial psychology are consulting psychology and business psychology. There is also legal psychology which deals with the many aspects of human nature affecting the operation of law, including the reliability of testimony and the detection of lying. The wide

application of psychology to military problems in World War II led to the recognition of a military psychology, in which all the psychological problems of training, of aptitude selection, of efficiency in work, of motivation and morale, of personal adjustment to normal living and to continued emotional strain are worked over in the military context and brought into the service of the army, navy and air forces.

CLINICAL PSYCHOLOGY

Psychology is the science of human behaviour. Clinical psychology, an applied branch of that science, may be defined as the science, technique and art which deals with the application of psychological principles to the adjustment problems of human beings. Such a definition has several implications for clinical psychology in general, and for clinical methods in particular. It implies: (1) that clinical psychology is concerned with the individual case; (2) that the individual has some problem or difficulty which is disturbing either to himself or to others around him; (3) that both diagnostic and remedial measures are employed in dealing with these human problems; and (4) that clinical psychology is an art as well as a science and technology. It is these aspects which give clinical psychology its uniqueness.

The terms "clinic" and "clinical" are in some respects unfortunate and misleading. They were first used by Lightner Witmer, who in 1896 organized what he called a psychological clinic at the University of Pennsylvania. They are terms borrowed from medicine, where they are used correctly in accord with their Greek origin—meaning bedside—especially the bedside of the sick, or a class taught medicine or surgery by the treatment of patients in the presence of the students. The psychological usage, of course, has no reference either to a bed or the sick or to instruction. A psychological clinic is a place where children and adults go to get some help from a psychologist in the solution of some of their mental and behaviour problems.

The Clinical Problems.—Many attempts have been made to classify the behaviour problems which are seen in the clinic; none with great success. One common method of classification is to divide them into two categories—conduct problems and personality problems. Conduct problems are those which interfere with the rights and behaviour of other people, while personality problems are those which interfere with the personal adjustment of the individual. The former in their extreme manifestations may lead to delinquency and criminal activity, while the latter in an exaggerated form may lead to neuroses or psychopathy. While such classifications may be useful for descriptive or statistical purposes, it is clear that they have little practical or clinical value. Whether stealing, for example, is classified into one or the other depends upon the motivation of the act.

Some of the common problems for which children are referred for clinical diagnosis and treatment were tabulated by Luton Ackerson in a study of the records of 5,000 consecutive cases seen at the Illinois Institute for Juvenile Research. These are listed in the table. The per cent column indicates the number of cases in which a given problem was noted in the record by the psychiatrist, social worker or psychologist who studied the child.

It will be noted from the table that most of the problems seen in the clinic are those which might be described as conduct or personality disorders. There are, however, many other types of clinical problems which the psychologist is expected to handle either alone or in co-operation with a physician or psychiatrist. For example, special methods and techniques are required in dealing with the many difficult social and psychological problems of the blind or partially blind, the deaf and hard of hearing, the physically and mentally handicapped, the spastic, the epileptic, the postencephalitic, the bright child retarded in school, the child with severe reading difficulty, the person with speech difficulties and the person who has difficulty in making an adequate vocational adjustment. All of these require special, clinical methods and techniques which the psychologist is equipped to employ.

Common Problems for which Children Are Referred for Clinical Diagnosis *

Problems	Per Cent
Nervousness, restlessness, irritable temperament	41
Disobedience, incorrigibility, stubbornness, contrariness, defiant attitude	40
Retardation in school	37
Question of feeblemindedness or inadequate intelligence	31
Temper display, tantrums, irritable temperament	31
Dull, slow manner, listlessness, lack of initiative or ambition	30
Stealing	26
Immature childish manner or judgments, impaired judgment	25
Fighting, quarrelsomeness, violence and threatening violence	25
Enuresis or bedwetting beyond third birthday	25
Lying, marked untruthfulness	24
Advice replacement, commitment or institutionalization	24
Poor work in school	23
Crying spells, crying easily	22
Truancy from school	19
Masturbation	19
Truancy from home	18
Sensitiveness or worrisomeness, (general) sensitiveness or worry over some specific fact or episode	18
Bashfulness, shyness	17

*Based on records, 5,000 consecutive cases seen at the Illinois Institute for Juvenile Research.

The Nature and Motivation of Behaviour Reactions.—In order to gain a clear understanding of the methods and procedures used in dealing with the behaviour deviations which come to a psychological clinic, it is necessary to present, first, a brief statement concerning the development of normal behaviour, since the basic mechanisms involved in normal and abnormal behaviour are essentially the same.

One of the principles which has been fairly generally accepted by psychologists is that all behaviour is a form of adjustment whether it be socially acceptable, such as most of man's behaviour is, or socially unacceptable, as are most of the behaviour patterns mentioned in the table. Behaviour is what an organism does in response to some stimulus or complex of stimuli (often called a situation) which acts upon it. Lying, stealing, truancy, quarrelsomeness, disobedience, restlessness, stubbornness, violence, enuresis, masturbation, bashfulness and the many other so-called problems are simply names given to certain ways an organism meets and adjusts to a situation.

A second principle, closely associated with the first, is that most of the behaviour of human beings is learned; that is, it results from the repeated action and reaction between the individual and certain environmental forces. The physiological and psychological processes in this type of learning are the same as those involved in learning to swim or learning to read. The motivation and, of course, the external forces are different. This principle applies to socially unacceptable behaviour just as directly as it does to socially acceptable behaviour; *i.e.*, an individual learns to be honest just as he learns to be dishonest; he learns to lie and cheat and steal just as he learns to be upright and trustworthy; he learns to be unstable as well as he learns to be stable; he learns to be stubborn and disobedient just as he learns to be flexible and obedient.

A third postulate is that both acceptable and unacceptable types of behaviour can be learned only through practice; *i.e.*, by reacting to situations which call forth a certain response. (This is often called the reaction hypothesis.) In other words,

if an individual is to be honest, he must at some time in his experience (usually in early life) have had an opportunity to practice honesty. If an individual is stubborn and resistant, he must at some time or other have reacted to some situation which called forth a reaction called stubbornness, and so with any other behaviour pattern. This reaction hypothesis is one of the well-established hypotheses concerned with the development of human behaviour.

A fourth principle is that the practice or constant repetition of any behaviour reaction, or behaviour pattern, soon develops into what has been called habit; *i.e.*, a form of behaviour which tends to repeat itself when the appropriate stimulus or situation is presented. This principle is well recognized in the development of motor forms of behaviour, such as playing the piano, playing golf, running a machine, typewriting, etc. It is not so well recognized, but nevertheless just as important, in the development of the more complex ideational and emotional forms of behaviour. Such reactions as the development of an equation or the solution of an astronomical problem are, together with a certain native sagacity, largely the result of practice in previous forms of behaviour. So it is with emotional and attitudinal reactions, which develop as the result of practice or often because of the lack of it. An individual's concept of himself, his concept of his role in various forms of social behaviour, the feelings and attitudes he has toward himself and others result from the constant repetition of these same ways of thinking, feeling and acting at an earlier stage in life, usually in childhood or early adolescence. Through this constant repetition these forms of behaviour become habits; *i.e.*, they become fixed or preferred ways of acting and thus dominate, control and direct later activity. They constitute what is often described as the personality structure.

There are two or three corollaries to this fourth principle which must be mentioned. One of the most important of these may be stated as follows: Habits which are necessary and normal at one stage of life if persisted in become quite abnormal at a later stage. For example, it is normal and natural for a child to form habits of love and affection toward his mother. If, however, these same childhood habits of love and attachment persist without some modification into young manhood and adulthood, they become abnormal and bring the individual into conflict with the mores of his society.

A second corollary is that the lack of practice may be just as significant in the development of nonadaptive or abnormal behaviour as the actual practice of a behaviour pattern. For example, if a growing individual has never had an opportunity to react to situations which call forth honesty, kindness to his associates, a friendly manner, a tolerant attitude, a flexible nature, confidence and trust in people, a happy cheerful disposition and all the other behaviour patterns, which in our culture constitute what is described as a normal well-adjusted person, to that extent he will exhibit deviate or abnormal behaviour.

A third corollary of this fourth principle of adjustment, which must be briefly mentioned in order to understand the development of abnormal reactions, is that much of man's so-called unconscious behaviour (*i.e.*, behaviour of which he is unaware) is also subject to conditioning or habit formation. This was well demonstrated by the classical experimental work of Roderick Menzies. This experimenter was able to show that such delicate forms of response as the dilation and constriction of the blood vessels could be conditioned. By presenting first the original stimulus and associating with it some other stimulus such as a light, a bell, a spoken word or some physical contact, he was able to develop a substitute response in much the same manner as Pavlov, the Russian physiologist, was able to condition the flow of saliva in the dog.

The significance of this experiment for the understanding of the development of abnormal behaviour, such as is frequently seen in clinical cases, is quite obvious. The experiment suggests that in many abnormal subjects (*e.g.*, cases of hysteria and neurasthenia) the appearance of such symptoms as nausea, nervous indigestion and fainting spells may be attributed to conditioning; *i.e.*, the formation of habitual forms of response to new stimuli. In more technical language it means that the smooth or nonvoluntary muscles of the body can be conditioned in the same way as the striped or voluntary muscles.

It is necessary to present briefly a fifth principle in order to understand the motivation of either normal or deviate behaviour. This principle, first developed by R. S. Woodworth, and later enlarged upon by Gordon W. Allport, has been called the principle of functional autonomy. It may be stated simply as follows: by the continued repetition of an act certain neural mechanisms often called bonds or habits are established within the organism, which in turn become themselves motivating forces, or what Woodworth called drives. Thus, the organism becomes self-propulsive or autonomous and the postulation of such questionable concepts as instincts becomes unnecessary.

According to the theory of behaviour presented here, the following stages in the development of behaviour may be recognized:

1. The arousal of some physiological need or desire, such as hunger, thirst, etc., within the organism.
2. Resulting tension or conflict from the physiological activity.
3. Trial-and-error activity to resolve the tension.
4. Satisfactory socially accepted resolution of the tension.
5. The establishment of habits of response resulting from the successful and satisfying solution of the conflict.
6. These habits become drives or motivating forces and tend to repeat themselves.

Certain types of abnormal or deviate behaviour may develop at either stage 4 or 5. If, because of any one of a large number of possibilities which may arise in one's experience, no successful or satisfying solution results from the trial-and-error activity (*i.e.*, if conflict and frustration persist), the resulting behaviour will be "abnormal." Or it is possible that the behaviour growing out of the activity may be accepted in one social group or gang and not accepted by the dominant social group of which he is a part, in which case the behaviour likewise becomes abnormal or deviate.

Clinical Procedures.—We have dwelt at some length on the motivation and nature of behaviour reactions for two reasons: First, it gives an understanding of how many of the problems which come to the clinic develop and, second, it has a direct bearing on the methods of diagnosis and treatment. It is clear from the previous discussion that no adequate understanding of any behaviour pattern can be achieved without an investigation of at least four determinants of human experience: (1) The physical organism itself must be carefully examined; (2) the environmental forces which have acted upon the organism, and to which it has either consciously or unconsciously reacted must be thoroughly investigated (in other words, a detailed case history must be secured); (3) the individual's own feelings and attitudes toward the alleged problem, as well as his sense of values, must be studied; and (4) his abilities and aptitudes for growth and change must be appraised.

Finally, the results of these examinations, investigations and appraisals must be integrated and woven into a single picture of a growing, dynamic, living human being so that methods of treatment can be instituted. These various aspects of clinical procedure will be discussed in order.

The Physical Examination.—Every individual coming to a psychological clinic or being treated by the psychologist has, or should have had, a careful physical examination by a competent physician. The experienced psychologist holds to this rule rather rigidly even though 70% or 80% of the cases thus examined come back with physical findings negative or at most with minor physical defects. It is important in dealing with any clinical problem that the psychologist make sure either that he is not working with a behaviour disorder which is the result of some physical defect, or that if he is working with such a case, he do so in close co-operation with a medically trained person. A close working relationship with a physician is necessary for two reasons: It satisfies parents and clients who often are convinced that physical illness is responsible for the disorder, and it protects the psychologist from being accused of neglecting the physical factors.

The Case History.—In general the most important single instrument in the clinical examination is the case history. It is only through a case history that the psychologist can gain an understanding of the sequence of events which has produced the behaviour for which the individual comes or is referred to a clinic. It is only through a knowledge of the environmental forces, in their chronological sequence, which have acted upon the individual and to which he has reacted, that the psychologist can gain insight into the behaviour and consequently make a reliable diagnosis. These environmental field forces include not only those which constitute the cultural and community pattern, but also the subtle interactions in the immediate family group to which the individual has been exposed. Especially important are the forces to which the individual has reacted in the early years of his life, since these reactions form the habits of thinking, acting and feeling which become selective and contribute heavily to the determination of his later behaviour. In many clinical cases a detailed history alone is all that is needed to establish an adequate diagnosis and suggest methods of treatment.

The historical data required for the understanding of any given case will depend, to some extent at least, upon the problem involved. For example, it is of little value to secure a detailed report of the mental and physical welfare of the paternal and maternal grandparents or the aunts and uncles of a young child referred for nail-biting, thumb-sucking or enuresis. On the other hand, such information may be very necessary and pertinent if the child were referred because of mental retardation or some kind of seizure.

A number of detailed outlines for taking or recording the case history have been published. A useful one is contained in L. F. Shaffer's book, *The Psychology of Adjustment* ([under the editorship of Leonard Carmichael] Houghton Mifflin; N.Y., 1936). The following broad categories with a few of the details indicate some of the important lines of inquiry usually followed in these outlines:

Skeleton for Case History

I. Identifying data—name, age, sex, nationality, religion, etc.
II. Statement of problem
III. Congenital and physical factors determining behaviour
IV. Environmental forces or situations
  A. In the home:
    1. Father
    2. Mother
    3. Siblings
    4. Physical conditions in the home
    5. Method of control and supervision
  B. Community and cultural factors
  C. Educational and school experience
  D. Occupational experiences
  E. Recreational experiences
V. Reactions to the congenital, physiological and environmental forces
  A. Reactions in early childhood
  B. Reaction in later childhood and adolescence
VI. Sources of Information

Interview with the Client.—The interview is one of the clinician's most important instruments. It is on the interview that he must rely for much of the information necessary for a reliable diagnosis and it is through the interview that he must carry on much of his treatment. The art of interviewing is, therefore, carefully cultivated and refined by the experienced clinician.

There are so many circumstances which might alter the technique used in the interview that it is hazardous to attempt any generalization; nevertheless, there are a few rules which may be held inviolate. In clinical practice, most of these become so much a part of the clinician's technique and manner that he uses them unconsciously.

(1) The skilful clinician has a genuine interest in the welfare of his client. He has a warmth of feeling and understanding which is at once recognized as real and sincere and which induces an acceptance and confidence on the part of the subject.

(2) He is a good listener and is willing to permit the client full and free expression without injecting his own ideas, opinions or theories. This does not mean that he is a passive robot. The good listener is one who by his apparent passive manner still convinces the subject that he is genuinely interested in his problem.

(3) He is a keen observer of behaviour and is skilled in the art of interpreting expressive movements, verbal responses and changes of expression. He is able to recognize these as cues to the subject's ways of thinking, feeling and acting. While he is keen he is at the same time cautious. He recognizes that in the absence of objective data it is easy to make serious errors of interpretation.

(4) He has insight into the motivation of his own behaviour. He is aware of his limitations as well as his strengths and is able to compensate for them in some socially acceptable way.

Appraisal of Aptitudes and Abilities.—The appraisal of aptitudes and abilities by the use of psychological tests is such an important aspect of clinical methods that it was formerly frequently regarded as the only technique a clinical psychologist should use. Clinical psychologists later came to rely more and more on other techniques, such as those already described—the case history and the interview; nevertheless, psychological testing remained an important aspect of clinical methods.

Psychologists and other scientists through their constant and persistent research over a period of years have made available a large number of instruments for the appraisal of human behaviour. There are many manuals and textbooks describing these instruments, their use and interpretation. The reader is referred particularly to those by Edward B. Greene, Oscar K. Buros, R. Pintner, L. M. Terman and Maud A. Merrill, and David Wechsler.

Psychological tests are available for the study and analysis of a wide range of human problems, covering the age span from infancy to adulthood. In fact, these instruments had become so numerous by mid-20th century that mastery of the technique of administration and interpretation of all of them had become quite impossible. Usually the clinician has specialized either in the analysis of some particular type of problem, such as delinquency, marriage counselling, educational and vocational guidance, or in the problems of some particular age group, such as the preschool child, the adolescent or the problems of the aged.

In general, the psychological tests and inventories available for the appraisal of human behaviour can be classified into the following categories:

I. Tests of general intelligence (often described as tests of scholastic aptitude)
  A. Individual tests (those which can be given only to a single individual at one time)
    1. Verbal; *e.g.*, revised Binet tests
    2. Nonverbal, sometimes called performance tests
  B. Group tests (can be given to a group of individuals at the same time)
    1. For the primary grades
    2. For the intermediate grades
    3. For high school grades
    4. For college
II. Tests of school or academic achievement, sometimes called subject-matter tests. Tests are available for all subjects at all levels from the kindergarten to college
III. Vocational achievement tests and tests of special aptitudes. Tests are available for the appraisal of mechanical aptitude, clerical skill, speed of typing, motor agility, space perception, musical aptitude and appreciation, skill in the fundamentals of visual art, etc.
IV. Vocational interest inventories. These are used to determine the relative strength of an individual's interest in a profession, trade or occupation
V. Character and personality tests. These tests attempt to give a quantitative statement of the degree to which an individual deviates from the normal or average in some of the fundamental personality characteristics, such as neurotic tendencies, introversion-extroversion, sociability, ascendancy-submission, personal and social adjustment and other similar traits
VI. Rating and attitude scales. These are techniques for determining how a person feels about some controversial issue, such as communism, religion, birth control, etc., or are designed to get an appraisal of how a person rates among his friends and acquaintances on some particular trait, such as honesty or friendliness
VII. Tests of special disabilities, used to determine the degree of brain damage, degree of deterioration resulting from some disease, or some motor or sensory defect

The tests in some of these categories are much more reliable

and valid than those in the others. In general, the educational tests have the highest degree of predictability for the function for which they were constructed. Then follow the intelligence tests and the tests of special aptitudes and abilities. Character and personality tests have not proved to be so accurate in predicting the real situation.

Although in the clinical examination the most important purpose of the psychological test is the quantitative evaluation of some aspect of behaviour, nevertheless the psychologist also makes and records observations and impressions of the client during the testing session. Often these observations contribute more to the understanding of his behaviour than does the quantitative rating. In one sense, the testing situation may be regarded as a controlled situation in which the individual's behaviour is being observed.

Methods of Treatment.—*Some Theoretical Considerations.*—The term "treatment" as it is used in clinical psychology is in many respects an unfortunate one because it fails to reveal to the reader the nature of the procedure involved. In fact the term actually conceals the essential characteristics of the process in that it tends to imply that the treatment is something which can be imposed from without. "Therapy" has similar objections. These terms, like "clinical," were borrowed from medicine and have, unfortunately, brought with them some of the same meaning they had in that discipline.

The term "re-education," or even "education," might more nearly describe the nature of the process than either "treatment" or "psychotherapy." The essential nature of psychological treatment is the same as that involved in any other educative process. The chief difference between the education by the clinic, on one hand, and the education of the home, the community or the school, on the other, is that in the former it is necessary to devise techniques and schemes to break down old habits as well as to establish new ones, while in the latter the teacher, parent or guardian is concerned for the most part in building up new ones only. Even this distinction does not always hold. Often the good parent or the good teacher is a good clinician, employing with skill and accuracy all the essential methods of treatment employed by the psychologist. Frequently, it is the chief task of a parent or teacher to re-educate as well as educate.

Treatment involves a change in behaviour. The task of the clinician is so to arrange events and situations as to bring about this change. If the child has been brought to the clinic because he has been truanting from home and school, then the task of the clinician is to change this behaviour pattern. If a client comes because he has a number of unexplained fears and anxieties, the task of the clinician is to help him get rid of them. Treatment of any problem involves either the acquisition of a new behaviour pattern, or discarding an old one, or both.

The method of developing new patterns of behaviour is a problem to which psychologists have given a great deal of attention. On one point there seems to be general agreement; namely, that behaviour can be developed only through some kind of a reaction to a situation or a stimulus. This has already been referred to as the reaction hypothesis. It is stated by Arthur I. Gates in *Psychology for Students of Education* (Macmillan) as follows: "All forms of human behavior, whether muscular activities, such as those of grasping, striking, or speaking; glandular activities such as the secretion of tears, saliva or gastric juice; or mental activities, such as perceiving, imaging, remembering, thinking or reasoning are reactions to definite stimulation."

The hypothesis has two implications for so-called treatment: (1) If a behaviour pattern is to be changed, some stimulus or situation must be constructed to motivate the change; and (2) the subject must be given some opportunity to practise or exercise the behaviour in the making. These are essential elements in the acquisition of any behaviour pattern. If this hypothesis is accepted, then no treatment can be effective without having inherent in it these two factors.

Many techniques and methods have been used by psychiatrists, psychologists, teachers, ministers and priests in their attempts to change behaviour patterns, and practically all methods from Coué̇ism to psychoanalysis have some claim to success, in terms of the individual case. The lame have walked and the blind have seen. Little carefully controlled experimental work on the relative value of different methods of therapy, however, has been reported. Thoroughgoing and systematic accounts of various treatment techniques have been reported by Carl R. Rogers, Leo Kanner and J. McV. Hunt.

In general, these treatment processes may be classified into two large categories: those involving actual change of the environmental situation, and those involving change of attitude toward the environment on the part of the client. The difference between these two is more apparent than real. As far as the psychological process which goes on within the individual, they amount to the same thing; *i.e.*, they modify the stimuli which play upon the individual and thus modify his behaviour. These two methods will be discussed in order.

Modifying the Environmental Forces.—Psychologists have used many techniques to modify the environmental forces which play upon the individual: (1) If the situation demands it the client may be physically removed from one situation and placed in another; *e.g.*, moved from his home and placed in a foster home or institution. Thus, he is forced to react to a completely new set of environmental situations with the expectation that by so doing the desired changes in behaviour will result. (2) The field forces which act upon the individual and to which he reacts may be changed by changing the attitude of the parents, siblings, teachers and others toward him, and thus a change in behaviour may result. (3) A change in the environmental forces may be brought about by providing more adequate recreation facilities and play activity. The client may be provided with membership in some club or given a library card, or sent to a camp, or, if the individual is older, he may be advised to take a vacation.

The methods of modifying the field forces can be almost indefinitely multiplied, depending upon the results of the diagnostic procedures. The three methods mentioned are those commonly used in clinical practice. The value of this type of treatment will depend upon the skill and ingenuity of the therapist in providing situations which the client accepts, for it is only as he accepts them that they will have any re-educational value.

Modifying the Client's Attitude.—In many instances the treatment cannot be carried out through the modification of the environmental forces alone. Often it is necessary to effect a change in the individual's attitudes toward himself, toward his associates and, perhaps, toward society in general. Frequently, a complete reorientation of his concept of himself or his concept of the relationship between himself and his associates or the relationship between himself and his immediate family is necessary. During the process of his development, he has accumulated a number of faulty habits of thinking and feeling and acting, and a complete modification of his philosophy of life is the only method by which his behaviour can be altered.

This modification of behaviour is always difficult and prolonged and often it is impossible. If the client has developed fixed ways of feeling and acting, then he is likely to assume that same role toward the therapist and resent any intrusion into his private affairs. Or he may attempt to prove to the therapist that his way of thinking and feeling is the only correct one and everyone else should accept it.

Many techniques have been devised and developed in the attempt to modify the individual's ways of thinking, feeling and acting. One of the best known is psychoanalysis (*q.v.*). This is an elaborate theoretical psychological system, a discussion of which does not belong here. As a technique of therapy, it involves a detailed report to the analyst (and under his direction) of the past experiences of the individual and especially the experiences of early childhood. He is expected to report his relation to the mother, the father, the siblings, his associates and the influence of these upon his own development. This report, which may take several months, is interpreted to the client in accordance with psychoanalytic theory.

The assumption in this method of therapy is that once an individual has an intellectual understanding of all the forces that

make him act the way he does he will change his behaviour to more socially acceptable patterns.

Another technique for modifying human behaviour is that developed by Carl Rogers. This has been called the nondirective or client-centred method of counselling and psychotherapy. The chief difference between this and the older psychoanalytic approaches from which it is partially derived is that the focus of attention in the therapeutic relationship is on the development and integration of the individual into a more consistent personality during the counselling process and not on an analysis of his problems through a probing into his past history. It is assumed in this procedure that the client is capable of effecting this integration if he is given an opportunity to relate and consider his experience as well as his own thinking and feelings.

Clinical Methods in Industry.—*The Selection of Personnel.*—The clinical approach to understanding of human motivation and personality structure has been increasingly used in the selection of personnel in industry, especially in the selection of top management. At the supervisory level the older approach (namely, that of making selections on the basis of a battery of tests) proved relatively sterile. It was assumed that the more elaborate and more time-consuming method of the clinical approach would prove more successful. This assumption had not, however, been experimentally demonstrated by the mid-20th century.

The methods used in the clinical approach in industry are essentially the same as those in use in counselling centres, guidance laboratories and clinics already described. In industry, however, the orientation and the problems to be solved are quite different. The clinician is not, as a rule, so much concerned with the problems of the individual as such as he is with predicting probable success in a given position. The methods are usually used in the selection of men for supervisory positions. Some of the questions the clinician must be prepared to answer are such as these:

Does the man think accurately and comprehensively?
Is he able to look ahead and make long-range plans?
Is he able to take orders without offense and give them with composure?
Can he lead others to accept his ideas without force or regimentation?
Can he give criticism frankly, honestly and objectively?

In selecting a man for a supervisory position, it is necessary to be able to answer these and many other questions dealing with the intellectual, emotional and social characteristics of the client before making any prediction about the man's success in a given position.

The information which enables the clinician to attempt answers to these questions and make a final recommendation to management is not secured from objective measurements alone. The amount of error in prediction is considerably reduced by following the usual clinical procedure of integrating the test findings with information gathered from a personal history and an interview with the candidate.

The Developmental Interview and Upgrading.—The therapeutic procedure, or developmental interview as it is called in some organizations, follows the same line as that used in the usual clinical situation, except that as a rule the ultimate purpose of the interview is to increase the man's efficiency in a given position and prepare him for upgrading rather than the development of his personality as an individual, although the two possible objectives are by no means incompatible. Frequently, greater efficiency on the job is best achieved and preparation for upgrading is best accomplished by conducting the developmental interview with the purpose of helping the client meet and solve some of his own personal problems.

EDUCATIONAL PSYCHOLOGY

Educational psychology is that branch of psychology which deals with applications of the subject to the work of the schools or other educational agencies. In large part it utilizes material in related branches such as child development and mental measurement, but includes much distinctive matter of its own, as on the psychology of reading and arithmetic, and the social psychology of classroom relationships.

Co-ordination of Development and Education.—Educational psychology may be thought of as concerned, first of all, with proper co-ordination of educational programs with processes of psychological development. At what age should a child start to school? There is much evidence that many children can profitably begin nursery school as young as two or three. There they learn to get along with other children, have more resources for healthy play than most homes afford and are under the supervision of young women especially trained in understanding of young children and their problems. When should the usual more formal schooling begin? The average child of four is quite evidently too immature to begin a subject such as reading; continuing close inspection of the printed page is a strain on childish eyes (which tend to be farsighted), vocabulary is too limited and capacity to learn visual symbols is as yet inadequate. There is much to suggest that the usual age of six is the best age to begin reading; but there is also evidence that the less able children may well delay reading, meanwhile developing more simple skills and direct learning through field trips and activities in the school. Is 16 too young to enter college, or 20 older than desirable? When should young men and women finish their full-time schooling and begin their life careers? Do adults present special problems as regards interests, ways of learning or personality of which adult education should take account? All these are important questions which became better understood as a result of research in the total field of educational psychology.

Investigations of child development bear not only on desirable ages for beginning or concluding various segments of the educational program, but also on desirable features in the program at different ages. Thus, boys' reading interests are different at 12 and 17—centred on adventure and mechanics at the first age, but beginning to show romantic leanings at the latter. This romantic interest is reached earlier by girls, as would be expected because of their earlier physical maturing. A type of poetry which is not understood at one age and strongly disliked at another may be a delight at yet a third stage of development. Only if the reading matter which a school (or library or home) offers young people at each age is suitable to their stages of development will they profit from that material or enjoy it.

Since the modern school is concerned not simply with the learning of formal school subjects but more broadly with total development, evidence regarding the social psychology of childhood and adolescence is also relevant for educational planning. Numerous investigations of childhood companionships have shown stages of growth from the superficial associations of young children to gang groups all of the same sex in later childhood, and the "crowd" of both sexes in adolescence. School activities appropriate to each age can do much to foster healthy social growth.

Application of Research on Learning to Education.—Gradually, the numerous investigations of the learning process made clearer the problems of teaching and helping children to progress more readily. In fact, evidence accumulated to show that (contrary to common belief) children in good modern schools were progressing more rapidly and learning more effectively than pupils of 50 or 100 years before. Thus, it became known that reading is a process of recognizing whole words or phrases much as one recognizes a face, rather than knowing a word as composed of certain letters. Children in modern schools often start to read by learning words rather than the alphabet. Likewise,

children learn most adequately when the learning is related to projects or undertakings which are part of their everyday out-of-school life and closely related to childhood concerns. Thus, one investigation showed that when a class read about what could be done to deal with a local epidemic that caused the illness of some of its members, made measurements and figured costs for screening to prevent fly-borne transmission of the disease and wrote reports about the epidemic which they proudly presented in neighbourhood meetings, they not only learned more about health problems but also read more widely, became more accurate in arithmetic calculations and wrote more carefully than pupils in other classes who had simply had the conventional work in hygiene, reading, arithmetic and composition.

Clever but simple experiments have indicated that praise is more effective than criticism in stimulating learning, that effort falters when no progress seems to be made, that goals which are vague or so difficult as to seem unlikely of accomplishment make the learner fumble and seek other interests. Other experiments have shown that much if not most of the more miscellaneous information learned in school (facts of history or vocabulary of a foreign language) are soon forgotten, but that information and skills which are used, and larger understandings, appreciations and attitudes, are retained much longer.

Experimentation on "transfer of training," or the extent to which a pupil's study of one subject carries over to affect his work on another subject or in another field, has important bearings on both teaching and the curriculum. Thus, study of Latin appears not to "train the mind" in the sense that from long wrestling with Latin syntax one develops stronger "mental muscles" and in consequence can deal more effectively with history or bookkeeping or business problems. Rather, training is relatively specific. A pupil who has studied Latin may, a little more readily than one who has not, infer the meaning of unfamiliar English words of Latin derivation; but he may not do better with English terms derived from Arabic or German. However, it is possible to "train for transfer." Thus, by pointing out Latin words having English derivatives, and developing skill in analyzing English words for their roots and in use of the dictionary, a Latin teacher may increase the help his subject gives in English word study. And there is evidence that by emphasis on methods of wide applicability, a skilful teacher of almost any subject can make it of wider usefulness. Journalism or bookkeeping, as well as Latin or geometry, may thus increase English vocabulary or habits of accuracy.

Educational psychology is also concerned with tests and measurements. Numerous tests of general ability are available to aid in determining whether a given child is bright or dull for his age. Tests in the school subjects show how he stands in reading or arithmetic or algebra or foreign language, and diagnostic tests analyze a pupil's difficulties. Other tests deal also with his attitudes and beliefs, his tendency to form hasty judgments or react excessively to what is seen or heard, his honesty or cooperativeness. "Sociometric" tests show his social status in a group. These various measurements guide teachers in their work. They may also help pupils by showing what they are to do, where they stand, what their difficulties are and how they are progressing.

Individual Differences; the Individual.—Educational psychology also concerns itself with individual differences in rate and nature of development and in rate and method of learning. Differences in physical development are great, and may present psychological problems. Thus, in a given group of 15-year-old boys, one may weigh 150 lb. but another only 80 lb. One may still be a prepubertal boy but another may have reached puberty three years before and show both the maturity of physique and the interest in the other sex natural to a high school senior. These differences present problems in planning sports so that some boys will not be grossly outclassed physically by others. They should be also taken into account in planning social activities; a boy who has not yet reached puberty will be out of place in a group of youngsters for whom companionship with girls is the new-found consuming social interest.

Differences in mental traits are also great. In a given school a few 10-year-old children may be no brighter than the average 6-year-old, whereas an occasional superior child may be as bright as average youngsters of 14. Some fifth-grade children may read four times as fast as others; some complete a lesson in one-fourth the time others need. How best to advance pupils, group them or make work in each class adjustable to take account of such differences is a major education problem.

Educational psychology is concerned not only with such differences in various traits, but also with their correlations—the extent, for instance, to which pupils who learn quickly remember well. In general, these correlations are positive; thus, the common belief that the rapid learner forgets more quickly is not true. In general, bright children also tend to develop more rapidly and at a given age to be larger and socially more mature than less intelligent youngsters; popular concepts of the intellectually superior child as physically puny and socially maladjusted are incorrect. It is therefore feasible for many bright children to progress through school at a faster than average pace.

The individual is not simply a collection of traits, however. Modern research has emphasized the fact that he is an integrated, dynamic personality. His failure in algebra may be because of mediocre intelligence. But it may be, instead, a result of poor grade school teaching of arithmetic, and remediable upon adequate diagnosis. It may be a by-product of acute emotional distress caused by lack of status with schoolmates, or conflict in the home. Educational psychology seeks especially to penetrate through the more general facts about human development and learning, and reach the major underlying influences which make each individual what he is. Understanding of these is most important if any educational program is to attain maximal effectiveness.

LEGAL PSYCHOLOGY

Psychology deals with the prediction and control of behaviour, and the law is concerned with the regulation of conduct. These two objectives obviously have much in common, and the field of legal psychology explores this common ground with a view to reducing errors in testimony and preventing crime through better understanding of its causation.

Psychological Sources of Error in Testimony.—Even a straightforward witness may make mistakes. Some of these may be a result of failure to perceive the original event correctly. Typical instances would be: nearsightedness or colour blindness; adaptation of the eye, as when going into a dimly lighted room from the sunlight outside and consequently failing to observe an individual or an obstacle; judgment of the length of a time interval as influenced by what else the witness was doing in that interval. Certain types of stimuli such as loud sounds, unusual events or large or moving objects secure a higher degree of attention and hence will be reported more accurately.

Memory.—Further error may be the result of lapses of memory in the period between the event and the testimony. Something observed only once would be less readily recalled than something noted repeatedly. Emotions are disrupting experiences and persons involved emotionally in an accident or a fight would be more apt to forget details than would a dispassionate bystander. Memory is adversely affected by disturbances after the observation. A person who is knocked unconscious could not be expected to give a good account of events right up to the moment when he was hit. Recognition is a special phase of memory and mistakes are common when the new object contains some elements like those of the earlier one and those common elements suffice to give an impression of familiarity. In identifying suspects, false recognition may be minimized by having the witness select the

suspect from several possibilities rather than responding categorically to a single suspect.

Suggestion.—When securing testimony by questioning a witness, there is a danger of obtaining incorrect answers through the medium of suggestion; that is, planting an idea which the witness accepts. The examiner may give suggestions unintentionally in accordance with his own theory of what happened. The form of the question also has some bearing on its suggestiveness. Leading questions may be ruled out in the trial, but nevertheless, if they are asked at all, the suggestion may influence the witness and also the jury.

Some of the foregoing sources of error in testimony have been recognized by the courts and precedents have been established. Others are obvious to the psychologist but have not appeared as yet in actual court procedure.

Psychological Techniques for Crime Detection.—The term "lie detector" is unfortunate, because it implies a certainty which is unwarranted. There is no more a lie detector than there is an appendicitis detector or a tuberculosis detector. A physician notes symptoms such as body temperature, pulse, breathing rate and blood count and on the basis of these symptoms makes a diagnosis. By the same token the psychologist notes certain aspects of breathing, blood pressure and electrical resistance of the skin while a suspect is being questioned, and, from various subtle symptoms in the graphic record, diagnoses guilt and falsehood. Several techniques are employed simultaneously, but in the following discussion they will be treated separately.

Blood Pressure.—Probably the most successful indicator of deception is the systolic blood pressure. A continuous record which is a function of the systolic pressure may be obtained by a pneumatic step-down device connecting a rubber cuff placed around the upper arm with a metal bellows and recording pen writing on a moving paper tape. The graphic record shows a little wave for each pulse beat, and if the blood pressure increases, the crests of these waves reach a different level. The record is taken continuously during oral examination of the suspect. This examination must include control questions on which the suspect will undoubtedly tell the truth. It is also well to phrase the questions so as to elicit "yes" or "no" answers because the muscular work of talking introduces irregularities into the record which complicate the interpretation. After each question there is usually a slight rise in blood pressure for a few seconds. If there is an emotional disturbance from telling a lie, this rise in blood pressure is apt to be a little greater and a little longer. Diagnosis is based on comparison of these changes on crucial questions with those on control questions.

Breathing.—A graphic record of breathing may be obtained by placing about the chest a device which operates pneumatically and causes a pen to trace on the moving paper tape a wavy line corresponding to the inspiration and expiration. The expert generally interprets this record qualitatively in terms of changes in rate or depth. A more detailed analysis may be made by computing the ratio between inspiration and expiration time for each breath. If the ratio after the suspect's answer is greater than the ratio before his answer, there is some presumption that the answer is false and vice versa.

Electrodermal Response.—Changes in the electrical resistance of the skin are caused by emotional conditions. This electrodermal response is recorded by placing two electrodes on the skin and applying a few volts. Changes in potential between the electrodes can be amplified sufficiently to operate a galvanometer which in turn may record on the moving tape. The extent of the deflection and its rate of change may be diagnostic. The electrodermal response is not so successful as the blood pressure in actual detection work. It appears to be more specific for the type of emotion originating in some sensory disturbance like a startle, whereas the blood pressure responds more to emotions resulting from ideas, such as those involved in deception.

Association Reaction Technique.—In the oldest of the psychological techniques for crime detection, the examiner presents stimulus words one at a time, the suspect responds with the first word which occurs to him and the reaction time required for this response is recorded by an electrical timing device. Some of the stimulus words are crucial, in the sense that they would remind the actual offender of the crime but would have no such significance for the innocent suspect. The other words are normal or control words. The guilty suspect may betray himself by responding to the crucial stimulus words in such a way as to reveal familiarity with the crime or if he is able to suppress such incriminating responses, the reaction times may be longer. A supplementary technique involves a pneumatic reaction key which the suspect presses at the same time he gives his oral response. Actually the apparatus records the position of his finger continuously on a moving tape and a premature or unusual manual response will be noted.

Difficulties with Crime Detection Techniques.—It is sometimes asserted that techniques like the foregoing would convict the innocent. An excitable person would undoubtedly show considerable disturbance under examination even though innocent. The point is, however, that the individual is always used as his own control. The innocent, excitable suspect might show disturbances on the control questions but would show little more on the crucial questions. An unexcitable, guilty suspect on the other hand would show rather slight disturbances on the control questions but appreciably more on the crucial because of the additional increment of emotion resulting from deception.

Usefulness of the Technique.—From the early 1920s techniques of this sort were employed in examining criminal suspects. Their greatest usefulness lies in preliminary examination with a view to getting further clues, eliminating innocent suspects and, in general, narrowing down the problem for the police. The scientist does not use the device to frighten the suspect into a confession which may be untrue and actually the result of suggestion. Neither does he compel anyone to undergo this type of examination. However, most suspects voluntarily submit, because refusal would appear suspicious.

Legal Status.—Techniques of this sort up to the mid-20th century had not been admitted to any extent as legal evidence. There had been a few cases, however, in which defense and prosecution agreed in advance to have an examination conducted by these methods and to waive any question of admissibility of the evidence. In the hands of properly trained persons these psychological techniques can be of considerable help in the field of criminal interrogation. In the wrong hands they can be grossly and unscientifically misused.

Psychological Factors in Causation of Crime.—Some criminal behaviour can be traced directly to mental disorder or disease in the offender. A patient with a delusion that someone is trying to kill him may take matters into his own hands and attack someone whom he "recognizes" as the persecutor. Delusions of grandeur may lead a person to write checks on an imaginary bank account. General instability may result in violence or wanton destruction of property. One type of epileptic may commit murder during a seizure and have complete amnesia for the act. Sadism, a sex perversion centring around cruelty, may involve the most gruesome type of murder. Borderline disorders as contrasted with major insanities also contribute to delinquency. When a person becomes frustrated by some combination of circumstances, he may not meet his problem in normal fashion but get emotional release through some questionable behaviour. Shoplifting sometimes is an outlet for frustration and the desire to assert oneself.

Mentally Defective Delinquent.—The mentally defective or feeble-minded person has characteristics which, in a way, predispose him to crime: he is unable to compete satisfactorily in a vocational situation, with resulting financial difficulty; he lacks foresight and will, for instance, commit a murder with no consideration of an alibi; he tends to act on impulse and is unduly suggestible. Numerous studies have been made of groups of delinquents to determine what proportion are feeble-minded. The results depend greatly on how the sample is selected, but in general reveal a sufficiently large proportion of defectives among the delinquents to constitute a real social problem. The proportion is usually higher with juvenile delinquents than with adults,

and is likewise considerably higher with repeaters than with first offenders.

The casual criminal has nothing in his history and no observable psychological characteristics which would indicate that he is going to commit a crime. He simply gets into a situation that is too much for him. The main problem here is to forestall a second offense.

Suggestion as a Cause of Crime.—A frequent source of suggestion, that is, getting the idea of criminal behaviour, is found in a youngster's associates. If his group is indulging in petty delinquencies, it is natural for him to do likewise and go from bad to worse. Another source of unfortunate suggestion may be the home, especially if it involves undue laxity of behaviour. Newspaper publicity is another source; crime news is featured extensively and in detail, so that the reader may find just how the jewellery store window was cracked. He may get the impression that almost everyone does this sort of thing. There is often insufficient emphasis on conviction and punishment. The same principles may operate to a lesser degree in books and periodicals which feature crime. Motion pictures contribute information as to criminal *modus operandi*. They may be alleged to teach that crime does not pay but, all too frequently, the audience spends several hours observing a criminal who is clever, well-dressed and glamorous and has a good time while it lasts, and the retribution that finally overtakes him occupies only a few seconds and fails to leave a lasting impression. Television operates similarly.

Drugs.—The drug addict has a profound motivation to get more of the drug and will stop short of nothing. This may lead to violation of the drug law or actual violence for the purpose of obtaining money to buy more narcotics. Alcohol contributes somewhat to crime. Contrary to popular belief, it is a depressant rather than a stimulant as far as actual mental and motor performance is concerned. The feeling of superiority is somewhat illusory but there is a general lowering of inhibitions.

Psychological Factors in Crime Prevention.—*Predelinquency.*—The crime usually is not the first symptom of mental disorder, but the individual manifests delusions or withdrawal tendencies long before he gets into trouble. Relatives or school personnel should be aware of the significance of these symptoms and get expert help in diagnosis. Police have sometimes located these predelinquents by investigating more carefully the chronic complainant who may actually be thus manifesting his instability. It is much the same story with the early detection of mental defectives who may later develop delinquent tendencies. Intelligence tests administered in the school system may help on this point.

Eugenics.—Mental defect and mental disorder have a distinct hereditary element. There are numerous instances of families with a high incidence of feeble-mindedness in successive generations. With mental disorder the situation is complicated by the fact that both predisposing and exciting causes are involved. One may have the hereditary predisposition, but does not become insane unless he gets into a situation which touches it off. Nevertheless, numerous studies reveal an unduly high proportion of mental disorder among relatives of disordered persons.

If mental defect and mental disorder account for a fair amount of delinquency and these characteristics are to quite an extent hereditary, an obvious crime prevention procedure would be to stop breeding feeble-minded and insane.

Control of Sources of Suggestion.—Another contribution to crime prevention would be the control of sources of suggestion mentioned in the preceding section. Suggestion from associates could be minimized by giving the youngsters more salutary things to do in their spare time through provision of recreational facilities. Some toning down of crime news might be feasible with more emphasis on retribution. The motion picture scenario might eliminate some of the criminal detail and the glamour and put more emphasis on the penalty.

Drugs.—Enforcement of laws regarding narcotics is difficult because of the small size of the material. An appreciable amount can be transmitted under a postage stamp. A long sentence for addicts sometimes makes it possible for them to become weaned in the process. Education as to the danger may help forestall youngsters from trying a drug out of curiosity and thus getting the habit.

Punishment.—One function of punishment is to deter people from committing crime. If the deterrent effect is analyzed psychologically, it appears to have two aspects—the severity of the penalty and the certainty of its enforcement. Some people are deterred primarily by one aspect, and some by the other. If punishment is to be an effective deterrent for everyone it is necessary to stiffen up both aspects—severe penalties and rigorous enforcement.

Another function of punishment is reformation of the criminal. While he is incarcerated, it may be possible to correct his underlying philosophy, to teach him a vocation that he can follow when he gets out, and to help him plan his life so that he can keep out of trouble and find interesting and profitable things to do. A little counselling at this point supplemented by some follow-up after his exit by a sympathetic worker may go a long way in keeping him straight. Many of the casual criminals mentioned above need not be permanently delinquent.

Education.—The educational system has contributions to make to crime prevention. For one thing it keeps the youngsters out of mischief while they are in school. Vocational education is another aspect. There is much controversy as to the comparative importance of vocational and cultural education, but at any rate vocational adjustment does have an obvious relation to getting along satisfactorily from an economic standpoint and perhaps keeping out of trouble. Vocational guidance, which often is part of the school program, can contribute in similar fashion. If the individual is directed into a field in which he has a good chance of vocational success, then his whole life adjustment will be better and the probability of his getting into questionable activities will be thereby reduced.

Trade-Marks and Trade Names.—Trade-marks and trade names are designed to protect the manufacturer who has invested capital in the promotion of his product and to protect the consumer who wishes to purchase more of a product which he has found satisfactory. Sometimes, however, a trade name or mark that is similar to the original deceives some purchasers. The manufacturer of the original product may take legal action against the alleged infringement. A basic consideration in such a case is the actual extent of confusion between the two names or marks; *i.e.*, the probability that the consumer will actually purchase the wrong brand. This is essentially a psychological problem in the field of recognition.

It is possible to determine experimentally the degree of confusion between two similar trade-marks or names. A list of trade names is presented to a considerable number of persons at a standard rate and these observers merely attempt to remember the names. Then a second list is presented more slowly and they are required to indicate which of the words in the second list were actually in the first. Some of the names in the second list are identical with those in the first, and some are entirely new. The name used by the plaintiff is included in the first list and the name used by the defendant in the second. It is possible to determine what proportion of the observers erroneously state that the name of the defendant actually was in the first list. This per cent of confusion must be evaluated relative to the amount of confusion on the words that are duplicates or actually new, as this latter indicates the general difficulty of the experimental conditions. Investigations along these lines have served as the basis of expert testimony by psychologists. (H. E. Bu.)

PHYSIOLOGICAL PSYCHOLOGY

Physiological psychology is the science which deals with the relations of behaviour and of mental processes to the physiological activities of the various organs of the body. Development of the science has been complicated by the apparent distinctness of the two problems implied in this definition. Behaviour, even speech and other modes of transmitting ideas, is made up of muscular movements and so can be dealt with as a part of the

activity of the body. The relation of mental states to bodily activity, on the other hand, has seemed to many students to constitute a problem of an entirely different order. The mind-body problem has been a major topic of metaphysical speculation and has influenced the direction of much of the research in psychology.

Some of the effects of injuries to the brain were known to the physicians of antiquity. Galen taught that the brain is the seat of the intellect, as had members of the Alexandrian school before him, but the belief that vital processes are maintained by circulation of body fluids, or humours, led to the ascription of mental functions to the ventricles of the brain and to other organs, especially the heart, liver and spleen—a belief still recalled by such terms as sanguine, melancholy and phlegmatic, descriptive of temperamental traits. Progress in understanding behaviour was impossible until the rapid development of anatomy during the 15th and 16th centuries laid a foundation for physiological studies.

The first attempt to formulate a systematic physiological account of behaviour was that of René Descartes (1649), who ascribed the movements of animals to the mechanical action of the nerves but reserved to man an immaterial, rational soul, intervening in the actions of the brain. The next two centuries witnessed controversies between those who, like Giovanni Borelli (1680) and J. O. de Lamettrie (1745), sought a mechanical explanation of vital phenomena and the advocates of mystical, vitalistic theories such as that of Georg Ernst Stahl (1707). The observations of Jan Swammerdam (1674) on muscular contraction and of Thomas Willis (1681) on the effects of destruction of different parts of the brain initiated the experimental study of the functions of the nervous system. Understanding of reflex action and of special functions of the different parts of the brain was extended by Johann Unzer (1771) and George Prochaska (1784), who compiled and interpreted the knowledge of their times. The distinction by Charles Bell (1811) between sensory and motor nerves and the extensive experiments by Pierre Flourens (1824) mark the beginning of the modern period of research on the nervous system.

Evidence for dissociation of mental functions by brain injuries, derived from the demonstration of speech defects following damage to the frontal region by Paul Broca (1861), and of paralysis of voluntary movements following destruction of the motor cortex by G. Fritsch and E. Hitzig (1870), went far to destroy the conception of the unitary character of mind and to establish the theory of the dependence of behaviour upon nervous activity. Following these investigations, the study of the nervous system expanded with amazing rapidity. In the next 50 years more than 3,000 articles dealing with behavioural disturbances following brain injuries in man alone were published. In 1874 Wilhelm Wundt published the first book dealing specifically with physiological psychology, and established a laboratory devoted to the subject, but the important contributions continued to come chiefly from the physiological laboratories and the clinics. Charles S. Sherrington demonstrated the intricate relations of reinforcement and inhibition among reflexes, and the Russian physiologists, Ivan Pavlov and W. von Bechterev, extended the conception of the reflex to include learned actions and cerebral functions. Finally, the invention of methods of electrical amplification made it possible to trace nerve impulses within the central nervous system and to demonstrate beyond question the uninterrupted physical continuity of nervous activity from the stimulation of sense organ to the production of muscular movement.

The conception of the relation of mental processes to the body changed steadily under the influence of the physiological studies. Belief in the interaction of mind and body as distinct modes of being, expressed by Descartes, was weakened by the attacks of the 18th-century materialists, by evidence for the physical continuity of reflex action and for the similarity of nervous structure and function in animals and man. Even in 1870, Fritsch and Hitzig described the motor cortex as the point of entry of "single psychic functions into material," and L. Hermann could deny the validity of their observations and the possibility of separate localization of functions in the cerebral cortex because the mind is one and indivisible. The rapid acceptance of the physiological determination of behaviour, however, soon left mind without apparent function, an epiphenomenon, as Thomas Huxley termed it. For a time the theory of psychophysical parallelism, first formulated by Gottfried Leibnitz (1795), was widely held. This assumed that mind and body represent two independent causal sequences, timed to run concurrently, but without any mutual influence.

Psychological analysis was, however, rapidly doing away with the supposedly unique character of mind. Wilhelm Wundt and his followers reduced experience to sequences of sensation and feeling, and Oswald Külpe demonstrated that the effective activities of thought, the organizing of ideas or acts, is entirely unconscious and can only be inferred as a nonmental activity. The new realists attempted to analyze further the distinguishing characters of mental processes and were able to define them only as relations between terms having in themselves no attributes of mind. The outcome of these psychological studies was the conclusion that mental states and activity are characterized solely by their organization, and that this organization may be identical with that of the physiological activities of the brain. This identity hypothesis in one form or another had become dominant in psychology by the mid-20th century. It was still only a working hypothesis but it was being continually supported as knowledge of neurophysiology revealed the basis of relationships which have been thought to be uniquely mental. The transfer of problems to physiology from the realm of psychics is illustrated by the history of psychophysics, which began as a study of the relation between intensity of stimulus and intensity of sensation. These studies revealed a constant ratio, expressed roughly by the statement that the intensity of sensation varies with the logarithm of the intensity of the stimulus. Gustav Fechner, who developed the measurements, believed that this law expressed a quantitative relation between neural activity and mind, and was thus a truly psychophysical measure. The law, however, did not hold for very weak or very strong stimuli. Work in neurophysiology showed that the measurements actually describe the relation between the intensity of stimulation of a sense organ and the number of nerve impulses which it discharges, and that the discrepancies at low and high frequencies are caused by the limited number and refractory periods of the nerve fibres involved. Many such instances justify the expectation that the organization which seems characteristic of mental processes will be found to be that of nervous activity.

Physiological psychology came to deal primarily with the physiology of the nervous system. There were, however, many instances of the influence of physiological processes upon behaviour which could not at mid-20th century be described in terms of nervous activity. Among these were the effects on behaviour of oxygen deficiency, of fatigue, of the concentration of internal secretions, of vitamin deficiencies, of toxic drugs, to cite only a few examples. Their effects on mental activity and behaviour may be studied and the results may find practical application before their mode of action through the nervous system is known. Physiological psychology had come to be largely concerned with the action of such agents, whose effects were known but by no means completely understood. It is a compilation of material from many sources—biochemistry, anatomy, physiology, clinical neurology, psychology and psychiatry—selecting relevant facts from each and orienting them in reference to the problems of behaviour. There is space here only to enumerate topics which have been most intensively investigated and to indicate the nature of the results.

Neurophysiology.—The action of sense organs, the transmission of nerve impulses to the central nervous system, their integration there and the final excitation of muscles are described in articles on the special senses and on the nervous system. These facts are basic for physiological psychology but need not be reviewed here.

Heredity of Mental Traits.—The difficulty of measuring individual differences and the readiness with which they are

modified by environment has limited the study of their inheritance to the more extreme and stable variations. In experiments with animals, both temperamental traits and learning ability have been shown to be inherited. In man, emotional traits, certain types of mental deficiency and the tendency to some nervous and mental diseases are clearly hereditary. Studies of identical twins indicate that the level of intelligence may also be genetically determined. With few exceptions, such as amaurotic family idiocy and sex-linked colour blindness, such traits show blending inheritance and multiple gene determination.

Physical Types and Personality.—The possibility of association of mental traits with external characters of the body has claimed interest from ancient times and many systems of character reading from the shape of the face, head or body have been advocated. The most widely known of these is Franz Joseph Gall's phrenology, which attempted to deduce the functions of the brain from the shape of the skull. Ernst Kretschmer's claims for behavioural differences between pyknic, asthenic and athletic body types (the fat, the lean and the muscular) acquired the largest scientific following. Careful investigations of the claims of these various systems failed to reveal any consistent relation between somatic characters and temperament or capacity. Only in certain pathological conditions, such as microcephalic idiocy and the glandular dysfunctions of cretinism and exophthalmic goitre, are such relations clearly established. There are marked individual differences in the microscopic structure of the brain which may be expected to correlate with differences in behaviour and personality traits but their significance has not been determined.

The Basis of Sleep and Activity.—Rhythmic periods of rest or sleep and of activity are characteristic of all higher animals. The destruction of certain basal portions of the brain results in somnolence from which the subject may be aroused with difficulty. This suggests that normal waking activity may be sustained by reinforcement from these lower centres. If the suggestion is correct, the cessation of reinforcement during normal sleep still requires explanation. The accumulation of fatigue products has been proposed as the cause of sleep but their effectiveness has not been demonstrated. Reduction of sensory stimulation and the establishment of habitual rhythms of activity have been shown to be important factors in production of sleep.

Individual differences and diurnal variations in total activity have been extensively investigated. Genetic factors and a number of physiological variables such as the level of activity of different endocrine glands have been found to modify activity. Their mode of action is by altering the metabolic activity of the nerve cells, but details of this are not well understood.

Physiology of Emotion and Motivation.—Emotional states are usually accompanied by observable bodily changes. Rates of heart beat and respiration may alter, the skin flush, blood pressure rise or fall, the muscles tense. William James suggested that emotion consists of the sensations aroused by these bodily changes and a large number of studies seeking to relate specific emotions to such changes have been carried out. They have revealed great individual variation in the expression of any given emotion. Even laughter and weeping, perhaps the most definite forms of emotional expression, may occur inappropriately as in "weeping with joy," and there is no consistent relation between patterns of muscular activity and specific emotions. Facial expressions by which emotions are judged seem to be largely an acquired gesture language, likely to appear only in social situations and lacking in the congenitally blind. The accumulated evidence indicates that emotion is an altered level of general activity of the nervous system, an increase together with an impulsion to some activity, such as aggression or flight, or a decrease resulting in apathy and blocking of action. With increased activity there is excitation of the sympathetic nervous system resulting in a number of bodily changes which tend to increase the efficiency of skeletal muscle. From these facts Walter B. Cannon developed the theory that the bodily changes observed in strong emotions constitute a mobilization of energy in preparation for strenuous effort. The role of the hypothalamus and other nervous structures is described under that heading.

Emotional attitudes are important in motivating behaviour, and the study of emotions is one approach to the problems of the nature of interests and of incentives to activity. These problems have not been reduced to a physiological level, and physiological studies have been limited to investigations of hunger, thirst, the sex drive and similar primitive incentives. Such studies have revealed the susceptibility of the nervous system to specific chemical influences, the direct activation of sex activity or maternal behaviour by hormones in lower animals, increase or decrease of aggressiveness in primates under the influence of androgens or estrogens, activation of food seeking by sugar deficiency in the blood, and the like. Methods for direct study of their chemical action on the nerve cells had not been devised at mid-20th century.

Learning and Memory.—The problem of what changes take place in the nervous system during learning and the nature of the traces by which memories are preserved has given rise to innumerable speculations, ranging from the theory that learning involves a growth of new connections between nerve cells to the theory that nerve cells may secrete chemicals to which other cells become sensitized, by analogy with the development of specific allergies. No direct evidence in support of any of these theories had been obtained up to mid-century. Physiological studies had been limited to determination of the effects of various agents upon the rate of learning or in producing amnesia. The influences of age, sex, strength of motivation, of dietary and endocrine deficiencies, of fatigue, drugs, traumatic shock and various injuries to the nervous system are among the topics which have been intensively investigated. The results are complex, and no brief generalization of them is possible beyond the statement that any agent which retards the development or depresses the normal chemical activities of the brain tends to retard learning and impair memory.

Intelligent Behaviour.—Physiological studies have been confined to description of disorders of thought and behaviour which result from subnormal or pathological conditions of the brain. Agents which retard the growth of the brain, such as exposure to X-rays at certain stages of foetal development or thyroid deficiency in childhood, result in mental retardation. Toxic drugs may produce specific mental symptoms such as the vivid visual hallucinations of mescal poisoning or the euphoria of alcoholic intoxication, or they may produce a general slowing and confusion of thought. Injuries to the brain produce a variety of intellectual defects, which may be rather specific, such as the difficulty in finding words in mild aphasis, or may be a more general deterioration of comprehension and judgment. Small and sharply limited injuries are more likely to produce specific defects, large or diffuse lesions to result in more general deterioration.

Such facts are well established but their interpretation is still largely speculative. Intelligent, adaptive and creative behaviour is exceedingly complex and psychological analysis has made little progress in defining the various functions or capacities which contribute to it. An adequate adjustment to the situations of life requires that judgments be based upon consideration of a large number of relevant situations or memories. This capacity to deal simultaneously with a number of items is an important element in intellectual ability, and agents which disturb cerebral functions reduce the number of activities which can be carried out concurrently and integrated in final action. Thus, in perception, a patient with brain injury may be able to note one by one the various items in a picture but be unable to relate them to one another and so to comprehend the significance of the picture as a whole. Defects of judgment may result from a similar limitation of associative connections. In formal tests, the patient may be restricted in ability to classify objects, arranging them according to use but not by material or colour; he may be facetious or obscene where social custom forbids such behaviour. Limitations in capacity of this nature may be understood in terms of reduced number of associative connections or heightened thresholds of excitability, but there are many other processes which contribute to adequate adjustment and none of

them had, at mid-20th century, been adequately analyzed either in psychological or physiological terms. A physiological account of intelligent action was still an aim, not an achievement of science.

Applications.—Although physiological psychology was still far from an understanding of its fundamental problems, its discoveries had found many useful applications. Interest in the nature of retinal fusion and of seen movement led eventually to the invention of the motion picture. Other studies of sensory physiology had found almost equally spectacular application in the fields of illumination and communications engineering. School hygiene and safety engineering in industry and on the highway employ the results of many studies of sensory physiology, fatigue and reaction time. The science has contributed largely to the development of instruments facilitating night vision, flight at high altitudes, efficiency in desert and arctic conditions, etc. In medicine it was just beginning at mid-century to find applications in the treatment of nervous and mental disease.

Woodworth, *Elements of Physiological Psychology* (1911); C. T. Morgan, *Physiological Psychology* (1943). The last contains an extensive bibliography of publications on the subject. R. R. Gates, *Human Genetics* (1946); F. A. Beach, *Hormones and Behavior* (1948); and W. C. Halstead, *Brain and Intelligence* (1947), review important topics. C. J. Herrick, *The Thinking Machine* (1929), and C. S. Sherrington, *Man on his Nature* (Cambridge, 1941), are more general statements of the problems of physiological psychology. (K. S. LY.)

PSYCHOLOGY, COMPARATIVE concerns the study of similarities and differences in adjustive capacities and personality among the important types of living beings, from plants and unicellular organisms to the primates including man. It is currently interpreted as the science of lower-animal nature in comparison with that of man. A wide view of the subject held earlier by W. Wundt and others would include human comparisons now generally studied under the special titles of *Genetic* or *Child Psychology* (*q.v.*), *Abnormal Psychology* (*q.v.*), and *Ethnology* or *Folk Psychology*. The present article will be concerned with an examination of the psychological makeup and capacities of lower animals and man in comparison with one another.

Comparative psychology is studied not only because learning about the capacities of given animal forms is in itself interesting, and because of practical applications in fields such as medicine and animal training, but also because of its relation to human psychology. With the rise of an experimental comparative psychology and its rapid growth during the 20th century, the scientific study of lower animals has thrown much light upon questions in human psychology such as the early development of individual behaviour, fundamental impulses such as those involved in motivation, the nature of learning and methods of learning, and many others. Frequently human psychologists employ lower animals as subjects in their experiments, not only because these are easier to obtain in numbers and can be much better known as to background and better controlled under experimental conditions than human subjects, but also because of certain similarities in behaviour which can be identified dependably. It is possible to learn much about man by studying lower animals; moreover, the discovery of differences illuminates the similarities.

In primitive times man was forced to learn about animals because of his constant struggle with them for existence. There developed intimate relations with animals as domesticated members of the household, and in some cultures a mystical fear and worship of animals as enigmatic beings. The common-sense tendency to regard the actions and capacities of lower animals as similar to those considered prevalent in fellow human beings always has been strong in human society. People often talk to animals, appealing for action or for sympathy, and interpret their conduct as though dealing with other human individuals. One rather extreme development of this tendency has been the doctrine of transmigration of souls or metempsychosis, which holds that in other generations the human soul may reside in the body of some lower animal.

Through recorded history two different views have developed concerning man's relation to the lower animals, and on what basis he should compare himself with them. One, which may be termed for convenience the *man-brute view,* tends to stress differences often to the point of denying essential similarities altogether; the other, which may be termed the *evolutionary view,* calls attention to similarities as well as to differences. Aristotle formalized the man-brute view by attributing a rational faculty to man alone, and lesser faculties to the animals. Through Thomas Aquinas this provided a basis for the view of Catholic theologians that man possesses an immortal soul which sets him forever distinctly above and apart from other beings, which lack such an immortal soul. On the other hand, the rise of Darwinism in the 19th century led scientists to look for relationships between man, considered to be a highly evolved animal, and the other animals. This has come to be the modern view in science, and it is in this sense, and only for convenience, that the terms "man" and "animal" (*i.e.,* lower animals) will be used in this article. For scientific evidence indicates that continuity in the evolution of the organism has provided a basis for continuity of essential relationships in the evolution of psychological functions which exist, together with obvious differences, between lower and higher stages in the animal series.

Anthropomorphism.—There is an irresistible human tendency of long standing to ascribe human attributes, emotions and capacities, to other beings. Attributing human experience to lower animals is a form of anthropomorphism which became popular as an outgrowth of Darwinian evolutionism although it is far older in human history. It is an ancient human habit to think that, (1) "since I am of course well acquainted with my own thoughts and reasons for acting, because I am conscious," (2) "when I see other men and animals presumably behaving as I do, it follows that psychological causes equivalent to my emotions, impulses, and ideas, must be basically responsible." Thus it is said that moths and other insects fly to the light out of curiosity; the hen is proud of her chicks and wishes to teach them what she can; the rattlesnake sounds off in order to warn of his presence; pets and domestic animals are noble or sly and deceitful according to conditions, and so on. Jean de La Fontaine wrote his fables from the standpoint of anthropomorphism as opposed to the "animal-machine" theory of René Descartes, to prove that man is not the sole possessor of humanlike faculties. This view is recognizable today as one frequently held among writers of animal stories. Its validity is doubtful.

Although much interesting literature has developed through anthropomorphic crusades to prove that animal doings are based upon human traits, unfortunately such stories are always coloured to an unknown extent by the writer's prejudices toward humanizing his animal subject. The anthropomorphic attitude draws popular interest to animal doings, yet this practice involves two fundamental flaws which make it an undependable means of gathering evidence. In the first place it is typically grounded upon the usually unquestioned assumption that any individual is well acquainted with his own thoughts and psychological functions and even understands their causes. Upon this belief modern clinical psychology casts serious doubt, advising an attitude of caution on the part of would-be interpreters of psychological occurrences, particularly when untrained for observation or interpretation. Another difficulty is that a scientifically untrained individual, however well-intentioned, may be content to use a single outstanding occurrence in the life of an animal as a basis for his interpretation, especially one which has dramatic features making the telling and retelling of it a fascinating exhibitionistic act. But a single observation is low in reliability, especially when one's perception is influenced by his prejudices and preconceived notions. Furthermore, it is a well-known fact that with each retelling new features are unwittingly introduced and old ones changed so that the original observation becomes even less reliable than before. When it assumes the form of a consistent practice of interpreting the behaviour of animals on the basis of selected instances or stories believed typical, this tendency is called *anecdotalism.* Thus Plutarch in ancient Rome, La Fontaine in 17th century France, and countless other writers from early times to the present, have

busied themselves in reporting eloquent stories designed to disclose astounding mental capacities in lower animals.

Although the evolutionary position has been substantiated in its main contentions concerning mental relationships among animals, its real substantiation has come from experimental evidence and not from hearsay reports. The methods of anecdotalism, however amusing as literary exercises, lack the careful and critical examination of evidence which is demanded by the complexity of the problems. No statement concerning a psychological function may be held as sound if it grows out of an unchallenged and questionable report. Fact-gathering whether by observation or by experiment necessitates more than an interest in animals, it requires a special training in the scientific methods of investigation for which personal feelings alone are not a substitute. Even when an animal story is reported by a reputable person of veracity, there is no necessary assurance as to its soundness. Whether a given report comes from laboratory experiments or from observations of animals in their native habitats, it must be examined for dependability and subjected to certain questions, especially these: under what conditions and with what precautions against error in gathering and setting down facts,—were these findings recorded?

In comparative psychology as in science one generally uses the soundest method of study at hand. An observer of nesting behaviour in birds constructs a hideout or "blind" in order to minimize disturbances through his presence, and thereby gains *control* through excluding an undesirable distorting factor. By introducing a camera, binoculars and perhaps automatic recorders of the bird's movements, he further decreases the difference between his field investigation and laboratory experiments. A great proportion of the investigations in comparative psychology have been performed indoors in the laboratory, in order to obtain the maximal amount of control over conditions. There it is possible to regulate general conditions such as age and physiological condition of the animal subjects, to exclude disturbances, to vary environmental conditions such as temperature and illumination or keep them constant according to the experimental plan, and to introduce the special apparatus which is appropriate for ensuring accuracy both in the test itself and in recording results. Thus animal psychology has employed the maze method as one means of testing learning, special problem boxes to test intelligent behaviour, and a variety of other test situations all of which are designed to increase the reliability of the evidence which the experimenter eventually reports.

Interpreting Evidence.—The soundness of any interpretation obviously is limited by the validity of the evidence on which it is based. To illustrate how important it is to check evidence at the source before admitting any interpretation, let us consider one of the many cases in which special humanlike abilities have been claimed for performing animals. A horse named Hans, owned by Herr von Osten of Berlin, after long training, began to amaze audiences with his apparent ability to solve mathematical problems by tapping out the answers with one forefoot. Then, when a problem was written on the blackboard before him, the horse appeared to arrive at correct answers with such success that it seemed the owner's insistent claims for mental calculation on his behalf must be correct. Even problems in calculus could be "solved." Although the explanation of mathematical calculation was widely accepted by the public, inevitably there were expressions of skepticism, particularly among scientists. Many people suspected some trick; others thought that if the owner was honest the claims for calculation must be valid. However, scientific investigation carried out by Dr. Otto Pfungst of Berlin reached a different interpretation. In the first place, the horse was tested with Herr von Osten absent, with the result that he performed as usual; hence the owner's presence was not necessary and there appeared to be no trick depending upon him. In further tests it was soon discovered that Hans could not perform unless someone present knew the answer, showing that the operation somehow depended upon the direct influence of human individuals. Any assumption of telepathy was excluded by new controls. When Hans was blindfolded he could not give the answers, therefore a visual influence of some kind from persons present must be involved. The source of the cues was discovered when Pfungst and his assistants carefully watched the behaviour of individuals present who knew the answers. It was noticed that when a problem was presented such individuals would involuntarily bend forward very slightly, whereupon the horse would begin tapping. Hans would continue tapping while the person remained tense in this position, but when the proper number of taps had been made the questioner would jerk his head slightly upward, whereupon the horse would stop tapping. Slight movements of this kind are known to psychologists as the imperceptible changes in attitude which occur almost invariably when a person attending to an act of questioning recognizes that the correct answer is approaching. Although the observed minimal movements were exceedingly small, Pfungst concluded that these accounted for the presumed calculating ability of the horse merely by controlling the starting and stopping of his tapping. The facts justify the interpretation that, unbeknownst to his owner, Hans during his training had acquired the habit of tapping in response to visual cues. That such a habit and not calculation was involved was suggested by other circumstances, among them the fact that under the best conditions the horse could "do" the simplest problems no more readily than the most difficult. In agreement with this interpretation, "answers" to simple and complex problems alike often were incorrect by one or two digits, indicating that Hans had received his cue to stop tapping now somewhat too early and now too late. Still other indications in his behaviour favoured this interpretation, such as the fact that Hans usually would start to tap mechanically as soon as the problem was presented, without even looking at the figures written on the board before him.

This illustration brings out some of the principal characteristics prerequisite to an interpretation in comparative psychology. The interpreter does not insist upon his first hunch, but recognizes the need for a thoroughgoing investigation of the phenomenon under varied conditions, with control of every factor of possible influence. Thus in Pfungst's study of Hans the importance of vision, the presence of persons who knew or did not know the answer, and the behaviour of persons present, all were appropriately tested. When all possible evidence has been gathered through investigation, the experimenter then sifts and organizes it logically, perhaps with the aid of mathematical techniques, to find the explanation which best fits the facts. Whether the investigation is simple or complicated, and whatever its nature, the described safeguards are needed.

Adaptive Behaviour or Purpose.—Difficulties frequently arise in interpretation because of one's general point of view. Under natural conditions, for example, the behaviour of animals generally conforms rather strikingly to what would be called "appropriate" or "best" in the given situation by the human observer. Thus the hinged leaf of the Venus's fly-trap closes when a fly alights upon it, but not when stirred by a gust of wind; the scallop closes the valves of its shell tightly when the approaching starfish, its common enemy, is still at a distance; the octopus frequently remains secluded until its common prey, the crab, approaches closely; the chimpanzee, confronted with food out of reach, may be able to attain the food by means of a stack of boxes which he arranges. Acts which *seem* well adapted to the given animal's survival or welfare under particular conditions are often described as being "purposive." For those seriously interested in obtaining an adequate explanation, this generalization of purposiveness in behaviour raises certain difficulties.

The above cases are typical—what can be said about them? First, these are acts which occur substantially as described; the reports are reliable. We can also say that the acts have in common one characteristic: that each of them tends to further the life processes of the animal and to fit it to its surroundings by removing some difficulty. In this respect they are like the behaviour of a tailor fitting a suit, they are all *adaptive*. As thus defined, adaptive acts may and do vary widely in nature, from lower to higher levels in the animal series; for much of typical animal behaviour is adaptive. Although many theorists really

mean nothing more than this when they use the term "purposive" for behaviour, others do mean much more; hence it is necessary to continue the examination of these varied activities in the light of a distinction between what is "adaptive" and what is "purposive" in behaviour.

The names of Hans Driesch and W. McDougall are associated with the development of a view in the nature of *teleology* (Gr. *teleos,* an end, and Gr. *logia,* speech), through which directive forces comparable with human purposiveness or volition are regarded as present in all animal behaviour of the type termed above "adaptive." When a man behaves purposively, with the assistance of thought processes he bends his efforts toward attaining an end which he can anticipate or predict. If all animals actually performed their adaptive behaviour on the basis of such a volitional process in order to attain given anticipated ends, the problem of interpretation and explanation in comparative psychology would be relatively simple, since the same type of solution would apply to all cases. The difficulty is the ever-present danger that the teleological type of explanation may arise from the theorist's prejudices and preconceived notions rather than from a careful and systematic study of the evidence.

Morgan's Canon as a Guide in Interpreting Behaviour.—A useful rule in scientific interpretation is the *principle of parsimony,* which may be stated as follows: Of alternative explanations for a given phenomenon choose the simplest, that is the one which involves the fewest assumptions, provided it is no less adequate than the others to meet the facts. This principle was applied to comparative psychology by C. Lloyd Morgan, in the following terms: "In no case may we interpret an action as the outcome of the exercise of a higher psychical faculty, if it can be interpreted as the outcome of the exercise of one which stands lower in the psychological scale." (From C. Lloyd Morgan, *Introduction to Comparative Psychology,* Scribners.)

The purposive, anthropomorphic type of explanation for the above examples would be that the Venus's fly-trap *needs* food, hence closes in response to insects but not to inedible objects which touch it; the scallop *recognizes* an enemy in the starfish and closes its valves to avoid destruction; the octopus hides *so that* its own enemies will not see it and its own prey will pass close by; the chimpanzee stacks the boxes *for the purpose of* obtaining the suspended food. At first sight all of these purported explanations may appear simple; however it would be unsound to adopt any one of them until it had been examined in the light of Morgan's canon, and until possible alternatives had been considered. Actually, these explanations are all complex, because each is loaded with untested assumptions. Each of them assumes that the organism understands the nature of the situation as might a man (*e.g.,* the octopus somehow *knows* that it is out of sight when behind stones); furthermore there is the assumption that the animal foresees what will happen as the result of one action or its alternative (*e.g.,* the scallop anticipates being killed if it does not close its valves), and that these organisms are capable of weighing the possibilities and choosing the correct act as might a reasoning man. In each case the presence of humanlike capacities such as understanding meanings, anticipating results and choosing between alternatives is actually implied by the purposive type of explanation.

Morgan's canon would call for discarding the purposive explanation in any case of adaptive behaviour which the results of investigation reveal is based upon simpler processes. From this standpoint, the experimental evidence favours a purposive explanation in *only one* of the described instances. This is the case of the box-stacking chimpanzee, for which the investigations of W. Köhler and others show that the animal can anticipate failure when jumping from the ground to suspended food, can understand the significance of a box as a means of nearing the food, and is able to develop a solution for such problems through a process qualitatively resembling human reasoning. To account for the fly-trap's reaction, however, it is necessary only to assume a simple reflexlike reaction to a simple stimulus, for the halves of a leaf close together when the delicate central leaf filaments are touched by some foreign object. As for the scallop, experiments show that the valves are closed in response to a chemical effect of sufficient strength, since the scallop does not close its valves if the starfish appears behind glass (visual control) but does so when concentrated starfish broth is released in the water nearby. The assumption of an intent to hide in the case of the octopus is vitiated by an experiment of Bierens de Haan, who found that the animal would slip between plates of glass where it was fully in sight as readily as between pieces of slate. A simpler explanation in line with the facts is that the octopus comes to rest most readily when its body is well in contact with surfaces, hence frequently nestles in crevices—not because of an understanding of hiding.

The above cases illustrate simply the value of investigation in comparative psychology as a means of testing assumptions and reaching the most adequate explanation for each case. Too frequently a purposive account proves to be a mere naming of the results of given activities (*i.e.,* the animal is protected, or obtains food) without really explaining them. A name alone is not acceptable as an explanation, and in fact may suggest an incorrect line of interpretation. Rather, the explanation or theory which is advanced for a given phenomenon, from the closing response of the scallop to box-stacking in the chimpanzee, must grow out of evidence derived from actual investigation and not out of assumptions based simply upon analogies between the behaviour of lower animals and man. For experimentation has shown repeatedly that activities which appear to be very similar in that they lead to similar adaptive results (*e.g.,* both the leaf-closing of the fly-trap and the box-stacking of the chimpanzee may be termed "food-getting behaviour") may be very different in their psychological makeup. The uncritical assumption of abilities akin to human reasoning in all instances of adaptive behaviour must be judged no more helpful to scientific explanation and no sounder logically than is the dogmatic denial of reasoning or comparable abilities in all animals below man.

THE CRITERIA OF PSYCHOLOGICAL STANDING

Some Schemes of Psychological Levels.—On what basis may the psychological status of a given animal be judged? A belief of long standing in the philosophical background of psychology is that a fairly definite series of levels exists among human psychological processes which is paralleled by corresponding psychological stages in the animal series. The earliest elaborate development was the scheme of Aristotle with its four general levels: a nutritive faculty alone, possessed by plants; the addition of sensory faculties in the lowest animals; the addition of an appetitive faculty in the higher animals; the addition of a rational faculty in man. As another contribution to the speculative period, the ideas of Descartes embodied a simpler scheme: a lower level of animals viewed as automata, and man as the sole rational being on a higher level. In 1905 R. M. Yerkes offered a differentiation of levels based upon functional criteria: (1) discrimination, or a general form of reaction, characterized by the sea anemone; (2) docility, or modifiable reactions, characterized by the rodent; and (3) initiative or variability in reaction, characterized by primates. This scheme was one of the first to be offered on the basis of actual experimental tests of animal capacities.

The first criticism generally offered of such systems is that they are merely speculative and pre-experimental, or antiexperimental in that they tend to restrict the view of the experimenter. The objection is that such schemes tend to oversimplify animal nature, which is fairly complex even in the lowest forms of animal life, and encourage artificial interpretations of animal capacities. The sharp distinction of psychological levels is considered unnatural in other ways, for example in the implication that a given capacity is present in a qualitatively homogeneous form through all animals on a given level. For example, Jacques Loeb differentiated higher animals possessing associative memory (*i.e.,* governed by the energy properties of stimulation) from simpler forms; yet experimentation has disclosed not only a considerable overlapping of these divisions, but also much variation in the qualitative nature of learning and memory in different animal forms. Investigative experience has come to favour the view that schemes of "psychological levels" are a useful means of representing the transition

from lower to higher stages of psychological abilities, and are a desirable means of summarizing our knowledge concerning animal relationships so long as they do not imply an unnatural discontinuity from level to level.

Consciousness a Doubtful Criterion.—Attributing consciousness to any lower animal and speculating how it must feel to be that animal is an irresistible everyday tendency which has its formalized side in speculative philosophy. The general position is that when we see in another individual a behaviour more or less similar to our own, we are justified in attributing to the other individual, man or lower animal, a conscious experience similar to our own. Thus Michel de Montaigne thought that brutes must possess the power of imagination, because of occurrences like the startling and barking of dogs in their sleep. The origin of psychology in philosophy, and the domination of introspective methods in early experimental psychology, accounted for a prevalent tendency toward analogized consciousness at the time experimental comparative psychology began to develop late in the 19th century. For several reasons this tendency later changed considerably, partly because of opposition from physiologists engaged in behaviour work, but mainly through countertendencies in interpretation which developed from attempts to use consciousness as a criterion of animal mentality. The chief objections were two. First, the methods of introspection were judged uncertain in validity for human psychology, and worthless in studying lower animals which can not speak; also it was recognized that the method of analogy, which must necessarily be employed, is subject to basic deductive weaknesses. For if inferences concerning the qualitative aspects of even the simplest mental states in man are held doubtful, what can justify applying the method of anthropomorphic analogy to lower animals? In the words of M. F. Washburn (from *The Animal Mind,* 1926 ed., Macmillan company)

> We speak, for example, of an "angry" wasp. Anger, in our own experience, is largely composed of sensations of quickened heart beat, of altered breathing, of muscular tension, of increased blood pressure in the head and face. The circulation of a wasp is fundamentally different from that of any vertebrate. The wasp does not breathe through lungs, it wears its skeleton on the outside, and it has the muscles attached to the inside of the skeleton. What is anger like in the wasp's consciousness? We can form no adequate idea of it.

The attitude of behaviourists like J. B. Watson is to deny the validity of analogizing consciousness and to favour replacing the concept of consciousness with more objective terms in psychology.

The Objective Attitude in Comparative Psychology.—The development of behaviourism in general psychology was strongly influenced by events in comparative psychology. Particularly in the United States, the view gained ground early in the 20th century that the objective methods of natural science afford the only dependable means of studying and comparing animal behaviour. Careful study of an animal under controlled conditions should furnish evidence leading to a valid psychological description of the animal's capacities, without having to use analogies from the human level. Perhaps the chief contribution of this movement to the growth of comparative psychology was its emphasis upon developing objective techniques rather than relying upon traditional subjective procedures, for evaluating and comparing the psychological resources of different animals.

To appraise a given animal activity, the psychologist must consider not only the general nature of the activity under study and its adaptive value, but also the individual's background. He must take into account what factors in the characteristic organic makeup of the species have contributed to the act, as well as its relation to individual experience. For neither the stability nor the adaptive efficiency of a given animal's behaviour pattern are as crucial in determining the animal's psychological status as are the possibilities that appropriate changes in the pattern may occur under new conditions for which the individual is unprepared.

Ideally, the first necessity for comparative study is to understand as far as possible the characteristic behaviour capacities and resources of each animal type. Then it is not sufficient merely to assign positions in a series, describing some animals as inferior and others as superior; the basis of the presumed inferiority or superiority must be clarified through appropriate comparisons. The principal weakness of a topical study, which deals in cross-sectional fashion with subjects such as "emotion" or "learning," is that it risks the defects of faculty psychology by assuming, for example, that a "faculty" such as "memory" exists apart and distinct from other capacities, and that it takes the same form wherever found. The fact is that a given capacity, such as learning, overlaps other abilities and may be very different according to the animal type involved. Higher animals do not necessarily repeat the makeup of lower animals with the mere addition of certain new abilities. On the contrary, instead of a recapitulation in which the characteristics of lower animals are repeated in the higher, closer study may disclose similar factors in development (based on a common ancestry) which when merged with new factors assume *new* psychological significance. These matters may be illustrated by passing in review some outstanding differences observed among various types of animals.

CRITICAL POINTS OF CHANGE IN THE ANIMAL SERIES

Protozoa and the Concept of "Simplicity."—The Protozoa frequently are termed the simplest animals. This can not mean that their activities are necessarily few in number, for H. S. Jennings and F. Alverdes have shown that the movements of the ciliate *Paramecium,* for example, are highly diversified and variable according to conditions. This organism is propelled forward, rotating about its longitudinal axis, by the beating of minute hair-like cilia covering its slipper-shaped body. When a stimulus change is encountered the organism may pause momentarily, rotating narrowly or widely in place before continuing in a new direction, or may reverse its direction by backing through a shorter or longer distance at an angle varying from acute to obtuse. The behaviour itself is not simple, for the organic (protoplasmic) changes underlying the many variations of ciliary stroke in these different reactions are involved and little known; however, it *is* simple in the sense that each behaviour change can be understood as a direct reaction to a somewhat different stimulus. The specific properties of the stimulus appear to be critical, in particular its intensity; for example, a gentle contact typically elicits slight interruptions of forward movement perhaps without any backing, whereas strong contact elicits a pronounced backing reaction. A variety of evidence indicates that the physico-chemical properties of the given stimulus directly govern the extent and the duration of modification in forward swimming. This behaviour is not simple in the sense that there are few items in the animal's repertoire, but rather in the sense that it may be understood in terms of relatively few concepts. For the direct dictation of response by the properties of stimulation is the lowest order of psychological concepts.

Nevertheless, protozoan behaviour frequently appears surprisingly involved. When Jennings dropped carmine particles upon the disc of an attached trumpet-shaped ciliate *Stentor,* as the stream of particles continued to fall there occurred a series of reactions passing from an initial slight contraction of the oral disc (the region first affected) to more and more complete contractions of the entire animal which finally broke it free from the substratum. These successive reactions occurring under conditions of repeated stimulation have been viewed by some as a series of "trials," as Jennings described them. Others more objectively view the reactions as the consequence of a spread of protoplasmic change through the animal, with each repetition of the external effect producing a different reaction more widespread through the organism. At first only the funnel end reacts; then as the internal excitation spreads the stalk becomes involved, contracting farther and farther toward its attached base. Apparently complex as to its protoplasmic basis, the behaviour may be understood simply in terms of an accumulation of physiological changes capable of producing new results as it builds up and reaches more remote localities. The notion of "trials" emphasizes the adaptive possibilities of these changes, but at the same time misrepresents the psychological nature of the acts, which are forced by stimulation rather than being "trials" in the sense of *attempts* at given results.

The above case illustrates how, in the simple psychological system of the protozoan, variability in reaction widens the adaptability of an animal to surrounding conditions. Jennings demonstrated that paramecia collect around a drop of acid in their medium; not through direct approaches to the acid but because they first swim without interruption into the area, then recoil from the

FIG. 1.—(A) JENNINGS' OBSERVATION OF PARAMECIA COLLECTING IN CIRCULAR ZONE OF WEAK ACID AROUND A BUBBLE OF CARBON DIOXIDE. (B) PATH OF AN INDIVIDUAL PARAMECIUM AFTER ENTERING SUCH A RING AS SHOWN ABOVE

acid-deficient border area upon each chance entry. Since in the ciliates, altered stimulation typically interrupts forward swimming differently according to its intensity and other physicochemical properties, the organisms thereby are enabled to avoid many injurious agents in their environment. The adaptability of such reactions in unicellular organisms, together with the fact that they make possible retaining optimal (*i.e.*, most suitable) environmental conditions, stems from the fact that variable swimming persists until conditions recur favouring normal locomotion.

The status of behaviour changes in Protozoa has been much discussed. As examples of special changes which have been demonstrated, ciliates like *Paramecium* ingest less carmine after having taken in carmine particles for a time, and the effect extends for a time to each of the daughter individuals after the division of a satiated organism; *Amoeba* puts forth successively fewer pseudopodia before each further reversal of direction, when repeatedly exposed to bright light; *Paramecium* reverses more and more promptly when introduced successively into a narrow capillary tube from which it can escape only by doubling around. Some experimenters consider such changes equivalent to the "learning" of higher organisms, pointing to the similarity between graphic records of time- or movement-reduction in these cases and in the learning of higher animals. However, others stress the limited time during which such changes persist in Protozoa, also the fact that many of these behaviour changes have been duplicated without putting the protozoan through "trials," merely by chemical treatment, for instance. Perhaps the most relevant point favouring the latter and simpler interpretation is that the described changes soon disappear without leaving any trace of a lasting alteration of the typical species behaviour pattern.

Behaviour Organized on a Reflex Basis.—For an evaluation of internal organization underlying behaviour in the (organically) simpler multicellular invertebrates, the starfish and its relatives such as the sea urchin have been useful subjects. Experimentation has shown that the component activities of co-ordinated feeding, locomotion, and other common activities in these lower invertebrates may be regarded as true *simple reflexes*. In a simple *reflex arc* (*i.e.*, reflex circuit) there is an afferent neurone or specialized receptive cell (*see* NERVOUS SYSTEM) which when stimulated transmits energy impulses to a specialized motor cell which in turn arouses muscle tissue to contract. Thus, when we touch one of the mobile spines which cover the ball-shaped body of the sea urchin, nervous impulses pass from excited receptor cells at the base of the spine to motor cells and through them to muscles which move the spine. A weak stimulus arouses impulses which cause one set of muscles to bend the spine *toward* the side touched; if the stimulus is strong another set of muscles is aroused which bends the spine *away*. Other reflexes characteristic of the echinoderms include the responses of the pedicellariae, little jawlike structures which rise and snap shut when adequately aroused, and the *tube feet*, small fingerlike muscular structures capable of bending and adhering to the substratum by their terminal sucking discs. In all but the simplest types of reflex arc the receptive cell does not connect directly with the motor cell, but transmits impulses to it through the specialized internuncial or association cells of a centralized nervous system. Throughout the animal series the normal functioning of internal organs (*e.g.*, the heartbeat) or systems of organs (*e.g.*, digestion) is controlled by reflex arcs in a more or less automatic manner. In man, reflex processes occasionally intervene in general behaviour, as when one sneezes irresistibly in response to dust in the air. However, in higher organisms such reflexes have a very different significance from that in lower invertebrates.

In the echinoderms the prominent features of ordinary behaviour are activities such as those described for pedicellariae, tube feet, and spines. Actually, the effective operation of each of these types of equipment depends upon the local makeup of the given structure and not upon a more general control. When any one of these structures is cut free from the animal and appropriately mounted, it is still capable of responding to stimulation in its characteristic manner. Thus, independent spines bend toward the side on which weak stimulation is offered, and away from the side of strong stimulation; the long snap-pedicellaria closes to light touch and the single biting pedicellaria rises when stronger stimulation is presented, essentially as when these structures are present in the intact organism. The fact that local activities of this kind are coupled together to make up the body of normal behaviour in echinoderms led J. von Uexküll, who performed these experiments, to call the animal a "community of reflexes." The same term may be applied to the medusa or jellyfish form of the coelenterates, whose severed mouth-tube bends and takes food as in the complete organism when mounted and appropriately stimulated, and in fact to the local activities of lower multicellular invertebrates generally. Their behaviour pattern exemplifies the concept of "chain reflexes," of local and essentially independent activities which combine into series when appropriately aroused in the intact organism.

However, these local functions alone do not account for the unity and co-ordination observed in normal activities such as the locomotion or feeding of the starfish. The tube feet of this animal come into play in feeding, after the pedicellariae have held the prey for a time, because nervous impulses have reached them from the pedicellariae. These different structures are unified by a generalized web of conduction tissue called the *nerve net*, which is widely present in the body-wall and which links the action structures functionally together. The nature and arrangement of the nerve net are such that it conducts more or less equally in all directions, differences depending mainly upon the nature of ex-

ternal stimulation. Thus when one spine of the sea urchin is strongly stimulated at its base, the surrounding spines on all sides bend away from the locality, the reaction spreading until the spines of a considerable area have bent outward. However, if a circular cut is first made through the tissue around a given spine, the surrounding spines do not react when this one is stimulated. The nerve net exemplifies the function of primitive generalized conduction systems, which unify the local functions of the organism without determining the pattern of behaviour. In human behaviour such functions are very subordinate; for example, nerve-net tissue in the intestine permits the co-ordination of sections of the tube in normal digestion. However, in the adult sponge, one of the simplest multicellular animals, even such a generalized unified nervous structure is lacking, hence the contractile chimneys through which sea water enters the organism open and close independently through the action of external stimulation upon them separately.

Echinoderms such as the starfish possess a further degree of organization in behaviour. For example, when overturned upon their backs, the starfish and some of its relatives are capable of returning to the normal position. One pattern of righting typically predominates when previous stimulation and the handling of the organism in overturning it are regularized. This involves the twisting of the two or three rays of one side so that their tube-foot surfaces first touch the ground, then attach progressively farther toward the central disc. Their leverage raises and swings the body of the starfish until it falls overbalanced upon its ventral surface and is righted. For this to occur as described, it is necessary that the rays of one side do not twist and attach their tube feet. A. R. Moore has shown that if a cut is made through the nerve ring of the central disc, through which the radial nerves of all five arms are normally connected, when the animal is overturned all rays are caused to attach in an unco-ordinated manner so that righting occurs very slowly and abnormally if at all. This shows that normally co-ordinated righting depends upon the possibility that nervous impulses from the rays first to attach may reach the opposite side through the central nervous system and somehow inhibit (*i.e.*, interfere with or displace) the twisting and attaching of these rays. Thus through nervous function the normal unitary behaviour of such an organism rests upon the temporary subordination of certain local reflex activities to others which are themselves reflexes.

Such an interplay among the local functions of a community of reflexes illustrates one of the simplest ways in which an organization may be achieved in individual behaviour. Organizations attaining advanced degrees of elaboration and plasticity become possible when reflexes are dominated by wider patterns not themselves reflex, as when scratching a flea bite is inhibited in a dog when food comes in sight. Not only do reflexes themselves become more elaborate and diversified in higher organisms, as in the variety of reflex-cleaning activities of which insects are capable, but they also become related to other activities in new and more varied ways. Hence the concept of the reflex as such must be revised according to the given case.

Notwithstanding the known shortcomings of echinoderms in functioning as unitary individuals, Jennings reported experimental results which led him to endow the starfish with a capacity to learn. The starfish was overturned so that it must right itself, and in each repetition one particular pair of arms was prevented from leading the righting reaction by using a glass rod to separate the tube feet forcibly from the substratum. The results after 180 trials showed that the arms thus restrained took hold less readily than originally, an outcome which Jennings interpreted as "habit formation." However, A. R. Moore attributed the results to an injury of the restrained arms through use of the glass rod, so that they became less sensitive and more sluggish in the course of the experiment. He produced similar results without putting starfish through righting tests, merely by rubbing the tube foot surfaces of given arms with a glass rod or treating them with weak acid. In higher organisms, temporary behaviour changes forced by simple desensitization or fatigue of local structures are not ordinarily regarded as cases of habit formation or learning. It seems necessary to think of instances such as this as more simply constituted than the term "learning" would imply.

CONTRIBUTIONS OF A CENTRALIZED NERVOUS CONTROL

Cephalization and a Simple Brain.—The limitations of lower invertebrates are definitely improved upon in groups such as worms, molluscs and particularly insects. Basic types of advance appear in the behaviour of the earthworm. This organism is equipped with a specialized anterior end which is not only the most sensitive and highly mobile of all localities, but also the dominant locality by virtue of possessing a brain (superior nerve-ganglionic centre). This *cephalization,* or head dominance, permits reacting to a wide range of stimuli in fairly well-directed ways. In an experiment by W. Hess, for example, earthworms turned rather directly away from the source of strong light or toward the source of weak light. Thus a different basis of organization permits a much wider range of environment and action than is possible through the more limited organization of Protozoa and other lower invertebrates. The significance of a specialized leading part for more efficient locomotion and reaction is indicated by the fact that a marine worm deprived operatively of its superior ganglion crawls about irregularly, does not turn readily upon contact with a corner, and burrows less readily than does a normal worm. Such a specimen is incapable of extending directly from its burrow and precisely seizing a shrimp or other passing organism (a chemically-controlled reaction) as does the normal individual. The fact that the removal of the worm's superior ganglion does not completely remove such normal reactions, although it reduces considerably their directness and precision, indicates that at this stage the brain has a limited dominance as a more efficient transmitter of nervous impulses from the most sensitive regions of the organism, and not that its own makeup gives it a unique control over behaviour organization which is absent from other centres in the nerve cord. In the insects, on the other hand, the role of the brain has advanced from that of a *superior transmitter* to that of an *indispensable organizing centre.* Although a wasp or ant may walk about in a somewhat co-ordinated manner for a time after the head has been removed, before dying, only scattered reflex components of normal behaviour such as stinging may occur, and most of the complex normal behaviour repertoire (*e.g.*, the solitary wasp's ability to dig a burrow and parasitize prey) will be absent.

Organization of Precise Orientation.—The regulation of locomotion in relation to external stimulation undergoes a marked improvement in worms, molluscs and arthropods as contrasted with lower invertebrates. The tropism theory of Jacques Loeb emphasized the significant fact that, first of all, it is the evolution of a true bilateral symmetry and the specialization of a permanent anterior end which provides the basis for an increased scope and precision of orientation in space. In contrast to an echinoderm like the starfish or a coelenterate like the sea anemone, in which directionalized movement in response to light and other stimuli is typically deficient in precision, the higher invertebrates exhibit marked improvement. The improvement is seen first of all in behaviour such as total movements of the organism with reference to external stimulus sources, as when a snail turns toward the side on which a lettuce leaf has lightly touched a tentacle. At this stage it is not the nature of the object, but the crude energic properties of stimulation which are effective. For example, worms approach the source of a variety of chemicals, if weak solutions are used, but move away from the source if the same chemicals are intense; with intermediate concentrations of these chemicals the reactions are variable. The directive influence of differences in the intensity of stimulation acting upon receptors of the opposite sides of the body is indicated by experiments such as that of S. J. Holmes and K. W. McGraw, in which a cricket with covered left eye turned persistently toward the left when placed in strong diffuse light. Similarly, a normal animal turns to the left when a strong light is placed at its right.

Further improvements in the precision and variation of orientation become possible with the evolution of greater specialization in receptors and in nervous equipment (*see* ANIMAL BEHAVIOUR). The octopus, with some capacity for visual accommodation, moves

forward only when an object (*e.g.*, a crab) appears within a given range of distance; among insects which have compound faceted eyes some, like the honeybee, under appropriate conditions are capable of moving toward a single point of light stimulating one eye alone. Although the role of improved receptors appears very prominently in specialized orientation, advancements in nervous and muscular structure, particularly the first of these, are also essential. For example, cutting the nerve-fibre tracts which connect the two sides of a worm's simple brain, or much more so an insect's complex brain, greatly reduces the precision of normal movement with reference to stimuli. However, neither the accuracy of orienting movements toward or away from a source of stimulation, nor the nature of the receptor involved (*i.e.*, its complexity, or similarity to mammalian receptors) alone justifies conclusions as to the psychological status of the act. Numerous experiments indicate that on this level it is the specific quantitative characteristics of stimulation (*e.g.*, intensity, size, amount of change, rate of movement) which control the timing and precision of approach and withdrawal, rather than the qualitative nature of the object. Simple factors such as these appear to control the responses of the octopus, and the fact that it has a well-developed lens eye approaching that of many mammals in complexity does not mean that it "recognizes" its food as do higher mammals. Bierens de Haan found that when an octopus was presented with a crab in full view within a glass jar, the crab was seized only when a tentacle chanced over the rim of the jar into contact with it, without any directive aid through vision.

Simple Learned Modifications.—The improvement of behaviour organization through learning first occurs in the flatworms, in which conditioned-response changes have been demonstrated. Light ordinarily causes the marine flatworm *Leptoplana* to move about, whereas local contact stops locomotion; however, after 25 five-minute periods in which light was coupled with a tactual stimulus, the worm remained quietly in the light without movement. Similarly, M. Copeland trained the marine worm *Nereis* to appear from a glass tube when it was lighted, or when it was darkened, depending upon which of these visual changes had been combined with meat juice during the training period. In the earthworm a specific movement in space may be acquired through learning, as in the experiment described below.

The subject was introduced into a glass-covered T-shaped alley system in which a turn to the left at the junction brought the worm into contact with an electrode delivering an electric shock, whereas a turn to the right brought the subject into a dark box. Within 160 trials the problem had been mastered by many of the worms, which then turned consistently to the right upon leaving the entrance alley. That the habit was not dependent upon a simple localized sensory or muscular change was indicated by results when the positions of electrodes and dark box were reversed after original learning. Worms which had learned to turn to the right side now reversed their trained turn to the left within 75 trials, a distinct saving which indicated a central nervous basis for the learning.

The organization of behaviour would appear to be considerably enhanced by the capacity for learned modifications. The capacity for simple conditioned responses and for the simple changes in directed locomotion of which worms are capable, must alter some of the normal activities of these animals, although not to the extent that learning influences higher invertebrates. Illustrated by the conditioned response, which may be regarded as its simplest form, the essence of learning is that through experience under given conditions a particular reaction is given to stimuli previously incapable of eliciting such behaviour. In Copeland's experiment with the marine worm, light (the new or *conditioned* stimulus) initially was not effective in causing the worm to appear from its tube. Meat juice, however (the original or *unconditioned* stimulus), was effective; and the application together of these two stimuli produced a changed organization whereby light possessed a new type of control over reactions. In the T-maze behaviour, although somewhat more complex, there is a similar occurrence in which certain stimuli encountered near the junction acquire control over the right-turning reaction so that actual contact with the electrodes is no longer necessary. In such learned acts a new sensory-motor organization is involved, more lasting than the limited changes of which lower invertebrates are capable because it is not restricted to local sensory or motor changes alone.

FIG. 2.—CONDITIONING THE MARINE WORM NEREIS. AT FIRST LIGHT (NEW STIMULUS) AND CHEMICAL (ORIGINAL STIMULUS) MUST BE COMBINED ON EACH TRIAL; FINALLY LIGHT ALONE BRINGS THE WORM FORTH

An adequate organic basis for such accomplishments is afforded particularly by a central nervous system with sufficiently evolved ganglionic centres and interconnections to permit new sensory-motor reorganizations to arise under appropriate environmental conditions. The mere possession of a centralized nervous system with ganglion cells is not sufficient, for the starfish with its simple conduction system has not been demonstrated capable of true learning. Work on higher organisms has demonstrated that the further evolution of centralized conduction patterns gives rise to new possibilities in the complexity and qualitative nature of learning.

Instinctive Behaviour at Its Maximum.—The arthropods and especially the insects greatly exceed lower vertebrates in the complexity and diversified specialization of their activities. It is in this group that the problem of *instinct* (Lat. *instinctus*, impulse) comes prominently to attention. Of course, the mere application of the word "instinct" does not explain any act, and a variety of viewpoints is found in the literature, from the attempt to explain instincts as chain reflexes to the idea that the animal possesses an inherited awareness of a given plan of action. It is difficult to find adequate criteria for what is essential of so-called instinctive activities. Commonness to all members of a species requires the proviso "under given conditions," as well as the exclusion of common activities ordinarily *learned* by most members of the species. Most adequate is the criterion that "instinct" concerns activities which depend predominantly or wholly upon the nature of the animal's inherited organic equipment as played upon by given environmental conditions, with learning absent or in a minor role.

In this sense the activities of invertebrate animals in general are "instinctive," in that the action of certain typical environmental stimuli upon an inherited organic equipment of given nature results in a predictable kind of behaviour. These behaviour patterns and their component activities (*e.g.*, the starfish's righting response; the spinning of webs by spiders) are typically very adaptive, as noticed earlier in this article. However, such adaptiveness can not be attributed to psychological factors of purposive character in the given individual; for example, the fact that one species of solitary wasp stings spiders, another species caterpillars, can not be interpreted as a "seeking out" of the respective victims as a man singles out an object qualitatively. T. W. Ziegler has pointed out that the "purpose" concept generally depends upon a misunderstanding of the actual nature of the act. Thus the dragonfly lays its eggs upon water, not because the individual anticipates the development of the young in water, but because when gravid it is caused to react in this way to a shimmering surface. This explains why the eggs are frequently laid non-adaptively, for instance on a freshly tarred roof which gleams in the sunlight. The typical adaptiveness of "instinctive" acts can only be understood as a result of the long evolutionary process which has produced in the given species an equipment of sense organs, nervous system and muscles capable of such and such reactions when aroused in particular ways in a given environment.

To understand the nature of particular acts, it is essential to discern the particular organic circumstances under which they occur, and the environmental factors implicated. For example, the larva of the moth *Myelois* develops from an egg which is laid in the head cluster of an herb. The larva feeds upon the plant until mature, then leaves the herb and enters the stem of a

nearby plant such as a thistle within which it develops into an adult. A critical phase of the act concerns failure to remain within the herb. É. Rabaud varied temperature, humidity and other environmental conditions in an attempt to discover the cause; however, regardless of such changes the larva would remain in almost any place but the herb once it had ceased to feed and had matured. The evident basis of the act was an avoidance response to the essential chemical of the herb, apparently introduced by organic changes occurring at maturity. On a similar basis the larvae of many plant-feeding Lepidoptera become positive to gravity and negative to light upon reaching maturity, whereupon these larvae descend from the food plant and enter the ground where they enter pupation.

Such behaviour may be regarded as automatic in the sense that it occurs in dependence upon the arousal of particular organic equipment such as sense organs, and often upon the attainment of a particular physiological condition. To illustrate the latter, J. H. Fabre in his argument for the "inflexibility of instinct," reported that mature mason bees can perform only once the action of biting their way out of the paper cells in which they pass their pupation period. However, L. Verlaine found that within the first day after their original escape the young individuals could repeat the act, unless the material closing the cell was too hard or tough for the strength of their biting reflexes. Fabre was mistaken in his conclusion because he tested misrepresentative conditions. That an apparent "inflexibility" really depends upon the existence of a given organic condition may be illustrated by the fact that spiders can repair torn webs, or not, depending upon the condition of their different spin-glands; and dispossessed caterpillars can construct new cocoons unless they have reached an advanced stage at which their supply of silk is nearly exhausted. The performance of different functions according to age in certain social insects has been attributed by G. Rösch and others to given structural changes depending upon growth. For a time after first emerging from pupation, the young worker honeybee specializes in feeding larvae; however, brood-feeding ceases when the salivary glands atrophy at the 15th day, whereupon the young worker busies herself mainly in comb-construction and other activities within the hive. This specialization persists through the period when the wax glands are in their most active secretory condition, then at about the 25th day the bee begins her activity as a forager outside the hive.

That it is the organic factors (such as given visual organs, etc.) and not the "behaviour pattern" itself which the insect inherits is indicated by experiments such as those of W. H. Thorpe. Normally the ichneumon fly *Nemeritis* lays its eggs upon the larvae of the flour moth, upon which the ichneumon larvae feed as they develop. However, when ichneumon larvae were raised experimentally upon larvae of the bee-wax moth, later as adults they laid their eggs parasitically upon these insects instead of the normal prey, the flour moth. Such findings suggest that the selective stinging or ovipositing responses of adult females in parasitic insects such as solitary wasps (*e.g.*, one species to bees; another to spiders, etc.) are based not only upon the evolution of factors such as chemical receptors of given sensitive properties, but also upon a *learned* habituation to a particular chemical as a characteristic part of its early environment. That a similar learned adjustment is involved in the "nestmate recognition" of social insects is indicated by experiments upon artificial mixed colonies of ants. Individuals of four or five different species which have lived together in a common nest from the time they are artificially removed as new or callow workers from their cocoons, attack members of the colonies from which they were originally removed, but not their accustomed nestmates. Evidently they have become habituated to a composite of the different chemicals established in the unusual nest situation, so that the nest chemicals of their respective species are disturbing to them.

Many other results show that the inherited organic factors which underlie so-called instinctive activities require given environmental effects and frequently require the influence of learning in some form if the characteristic behaviour patterns are to appear. Certain findings for social insects such as ants indicate that the learned modification of given early reflexlike responses (*e.g.*, automatic regurgitation of food upon tactual stimulation of mouth-parts) provides a basis for the development of more complete behaviour such as approaching and feeding other individuals of the colony. It is quite possible that the following of odour-trails as in many ants comes into being as an extension of the individual's earlier habituation to a given chemical within the nest. Thus an alternative to the rather mystical view of insect social behaviour as a set of "instincts" is that while certain specific inherited organic factors are essential, the pattern depends for its nature upon a characteristic environmental situation and individual habituation.

In evaluating the status of insect activities, certain other ways in which learning appears in their lives must be considered. Honeybees and other social insects have been shown capable of learning simple discriminations between wave lengths of light (colour vision), as well as between figures of different outlines. Honeybees and ants have been trained to visit a food-place at one or in other cases two particular times of day, by presenting food only at such times during the training. Other tests show that this ability, called "temporal memory," depends upon stimuli from internal processes which arouse the insect after training. Ants of certain species have learned maze patterns of some complexity. All of these instances involve a marked elaboration of the capacity for orientation over that found in lower vertebrates, in which a tropistic orientation directly forced by stimulation is predominant. Nevertheless, the manner in which insects learn and the complexity of some of their habits does not prove to be more than a secondary factor in their behaviour. Their behaviour, like that of invertebrates in general, is species-stereotyped and dominated by factors arising through organic inheritance. (*See* Social Insects.)

THE FUNDAMENTAL VERTEBRATE BEHAVIOUR PATTERN

The possibilities of vertebrate organization, in particular of the tubular type of nervous system with its anterior brain (*see* Brain), are not very fully realized in cold-blooded vertebrates and birds. The control of locomotion and equilibrium is substantially as well developed in the lowest vertebrates as in mammals, illustrated by the versatile three-dimensional movement of fishes in their aquatic medium; however, the mammals are greatly superior in their capacity for individually new behaviour in response to environmental difficulties.

Contributions of Growth or Maturation.—Through the work of G. E. Coghill in particular, the appearance of basic vertebrate activities such as locomotion and the feeding lunge has been traced to the growth of different components of reflexive sensory-motor arcs in the nerve tube. Coghill's method in studying the appearance of fundamental activities in the salamander, a tailed aquatic amphibian, was to observe closely all new changes in behaviour and for corresponding ages to make parallel studies of the growth of nervous tissue in detail. For example, there was found an early nonmotile stage during which the animal does not move at all unless the muscles are stimulated directly; at this stage no nerve cells have developed connecting sensory surfaces with muscles. Then at about 30 hours of age there gradually enters a bending of the head away from the side stimulated, a response based upon the growth of cells in the nerve tube conducting impulses from the stimulated part of the skin to efferent (motor) neurones which arouse muscles on the opposite side of the neck. Coghill traced the appearance of the complex S-movement of swimming in this amphibian to later and more complex growth changes in the nerve tube. The work shows that in the development of swimming in this organism, the appearance of successive modifications in behaviour depends upon the growth of new types of connection in the nervous system. The organism may be drugged to prevent movement through the early period of development in which swimming normally appears, yet upon recovery swimming appears as in normal animals, by virtue of previous organic growth in the motionless specimens. Although these mechanisms are much more complex than those described for lower invertebrates such as the starfish, they are substantially on the same level of reflex-integrated behaviour.

Broadly speaking, the innate reflexive and structurally-dependent components are dominant over behaviour in the lower vertebrates from fishes to birds. Characteristically, activities such as those involved in feeding and mating are governed by the discrete (*i.e.*, separate) and partial characteristics of a situation, such as the visual-movement effect of an object, rather than upon its nature as a whole. Fishes, amphibians and reptiles tend to give their respective forms of the characteristic vertebrate forward lunge irresistibly in response to the movement of objects in the visual field. In one experiment frogs struck repeatedly at a fly surrounded by a ring of sharp points; in another, all attempts to train toads to snap at motionless mealworms turned out negatively.

Factors Limiting Modification.—To be sure, modifications are possible within limits through conditioning. Fishermen find that artificial bait is most effective when the given fly or plug resembles the prey upon which the fish are feeding at the time. Minnows have been trained to inhibit their initial snapping responses to chalk falling through the water, while continuing to respond to pieces of bread as before. The learned habits of lower vertebrates, like their unlearned responses, are dominated by the effect of discrete stimulative properties. However, it frequently happens that given discriminations can not be learned, because of interference from unlearned factors. In an experiment with the lizard *Lacerta,* H. Ehrenhardt found distinct limits to the possibility of training, where it opposed unlearned responses. Initially the animals were tested in their responses to simple geometrical figures which were moved before them against a black ground. Their spontaneous lunges were elicited most readily by the movement of figures with even outlines, such as circles; least readily by figures with broken outlines, such as triangles and crosses. In an attempt to change this state of affairs, a training series was conducted in which the preferred circle was always presented with a quinine-treated mealworm mounted before it, the less-preferred cross with an untreated mealworm. Yet within 850 trials no effective modifications of the original responses appeared.

In submammalian vertebrates it is not the nature of the object, but the discrete properties of the stimulus (*e.g.*, movement, size, brightness) which are adequate to elicit responses. K. Lorenz uses the term "releasers" for stimuli which characteristically arouse given types of response; however, this concept has been criticized as too simple and not emphasizing the actual nature of effective stimuli. The problem is far from easy. For example, the characteristic mouth-opening response (gaping) of young birds in many passerine species is elicited at first only by mechanical stimulation, vibration or movement of the nest; later it is given to the visual stimulation presented by any object (*e.g.*, a black disc) which is larger than one-eighth inch, moving and above the horizontal visual plane of the nestling. Then the young bird tends to gape toward the highest part of the stimulus object, especially at any small protuberance in that part of the figures. The facts suggest that at first the young bird reacts on an unlearned basis to very general stimulus properties, but gradually becomes conditioned to respond to special features of the external situation which have accompanied feeding (*e.g.*, protuberances resembling the head of the parent bird above its body at the edge of the nest).

In submammalian vertebrates the behaviour repertoire appears mainly through arousal of inherited structures in a given environment, with learning subordinate. This is true in the birds, which have a particularly rich equipment of natively-determined activities. In many of these, like migration, it is difficult to discern any essential contribution of learning in the principal acts. Migration in the spring, as it occurs in birds like the junco, evidently is set off through the attainment of internal changes (in pituitary glands, sex glands, fatty tissues) caused by the progressive springtime increase in daily illumination. Birds migrate in the wintertime, if this environmental change (*i.e.*, increasing illumination) has been duplicated experimentally. The direction and the main course of migration, when better known, may also prove to be based upon unlearned factors (*e.g.*, temperature gradients, food supply). The case is different for activities such as homing and pecking, for which experience seems indispensable. Thus, for a pigeon to return dependably from unknown territory, the bird must receive a systematic early training in which successive returns to the cote are made over increasing distances in a given direction. Other activity patterns, such as pecking in the domestic fowl, seem to depend upon a post-hatching process involving learning, in which certain early reflexlike activities are modified and integrated. Shortly after hatching the component activities (head lunge, bill opening and closing, and swallowing) are essentially independent; however, through a gradual process of improvement a fairly well-organized and accurate pecking response appears within four days. Chicks which are fed artificially and kept in the dark for a few days must go through the same process of gradual improvement, although in their case it occurs more rapidly, in part because of organic advantages such as greater muscular strength. Chicks which are artificially delayed longer than two weeks can be trained to peck at food only with great difficulty, since they have learned to feed in other ways than by pecking. Thus it can not be said that maturation or growth dependent upon hereditary factors contributes the *pattern* or organization of pecking in the chick; rather, it contributes the individual components (swallowing, etc.) which must be organized together according to experience. Other evidence indicates that although the chick pecks at small bright objects without benefit of learning, it can discriminate between edible and inedible objects only on the basis of early experience in pecking.

In reptiles and birds, although learning is still subordinate to unlearned factors in the development of behaviour, it contributes more in general than in fishes and amphibians. In the lower vertebrates generally, psychological organization is limited not only by a domination of unlearned factors, but also by a characteristic lack of plasticity and scope in learning. The habits, simple or complex, tend to be controlled by limited features of a situation rather than by broader aspects to which mammals can learn to react. For example, in an experiment by J. Porter, sparrows learned to open a puzzle box containing food by pressing either one of two parallel trip strings which operated the door. Then the strings were moved farther apart; this prevented the birds from opening the box, since the subject's response was to alight where a string had been, instead of responding to either string in its new position. Rather than learning how to open the door, the bird had merely acquired the stereotyped response of alighting in a particular spot, which scarcely prepared it for adjustments to changes in the situation.

The Brain and Behaviour.—To understand the basis of the characteristic deficiencies of submammalian animals, as contrasted with mammals, it is necessary to consider the function of the nervous system in the organization of behaviour. Behaviour organization is restricted to a low level in invertebrates like the starfish, in which adequate nervous interconnections are few and the dominance of available centres is greatly limited. In the worms there is an advance in the sense that a principal centre has appeared, yet it dominates largely as a superior transmitting centre rather than an organizing centre. The insect brain is superior in function, yet its organizing influence is rudimentary, as is shown by the fact that the activities which appear are always coloured by the characteristic reflexive properties of lower centres or of local functions.

A similar condition prevails in the lower vertebrates. As comparative neurologists, and in particular C. J. Herrick and C. Ariëns Kappers, have shown, the brain of the inframammalian vertebrate exercises only an incomplete control over the lower reflexive systems. Below mammals the brain is not yet capable of discharging unitary patterns of impulses to lower centres under the influence of many sensory aspects of a situation. Instead, the olfactory system centred in the forebrain, and the visual system in the upper midbrain, are interrelated poorly for activities beyond reflexive types. This accounts for handicaps such as the described inability of lizards to learn the inhibition of a strongly visually-dominated response. An improved correlation of the principal receptive centres of the vertebrate brain becomes possible through the appearance of a specialized type of tissue known

as neopallium (new brain) or *cerebral cortex* (*see* BRAIN). True cortex is present as a small laminated area in the upper forebrain of some reptiles and less clearly in birds, but in mammals covers the entire surface of the forebrain. When the principal centres of the central nervous system are interconnected directly and indirectly through cerebral cortex, its presence permits the overriding of reflexive types of behaviour by patterns organized in dependence upon the wider aspects of an experience. It is the evolution of cortex in particular which is responsible for the greatly broadened capacities of mammals for new behaviour.

PSYCHOLOGICAL SUPERIORITY OF THE MAMMAL

In the mammals from marsupials to man, the psychological limitations of lower animals are overcome to an increasing extent. In keeping with more versatile capacities, the world of the individual animal becomes increasingly wider and varied. The range of these capacities is broad, evidencing itself particularly in the resources of individuals for acquiring appropriate ways of behaving in new situations.

Development of Behaviour in Mammals.—Correlated with the longer infancy and childhood which characterizes mammals in general, conditions favour the accumulation of a far greater fund of new behaviour patterns than in inframammalian animals. This is particularly true in higher mammals such as primates. In general, the higher we go in the mammalian series, the longer the time required for the processes of organic development (especially growth of sense organs, nervous system and muscles) called *maturation.* Accordingly, behaviour processes which are closest to reflexes and require the least learning appear earlier in most lower mammals than in higher. For example, the young opossum at birth is able to crawl from the cloaca over the mother's abdomen to her pouch, by virtue of the fact that at this early time (just 12–15 days after development began) its forelegs are capable of pulling it along as the abdominal hair of the mother is grasped reflexly. At this stage the hind legs are virtually useless. Once in the pouch it becomes attached to a nipple and remains for several weeks, but after 60 days occasional excursions are made to the outside, and the animal has become capable of running and climbing well. In contrast, although at birth the human infant has a hand-grasp reflex sufficiently strong to support its weight for a minute or two, crawling typically does not take place until after 8 months of age and independent walking until after 15 months.

Even with their more rapid maturation, lower mammals typically are poorly equipped for coping with the external environment at the time of birth. Newborn kittens and puppies are essentially embryos, although capable of activities such as the sucking reflex and a crude righting response. Adequate external adjustments of the adult type appear slowly. Although it is recognized that growth contributes heavily to basic activities such as walking, the roles of environmental conditions and learning are not to be excluded in any case.

Influence of Environment and Learning.—Traditionally, activities appearing at or shortly after birth, or activities appearing widely through a species, have been considered inborn and "instinctive." Yet it has been objected that in the typically gradual appearance of activities in the developing mammal prior to birth, simple conditioned-reflex learning is possible, and furthermore, under much the same postnatal conditions all members of a species may be influenced by learning in similar ways. For example, Z. Y. Kuo has shown that the appearance of the characteristic mouse-hunting response of kittens depends to a large extent upon the kind of environment in which certain structural equipment is called into action. The first appearance of the act of pouncing upon a mouse is not "hunting," but is merely due to the fact that seen-movement excites the kitten to dart forward. This response is somewhat similar to the more stereotyped forward-lunge of lower vertebrates. In the kitten, what act becomes established depends upon prevalent conditions. In the characteristic environment, pouncing leads sooner or later to the taste of blood, since the kitten inherits sharp claws capable of puncturing the mouse's skin. The taste of blood stimulates feeding, and after a few repetitions the mouse-killing act is established. Under other conditions different results arise. By shocking kittens from the first in the presence of mice, the pouncing response was displaced by a fear reaction. By having kittens live continually in the presence of mice their responses to mice became those of social companions. The results indicate that while the inherited construction of the kitten is such that it readily makes given responses, organized patterns of behaviour such as mouse-hunting must be built up through experience.

Effect of Heredity Typically General.—It can be said that the specific influence of hereditary factors is much greater in the lower mammals than in the higher. For example, sexual activities appear less stereotyped in chimpanzees than in rats, and their organization evidently is much more influenced by experiences such as those in play. But for mammals in general, hereditary physiological influences limit and bear upon behaviour in broad and indirect ways, instead of determining the composition of particular complicated acts as in lower animals. It has been shown for example that the basis of the characteristic docility of the albino rat as contrasted with the savageness of the gray Norway rat is physiological and hereditary. Wildness is dominant in the progeny, which shows wildness-tameness in Mendelian proportions when further crosses are made (*see* GENETICS). The increasing difficulty, as puberty approaches, of controlling the previously tame domesticated young of ordinarily savage forest animals, such as the cats, suggests that glandular secretions play a part in species differences of this type. Similarly, when under the influence of the glandular changes incident to bearing young, mammalian mothers of various species are likely to show an increase in irritability and aggressiveness. Such factors tend to oppose or distort the capacities of an animal for intelligent behaviour, and their presence to variable extents in mammals high and low in the group adds difficulty to judgments of relative intelligence.

Of all animals, it is man himself whose adult behaviour pattern is the slowest to appear and the least dominated in final makeup by maturation. In a study in which a human infant and a chimpanzee infant were raised from birth in the same household, with a similar treatment, the benefits of more rapid organic maturation at first were all in the young chimpanzee's favour. At the age of five months it had reached a performance level exceeding that of the human infant at one year, exhibiting activities such as climbing, manipulating objects, and responding to individuals around him. The superiority of the chimpanzee in the co-ordination of progression and other general activities continued; however, the human infant presently began to excel in other respects. After he had reached the age of one year, with the appearance of the first true word-sounds, it became clear that in accomplishments such as mastering new meanings of objects and responding to adults, his accomplishments lay well beyond the chimpanzee's limitations. It is evident that the psychological superiority of the human individual over other mammals rests not merely upon his longer preparatory period of infancy and childhood, but his capacity for acquiring new and increasingly plastic adjustments to things and individuals around him during this period.

Drive and Motivation in Mammals.—Certain classes of behaviour once spoken of as "instincts" have become understood more clearly in modern experimental psychology as products of organic "drives." Drive is a term for a particular physiological source of nervous energy promoting activity in the individual. Examples of major drives are thirst, sex, hunger and, under special conditions, parental drive. Each type of drive-energy is known to arise from a rather distinctive type of physiological condition: for instance, the hunger drive emanates chiefly as nervous impulses from the rhythmic contractions of a fairly empty stomach; the sex drive from complex conditions centring around the secretions of the sex glands. The individual drives tend to have identifiable rhythms, each increasing and decreasing in a characteristic periodic way. The dependence of rhythmic changes in general behaviour upon internal drive fluctuations has been established in many experiments, for different animal forms and for man. An interesting study by G. H. Wang demonstrated

a relationship between the oestrous (egg-maturation) cycle and the daily amount of activity in the female rat. Each animal was kept in a small cage, from which it could enter an adjoining revolving wheel when prompted to exercise. A cyclometer attached to the wheel recorded the total amount of activity for each day, and parallel examinations were made of the rat's reproductive tract for signs of oestrus. It was found that the oestrous or heat periods came regularly at 4–5 day intervals, and at corresponding times there always occurred marked increases of activity in the females. This activity rhythm did not appear in the immature female, and it disappeared in the mature female after spaying, during pregnancy, or after menopause.

Drive signs such as stomach contractions have been demonstrated in animals from molluscs to man, and their influence upon behaviour has been identified in a variety of instances. Some broad distinctions may be made in the types of responses given by different animals to drives. Invertebrates and lower vertebrate animals tend to respond to specific stimuli in characteristic tropistic or reflexive ways when these stimuli are encountered by a drive-aroused individual. For example, a female burrowing-wasp of given species, fertilized and laden with mature eggs, stirs about and is especially excited to sting a spider when one is encountered; the egg-laden female jewel fish is particularly attracted by the movements of an individual of brilliant coloration and adequate size. The effective stimuli are essentially unlearned. The potency of movement to excite the feeding responses of lower vertebrates has been mentioned. In contrast, the object or incentive which attracts a hungry mammal tends to be discriminated from others on the basis of stimulus properties governed largely by individual past experience. The peculiar individual food habits of many pet dogs and cats illustrate the point. The increasingly broadened and specialized responses of mammals to drives depend upon a superior capacity for learning differences among environmental conditions. There is also an important difference between lower and higher mammals, which comes to a head in primates and especially man: the acquisition of the ability to have a drive-tension satisfied or lessened by objects or conditions only indirectly related to the original incentives. A pat on the head stimulates a trained dog to further efforts, but a rat can acquire such special learned control only slightly if at all. Chimpanzees may be trained to work for poker chips which later may be inserted into a food-delivery slot; thus the inedible object itself acquires a measure of drive-satisfying effectiveness for the animal. This is a capacity for symbolic satisfactions which reaches its greatest development in the highly indirect power of words over human motivation.

Sensitivity and Perception.—There have been many attempts to describe the world of the lower animal, on the basis of what is known about its sensitivity. Thus one might speculate that for the honeybee a flower patch is a pattern of colour and even conveys to the insect peculiar glimmers of ultra-violet here and there; to the bird skimming low the patch is vari-coloured without ultra-violet effects, whereas for the house-cat stalking the bird, the scene has a washed-out and colourless tinge. Such descriptions have the vagueness of all inferences concerning animal consciousness.

To be sure, the first step in understanding an animal's effective environment is to explore its sensitivity. A basic type of investigation in animal psychology concerns these three problems: what types of stimulation the animal is equipped to sense; what are the upper and lower limits (thresholds) of sensitivity in each of the sensory fields; and what is the acuity (*i.e.*, the degree of sharpness) in each field? In the general sensory equipment of animals countless striking differences are found. There are animals living altogether in darkness, such as cave-fishes, or below the surface of the ground as does the mole, which are very deficient visually or completely blind while possessing a well-developed olfactory sensitivity. Others, like most birds, have well-developed visual sensitivity but are poor in olfaction. Many insects, such as the housefly and the honeybee, although lacking visual sensitivity to the long wave lengths of light (seen by man as "red") are visually sensitive to the rays shorter than those seen by man and most other animals (the ultra-violet band). Some animals such as the cat and dog are insensitive to differences in the wave lengths of light which affect man as colours or hues, whereas others such as the honeybee, many fishes, most birds and monkeys possess a distinctive sensitivity to wave length differences more or less similar to that of man. While we can not prove that these animals can see hues as does man, the objective facts are similar, since in critical tests they can distinguish given wave lengths of light (*e.g.*, 575 mμ, "yellow" for man) from grays of corresponding brightnesses.

There are many important differences in the range of sensitivity. For example, some insects (*e.g.*, the cricket) possess special receptors called chordotonal organs which are specially sensitive to high frequencies of "sound." Many lower animals are sensitive to frequencies above the effective limits of human hearing. The hunter's dog can learn to respond to the exceedingly high-pitched tone of a special whistle, near 30,000 cycles per second, although the hunter himself can not hear it since his upper limit is near 20,000 cycles.

Insect-feeding bats offer another example. It was long thought that their astonishing ability to avoid small objects when flying in the dark was attributable to fine tactual sensitivity; however, it has been shown that the bat's remarkable aptitude for dark-flying depends upon a keen hearing of the reflections of its own supersonic (*i.e.*, above the human limit) vocal utterances from surrounding objects. When bats were released in the dark they were able to fly skilfully among numerous fine wires strung closely together; however, when the bat's ears were plugged, thus eliminating hearing, or when its mouth was fastened shut, thus stopping the high-pitched vocal sounds at their source, the skill disappeared.

In connection with acuity, or keenness of sensitivity, one striking difference in the vertebrate series is that in the most primitive vertebrates, such as sharks, olfactory sensitivity or smell tends to be a highly developed and dominant sensory field, whereas in the higher vertebrates and especially the primates, the dominant field is vision.

Data concerning sensitivity are especially useful for understanding an animal's way of life under natural conditions. For example, a mammal with keen olfactory sensitivity can track prey and tends to become a night forager, especially when vision is acute in dim light, as in the cats. In contrast, one with superior bright-light vision and less acute smell, as the diurnal monkey, ordinarily settles into a routine of daytime activity and sleep at night. Also, the facts of sensitivity are of especial use in accounting for responses in lower animals more or less limited to the tropistic type of behaviour, in which the properties of stimulation are dominant.

Sensing *v.* Perceiving.—Sensory data alone have their limitations for understanding psychological differences among animals. For example, many birds have a well-developed lens eye and a visual acuity which approaches that of man himself and exceeds that of many lower mammals such as cattle and most dogs. Yet psychologically, when the critical matter concerns using sensitivity in mastering object meanings and object relationships, birds are inferior. The status of an animal's sensory equipment is not necessarily a trustworthy guide to its psychological standing.

The resources of the organism for *perception* (*i.e.*, sensing objects in terms of meanings) is better judged in terms of how it deals with objects under varying conditions. For the reflexlike responses which feature the food-getting activities of cold-blooded vertebrates, an interpretation on the level of tropistic behaviour is justified whereas the inference of any true "food" meaning is questionable. For lower vertebrates in general, feeding is essentially a matter of what stimuli are adequate to release the unlearned lunge response; the object-organism relationship depends upon inherited sensory and nervous properties of the animal, rather than upon a special learned meaning of the object. In the full sense of the expression, this is essentially *seeing* and not *perceiving*.

Simplest Perceptual Relationships.—However, the organic

basis for meaningful-sensitivity or perceiving appears to be initiated to some extent even in lower vertebrates, as a capacity to respond to sensory change. For example, after minnows had been trained to respond by snapping at the actual movement of a small bar of light accompanied by food, the snapping response could be elicited merely by exposing the bar twice in rapid succession in closely adjacent positions. Under comparable conditions a human subject would report seeing a "movement," and that evidently was the essential effect upon the fish. The effect of "apparent movement" thus seems to be present throughout the vertebrate series. Many psychologists, and especially those adhering to a Gestalt or Configuration theory, consider such phenomena indications of an ability to "establish relationships."

What is the nature of such capacities? G. Révész trained chickens to peck grains only from the smaller of two figures, by using successively pairs of circles, triangles and arcs clearly different in size, and giving grain only with the smaller member of each pair. Then in a test two arc-figures were presented, identical in size, and both bearing free grains. The typical response of a trained hen was to peck grain from the upper figure but not the lower one. The results suggest that fowl are subject to an illusion of size similar to that of a human subject, who would see the top arc as the smaller, although objectively the two arcs are identical in size. A similar experiment with different materials was performed by W. Köhler. Chickens were first trained to peck grain only from the darker member of a pair of gray cards, then after several hundred trials of original training, new pairs of different grays were presented as tests. In nearly three-fourths of the tests the chickens pecked from the darker gray of each new pair, regardless of its absolute position in the brightness series. Correspondingly, chickens originally trained to peck from the brighter gray of a pair chose the brighter member of new test pairs. Similar results were obtained in comparable tests of a chimpanzee and a child.

These results show that throughout the vertebrate series there is present a capacity for reacting to a visual situation as a unity, in that the visual elements of the situation act reciprocally. If such an organization is termed a "relationship," it should be remembered that its unity is attributable to processes on the physiological level, rather than to more complex processes requiring intelligence.

Contrasts in Perceptual Capacity.—The perceptual limitations of lower vertebrates are suggested by results concerning the basis on which they deal with others of their own species. In the Siamese fighting fish, for example, the male responds similarly to the female and to artificial objects such as clay plugs within a given size range. If the size exceeds certain upper limits and movement is too rapid, the artifact is attacked as are other males. These findings indicate that the male's response depends upon certain discrete visual characteristics which are unlearned. H. E. Howard found that in birds such as the bunting, a mother which feeds her young regularly when they are on the nest will neglect them to the point of starvation when they are removed a short distance from the nest. Evidently the meaning of these objects for the mother bird is far from the level of what "my youngsters" conveys to a human mother. On the other hand, an experienced mother monkey can feed and protect her young in a variety of situations away from the accustomed nest.

With experience an important factor, treatment of the object becomes more versatile in dependence upon changing conditions. The first step is *sensory discrimination*—learning to distinguish and respond appropriately to simple sensory differences. Mammals, less tied to unlearned responses and better learners than lower vertebrates, excel in this capacity. Dogs learn innumerable fine odour discriminations; monkeys learn many delicate visual discriminations. In tests of weight discrimination in monkeys, the animals soon learned to pull in by its string the heavier of two visually identical boxes. The learning involved is relatively simple for a mammal; the critical matter is whether the animal can distinguish two new stimuli on the basis of a given characteristic such as auditory pitch, or visual brightness.

The next stage involves the mastery of a *schema*, or pattern of sensory cues, to the extent that giving a response may depend upon special conditions such as the presence or absence of certain parts of the pattern. At first a young hunting dog may turn to follow almost any animal scent; later, if properly trained, he will track only partridge and only if the scent is fresh. This type of accomplishment, which has been called *conditional discrimination*, places far greater demands upon learning ability than does simple discrimination, and unless very simple lies beyond the capacities of lower mammals.

Appropriate response to the perceptual schema becomes more difficult when it is encountered in a variety of situations, accompanied by variations which initially disturb the animal. For example, not all pet dogs can learn that a walk is forthcoming only when the master wears his hat, rather than when he merely stands near the door holding the leash. A control over the essential significance of the schema despite the presence of various confusing meanings under different conditions, marks the mastery of a more complex set of relationships frequently termed an *abstraction*. As an elementary instance, white rats after hundreds of trials become able to jump to a three-cornered figure ("triangle") in any position into which it is tilted, and avoid a circle; whereas the chick is lost, after learning to discriminate these two figures, if the specific learned position of the "triangle" is changed.

Discerning a given pattern in varying circumstances, amid confusing differences and partially similar features, is an accomplishment in learning relationships of which only the higher mammals are clearly capable. The limit of the lower mammal for "abstraction" is soon reached. In contrast (as N. Kohts has shown with her matching-from-sample technique) the chimpanzee is far more versatile, and can single out the given schema (*e.g.*, "triangle") although it is presented in different sizes and colours and among other figures similar to it in colour and size.

Very different attitudes have been taken toward the subject of perception in comparative psychology. To those who find in lower animals a mind analogous to human consciousness it seems desirable to attempt an inference from behaviour of the animal's consciousness of its environment. On the other hand, modern experimentation has strengthened the tendency to describe the perceptual capacities of different animals in terms of how they can deal with objects under different conditions. Analogies from human consciousness are often criticized as vague because they are not readily checked against fact, and because they are strongly influenced by the simplest aspects of sensitivity. The key matter for perception is not the presence or absence of given features of sensitivity (such as colour vision), but rather, the given animal's ability to organize sensory data in dealing appropriately with new situations. This is critically dependent upon its resources for learning new adjustments.

THE LEARNING CAPACITY

If lower animals are superior in their fund of activities influenced by hereditary equipment, this is more than balanced by the capacity of mammals for acquiring new behaviour through learning. E. Hering and others have viewed memory as a general property of all protoplasm, in that the action of a stimulus upon organic matter always leaves some physiological changes which may influence further responses to stimulation. In this sense "memory" would include even the simplest types of trace effect and behaviour changes such as those in plants and Protozoa. Such changes are comparable with those termed *hysteresis* in physical objects—for example, a temporary change in electrical conductivity through the action of a single charge upon a metal bar. However, in the comparative psychology of learning, the fact of primary importance is not the mere presence in the organism of some trace-effect of stimulation, but what class of trace is involved as indicated by its contribution to the organization of individual behaviour. The problem then becomes one of studying the change in organization in relation to the animal's environmental adjustments. Learning to turn right may be termed a *habit*, whether it appears in earthworm or in man, in the sense that in both cases a learned activity is involved; yet the manner of learning and the significance of the act for further behaviour is certain

to differ radically in the two cases. To understand the nature of learning it is necessary to study such differences among various animals.

The Varieties of Learning.—*Adaptation and Fatigue Phenomena.*—The simplest type of "trace" phenomenon is one based upon processes akin to sensory adaptation or muscular fatigue. If a child has become dark-adapted by staying in dim light for a time, as long as given chemical changes persist in the rod-cells of its eye it will see poorly in bright light and collide with objects. A dog which has just run a long distance scratches himself weakly, because of fatigue changes (*e.g.*, lactic acid in muscles) which temporarily impair muscular contraction. Similar instances based upon adaptation or fatigue are identifiable throughout the animal series from Protozoa to man. They are not generally classed as instances of learning, for these reasons in particular: they are really only local in their scope, survive only for limited times, and do not affect the typical behaviour of the individual in any extensive or relatively lasting way.

It is otherwise with many instances of negative adaptation, in which given stimuli in the course of time cease to have their initial effect. A snail in an aquarium continues to feed and does not contract as at first when it is jostled by a passing fish; a trained draft horse becomes accustomed to wearing his harness without disturbance; a clerk becomes able to work in a noisy office. Such cases involve more thoroughgoing and lasting changes in behaviour than is possible through simple local trace effects such as those underlying fatigue and sensory adaptation. Very probably they are closely related to simple conditioned-response learning.

Conditioned Responses.—Conditioned-response learning is found at the lowest point in the animal series where learning has been dependably demonstrated—in the flatworms. It has been described as the simplest form of learning, in that the essential result of the conditioning process is a new stimulus-response connection, and the nature of what is learned depends upon what given stimuli play repeatedly upon the animal. That is, the experimenter or animal trainer, by his selection of a given pair of stimuli, determines what new behaviour is to be acquired. The procedure is simple: on each trial an original or "unconditioned" stimulus, selected because it elicits the critical reflex or other response at the outset, is presented with a new or "conditioned" stimulus which does not at first produce this response. By pairing these stimuli repeatedly, the new stimulus finally is made a controlling (*i.e.*, fully conditioned) stimulus, in that it now elicits the critical response in the absence of the original stimulus. In the classical experiment of I. P. Pavlov with dogs, meat-powder-in-mouth was the unconditioned stimulus, secretion of saliva the critical response aroused by it, and a bell-sound the conditioned or new stimulus which finally came to elicit salivation through repeated combination with the meat powder. (Fig. 2.)

It is probable that almost any given response, reflex or learned, may be conditioned if the necessary stimuli are appropriately paired. Although at first a dog scratches only in response to local irritation of the skin (*e.g.*, from a flea bite, or a mild electrical shock) the appropriate pairing of this original stimulus with the snapping of fingers, the sight of a whip, or the smell of perfume, will condition the critical scratching reflex to the given new stimulus. In higher animals, and especially in the mammals, additional features of the situation beside the focalized new stimulus typically gain some importance for conditioning. In Pavlov's experiment, for instance, both the general appearance of the customary room and the tactual effect of the experimental harness were of importance as secondary conditioned stimuli, as was shown both by occasional responses to such stimuli alone, and by the reduction of salivary response to a given conditioned stimulus (*e.g.*, a buzzer-sound) when the animal was tested in a new room without his harness. In this way features of the situation which are regarded as incidental or are overlooked by the experimenter may become critically important, as in the case of the "counting horse," which had somehow become conditioned to start and to stop tapping according to slight movements of persons nearby.

Conditioned responses are not the same wherever found in the animal series, but vary in their degree of complexity and their relation to other behaviour. For this the learning capacity of the given animal is critical. In the invertebrates capable of conditioned learning and in lower vertebrates, conditioning is held largely to combining reflex or forced responses with elementary (*i.e.*, uncomplicated) stimuli. In mammals, there appear wider possibilities of conditioning learned responses to more complex stimuli, and we may speak of systems of conditioned responses. The importance and prevalence of such learning is illustrated by many routine (but learned) acts in food-getting, evading customary disturbances, and other everyday practices of domesticated and pet animals. The milkman's horse with its ability to start or stop according to given special footstep-and-bottle sounds may be offered as an example.

In mammals there appears more and more prominently an ability to modify conditioned responses according to prevailing conditions. For example, in conditioning a dog to bell-sound (new) coupled with a shock to one leg which elicits reflex flexion (pulling back) of that leg, not only does the bell-sound alone presently cause the given leg to pull back without the electrical shock, but other changes appear. It is noticed especially that, as training continues, the leg gradually flexes less and less, until finally it lifts just enough to clear the paw from the shock. The learned modification of conditioned responses according to their consequences (*i.e.*, food, or removal of an irritating stimulus) actually represents the merging of *conditioned*-learning with *selective* learning, to be discussed below. Such elaborations of conditioning become possible in higher mammals, particularly in dependence upon their superior nervous equipment, as experimentation has shown. For example, the above experiment leads to skilful paw-withdrawal only in normal dogs. When the cerebral cortex of the brain was removed by operation in certain dogs, later, even after hundreds of trials, no conditioned learning was possible beyond general excitement and random leg flexion when the bell sounded. In contrast to the skilful response of one paw in normal dogs, the shortcomings of conditioning in mammals without brain cortex resemble the limitations of lower vertebrates and invertebrates.

Trial-and-Error or Selective Learning.—This form of learning, which reaches its peak in the highest mammals, has not been clearly demonstrated below the arthropods. It may be illustrated by the behaviour of a hungry dog outside a food-box which can be opened only by pulling a cord which hangs on one side of the box. If such problems are quite new to the dog, his first responses are highly variable. He does nearly everything which is possible for him to do under the conditions. He paws at the bars and squeezes his nose between them, paws and scratches at the ground near the box, at intervals runs around the box, then presently sits and howls. At length the cord is pulled by chance, in the course of random biting or pawing at objects, and the dog enters the open door when he sees it, to the food. The first trial typically is very long; however, as E. L. Thorndike first reported from experiments with cats and other mammals, further trials involve decreasing amounts of random activity and hence less time is required to pull the cord. Because of these characteristics the name "trial and error" is frequently applied to such learning. The first change to appear is that more and more time is spent working in the general vicinity of the cord; gradually superfluous activities drop out until finally the dog pulls the cord as soon as he is introduced into the situation, and directly enters to the food. The animal has mastered a habit which, through what is called *selective learning*, an organization of appropriate responses remains from his initial random behaviour.

Many kinds of problem-box situations have been used in studying selective learning, from types in which the animal's escape or his entrance to food depends upon pressing a pedal, unfastening a latch, or working a lever, to elaborate combinations of these and other difficulties. Higher mammals such as the monkey master problems (*e.g.*, a combination of latches) which are insoluble for the lower forms, not merely because of superior manipulative ability, but especially because of a superior capacity for organization in learning. Birds, in contrast to mammals, not only seem

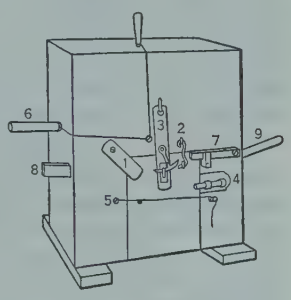
PRIMATE BEHAVIOUR STUDIES WITH CHIMPANZEES

1. Köhler's chimpanzee Sultan making a single stick-tool of two sticks, each too short to reach distant food through a wire fence
2. Not humour, but a temper tantrum
3. Mrs. Kohts pretends distress; the chimpanzee appears to be sympathizing

to learn more slowly, but also acquire an inferior mastery of the problem. For example, they may be taught to press a horizontal string to open the door of a box; but if this string is moved to another place on the box after the habit is learned, birds tend to work in the place where the string hung at first instead of shifting their efforts to the string in its new position, as most dogs would. Inferiority of the lower vertebrates in selective learning appears especially as an inability to master relationship between the critical act (string-pulling), the object acted upon (the string) and the end result (getting food).

An instrument much employed in the study of selective learning is the maze or labyrinth, in which the presence of blind alleys affords a special means of studying the elimination of errors. A variety of animals has been tested, from the crab to the chimpanzee and man, in maze patterns of many types and degrees of difficulty. Some of the differences are striking. For instance, to learn a simple maze with only one blind alley the crayfish *Cambarus* required at least 60 trials; whereas ants of the *Formica* (mound-building) species have learned mazes containing six blind alleys within 35 trials, and white rats required 12 trials or less to master the same pattern (enlarged to scale).



FROM KINNAMAN IN "AMERICAN JOURNAL OF PSYCHOLOGY," VOL. 13, P. 112 (1902)

FIG. 3.—KINNAMAN'S COMBINATION PUZZLE BOX FOR TESTING MONKEYS. NUMBERS INDICATE THE REQUIRED SEQUENCE OF MANIPULATING ITEMS FOR SOLUTION OF PROBLEM

More significant than the number of trials required is the fact that inframammalian animals learn in a different and inferior way as compared with mammals. In the maze-learning of ants and birds, for example, not only do particular errors tend to persist much longer than in the rat, but avoidance of individual blind alleys progresses much as though these were independent problems. For the rat, learning to avoid different blind alleys is interdependent. The rat's organization of the maze habit ranks well above the way in which inframammalian animals learn; and consequently the rat excels greatly in further tests of the habit. It readily learns to reverse the direction of its learned turn where a given blind alley has been opened and its previously correct alternative closed; it readily learns to make use of new short-cuts which are opened in mastered mazes. The ability to use acquired behaviour in new situations is a particular mark of the mammal's superior capacity for organizing trial-and-error learning.

Space does not permit a theoretical discussion of selective learning, except for certain general remarks on the question of error-elimination. It was formerly thought that a simple punishment-reward theory was adequate, based on the assumption that punishment "stamps out" wrong acts while reward "stamps in" correct acts. Research has shown that, notwithstanding the importance of incentives and motivation in selective learning, this idea is over-simple and misleading. The fact seems to be that punishment and reward as such do not have any necessary automatic effects upon the nervous processes underlying learning. Known functions of the reward or punishment are to emphasize particular features of the situation, and to elicit given responses (*e.g.*, approach to a reward). Thus punishment is advisedly used only in mild forms, to elicit avoidance responses to certain parts of the situation (*e.g.*, to keep the animal on its stool in circus training), or to emphasize certain features. Strong punishment is inadvisable, for it opposes learning by calling out avoidance responses to the entire situation, including the trainer in the case of higher mammals.

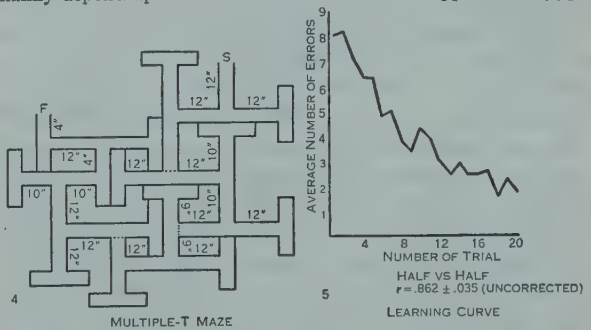
The Problem of Abridged Learning.—It is difficult to interpret a given act correctly unless its background is known. Once when C. Lloyd Morgan had been trying to teach a fox terrier to pull a crooked stick through a fence, unsuccessfully because the dog persisted in pulling the stick so that the crook caught between the fence palings, a passerby arrived just as the dog accidentally caught the crook itself and with a wrench broke it off. Having seen no more than a small part of the entire performance, he remarked, "Clever dog that, sir; he knows where the hitch do lie." The correction of this error, a typical result of superficial observation, is not to say that all solutions in all animals are limited to a laborious learning process. For the given animal may have hit upon the "correct solution" accidentally (as was true in this instance), may have mastered it through a gradual selective-learning process, or may have attained it through a superior short-cut process of which anthropoids (*see* PRIMATES) in particular are capable. The latter type of abridged solution is frequently called "insight."

Our interpretation of selective learning must be revised for mammals when the test situation itself is not entirely new. In this case the animal is less excited and behaves less erratically than in a strange situation; furthermore, the new solution is hit upon sooner because previous learning is influential. As was suggested above in the discussion of perception, it is characteristic of mammals and particularly of primates that habits such as a given pedal-pressing act may be applied in new situations, combined with different amounts of variable activity depending upon the animal and the newness of the problem. The higher mammal appears "to get the point of the problem" more readily, to have more "insight," the greater its previous experience in similar problem situations.

The ability to apply previous learning to shorten the solution of further problems is complex in mammals because of such short-cuts, but relatively simple in lower vertebrates because the capacity for short-cut solutions is virtually absent. Calling a more efficient type of solution "insight" does not explain it; actually, the term is descriptive since it merely emphasizes the presence of a "seeing into" the problem. It suggests a superior kind of organizing ability which is qualitatively superior to that of regular selective learning.

THE PROBLEM OF INTELLIGENT BEHAVIOUR

Intelligent behaviour is defined especially in terms of the animal's capacity for new appropriate modes of adaptation in problem situations. From this category, types of response which mainly depend upon unlearned factors for their appearance (typi-



FROM TOLMAN AND NYSWANDER IN "JOURNAL OF COMPARATIVE PSYCHOLOGY"

FIG. 4.—MULTIPLE-T ALLEY MAZE FOR TESTING RATS. S. STARTING ALLEY; F. POSITION OF FOOD BOX. FIG. 5.—AVERAGE ERROR RECORD FOR 25 RATS LEARNING THE ABOVE ALLEY-MAZE SITUATION

fied by insect adjustments) must be excluded, however adaptive they may be. Furthermore, although intelligent behaviour depends to some extent upon the readiness with which the organism may be conditioned, and more so upon its capacity for selective learning, these are not the most important criteria of "intelligence." Most critical is the animal's capacity for the special short-cut types of adjustment referred to above as "insight," frequently termed "higher mental processes." These necessitate a better command over the special relationships of objects and events than can be attained simply through learning.

Typical "Insight" Solutions in Primates.—The pioneer work of L. Hobhouse, M. Haggerty and others early in the 20th century indicated that the monkey solves various types of problems with greater facility than would be expected through selec-

tive learning alone. For example, in one of Haggerty's problems with monkeys, the subject had to climb the side of a cage and thrust a hand from below into an inclined chute to obtain fruit. After watching another individual solve the problem four times, one animal worked rather directly around the chute and soon had pulled the string in a manner suggesting that, as one would say for a human subject under similar circumstances, "he caught the point" of the problem sooner than he could have acquired it through selective learning. Later, especially in the work of R. M. Yerkes and W. Köhler, similar abilities were demonstrated in the chimpanzee in a higher state of development than in monkeys.

In the experiments of Yerkes and Köhler, chimpanzees were presented with problem situations such as food suspended high above the ground or placed beyond a fence, where it could not be attained by ordinary direct responses such as reaching or jumping, but required some special mode of capture. Although there were many failures and some animals never succeeded very well, the records were replete with instances in which chimpanzees had hauled in food by reaching out with a stick through the wire, or had attained suspended food by means such as stacking boxes or vaulting from a pole. In one of Köhler's tests a chimpanzee which had previously used single sticks only was given a problem in which food lying beyond the wire could be reached only by combining two short hollow bamboo rods. First there appeared inappropriate responses, such as simply reaching out with the arm alone, using the sticks singly, or using one bamboo piece to push the other toward the food. Such behaviour indicates that, although he is not working very appropriately, the animal is employing foreign objects as a means toward the end of obtaining the food—in other words he is using tools. At the end of an hour in this case, the result was apparent failure, since at that point the animal sat with his back to the food, idly handling the sticks. Somehow in this activity a critical change appeared, as follows:

> Sultan first of all squats indifferently on the box, which has been left standing a little back from the railings; then he gets up, picks up the two sticks, sits down again on the box and plays carelessly with them. While doing this, it happens that he finds himself holding one rod in either hand in such a way that they lie in a straight line; he pushes the thinner one a little way into the opening of the thicker, jumps up and is already on the run toward the railings, to which he has up to now half turned his back, and begins to draw a banana towards him with the double stick. (From W. Köhler, *The Mentality of Apes*, Harcourt Brace.)

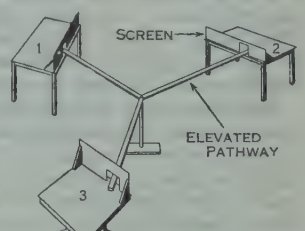
That the combined sticks were perceived and used as a true tool and not used simply by accident, was indicated by the fact that when the sticks became separated, the animal straightway reconnected them in a manner that suggested an understanding of their function together. (Pl. fig. 1.)

"Representation" as a Factor in Reasoning.—The solution processes of chimpanzees often resemble in simpler outline those characteristic of man when he is said to be reasoning. Animal psychologists have studied the lower-animal process in the attempt to find what is most essential to it. One approach, arising from early efforts to test the presence of ideas, is the *delayed-response* method. In its original form, after the animal had learned to go to food through whichever one of four adjacent doors was lighted, special tests were made. In each of these delay tests, the subject was first presented with a light over one of the doors, then after a given interval of time had to find the correct door without the distinguishing light. With primates, the animal was shown food under one of several cups, or saw food buried in one or more places, and after a delay he was permitted to show whether he could go directly to the hidden food.

Although the outcome differs according to procedure and situation, the general result of such experiments is that lower mammals such as the rat require a longer preparatory training, and are more likely to require keeping a given bodily orientation during certain kinds of tests, than are primates. In these tests, monkeys and chimpanzees can delay successfully over intervals of 24 hours or even longer. The general interpretation is that primates owe their superiority to a better ability to *represent* the absent object. That is, in some way the adjustment to the food in a given position is symbolized, so that it can be recalled after the interval of delay. This ability to hold the correct act over an interval is often interpreted as centring around an abbreviated form of the actual adjustment—lifting a box, for instance, might be represented by processes involving a slight tensing of arm muscles as when actually raising a box. According to this view, in comparison with man's great advantage of being able to represent absent things verbally, lower mammals are handicapped by the necessity of representing their adjustments in much less specialized ways.

In lower primates there is evidence for a fairly well-developed capacity for anticipating or dealing with *particular* absent objects. For example, in a delayed-response experiment with monkeys, in which a banana was given on some trials and lettuce (less preferred) on other trials, the subject became emotional and refused to take the lettuce if he had seen a banana concealed before the delay. Evidently the animal specifically anticipated a banana on such trials, for lettuce was taken readily in delay trials which were preceded by the showing of lettuce.

The ability to represent objects which are not immediately present is important for insightful problem solutions. This is suggested by instances such as that in which a chimpanzee, after having worked at a suspended-food problem for some time without success, suddenly turned after a jump and rushed around the corner of a building, returning with a box which he had often seen in that place. Although this ability certainly contributes to the possibility of short-cut solutions, it alone can not account for their occurrence. In particular, it does not account for their *newness;* for the mere recall of represented objects would be a duplicate of the original experience. In the higher primates, particularly, the newness of possible solutions is much more striking than in other mammals.



ADAPTED FROM MAIER & SCHNEIRLA, "PRINCIPLES OF ANIMAL PSYCHOLOGY" (MCGRAW-HILL BOOK CO., 1935)

FIG. 6.—MAIER THREE-PATH SITUATION FOR TESTING "REASONING" IN THE RAT. AFTER THE ANIMAL IS TRAINED TO RUN EVERYWHERE ON THE APPARATUS, WITHOUT FEEDING, SPECIAL TESTS ARE RUN. IN EACH TEST, AFTER A BRIEF FEEDING ON ANY ONE TABLE (E.G., 3), THE ANIMAL MUST FIND HIS WAY BACK FROM EITHER ONE OF THE OTHER TWO TABLES (E.G., 2 OR 1)

Testing Freedom from Stereotyped Learning.—That mammals differ considerably in their ability to discard specific learned behaviour when changes are required, was demonstrated by G. V. Hamilton. The subject, a mammal, was presented with four doors. Only one of the doors was open on a given trial, and this one was never the door open on the last trial. Only human subjects were able to discover this fact; but none of the monkeys, which often tried all four doors in succession on each trial, often without trying any one door repeatedly or neglecting any one door very long. The last type of behaviour, termed a *stereotyped habit* (because it is persistently repeated in a fixed, unchanging way), was most frequent in dogs, cats and horses,—especially in the horse. It is significant that making stereotyped responses, and persistently repeating errors, is a marked characteristic of behaviour in mammals from which roughly one-fifth or more of the cerebral cortex has been removed by operation. Such partially decerebrated animals are inferior to normal individuals on insight problems, much as the horse and other lower mammals are normally very inferior to primates on such problems.

This situation was adapted by Yerkes to the further investigation of plastic behaviour, in his *multiple-choice tests.* The animal was presented with a series of nine doors, with a row of five doors open on each trial, but always a different set of doors (to eliminate simple position learning). Food was to be found behind just one of the doors on each trial, and the subject's problem was to discover that the correct door was systematically related to the others in position. Sample problems were (1) always first at the right; (2) always second from the left; (3) middle door. Theoretically, the experimenter's aim here is to compare the level of intelligence of different animals, by starting with simple settings and increasing the difficulty until failure appears. Thus, in the

above problems starting with (1) as presumably the simplest, both the crow and the white rat solve (1) but fail (2); problem (3) was failed by the pig, but was solved by monkeys. The chimpanzee solves even more complex settings. With settings more difficult than (3), it is possible that success typically comes through an "abstraction" type of solution involving a mastery of relationships among the settings, or what Yerkes calls "ideational processes." To the claim of its advocates that the multiple-choice method affords a means of testing the comparative intelligence of animals, its critics object that the manner in which the method discloses the nature of ideational processes is not clear. Then too, the nature of this problem set-up seems to admit, for certain animals more than for others, the influence of factors opposing the use of intelligence. For example, multiple-choice problems solved with relative ease by chimpanzees were failed by orangutans because the latter tended to persist in wrong responses—possibly because of hampering emotional reactions rather than because of an intelligence below that of chimpanzees.

Relative Capacity for Indirect Solutions.—Many of the special problem-solutions described, even for mammals below primates, resemble the type which in man is recognizable as "perception of relations" or understanding. Numerous types of results indicate that mammals below primates are definitely inferior in this respect. The cat can learn to manipulate a lever, but neither cat nor dog can assemble or use a true tool as can many chimpanzees. Box-stacking in the chimpanzee may be considered a simple form of tool-construction, as may combining sticks to make a single long food-rake. Köhler emphasized the far greater ease with which primates correct their original direct responses to food and substitute more appropriate indirect ones. A hen when separated from food by a wire fence continues for a long time to rush about in zigzag manner close to the food, whereas going around the end of the fence to the food appears more readily in the dog, and far more readily in the monkey. Even when a roundabout route has been learned, the sight of food frequently holds the rat, cat or dog to the spot and prevents using the detour. The greater ease with which the chimpanzee can move away from the goal to reach it indicates a much better mastery of the relationship between its own position, the barrier and the goal. Its superiority to the monkey in this respect is indicated by the chimpanzee's frequent success and the monkey's failure in problems which require a subject to first push food away from him around a barrier before he can draw it in all of the way.

Reasoning as Reorganized Learning.—A feature of short-cut or "insightful" solutions frequently used to distinguish them from the more laborious and gradual solutions reached through selective learning is that the former type of solution often appears suddenly, after a period of apparently fruitless trial-and-error work. *Suddenness* in the appearance of the solution or of new attempts at a solution is especially notable in the performance of higher primates such as chimpanzees, less prominent in monkeys. This frequent abruptness with which the eventual solution comes should not be taken to mean that it occurs independently of previous learning and without more or less random and variable activity in the problem situation.

A useful conception of suddenly-appearing solutions is that they are the result of a completed reorganization of two or more patterns of response which have become available as a result of previous experience in the same problem situation or similar situations. For a time these may exist as relatively unitary adjustments, such as jumping to food and handling a box, which may be used together as one pattern more or less suddenly following numerous activities involving them separately in the food situation. N. R. Maier has offered a demonstration of this type of solution in a simple form in the rat. The animal is first trained to run from one table to another on the 3-way apparatus shown in figure 6, making the runs between each two tables with equal frequency and without feeding. Then in the test, the rat is first fed on a given table (*e.g.*, No. 3), after which he is carried to one of the other two tables (*e.g.*, 1). Purely on the basis of repeating learned responses, the rat in this case would turn with equal frequency to tables 2 and 3; however, the fact is that adult rats are able to return to the one food-table which is correct on the given trial with at least 80% success. The appearance of correct solutions, when a direct recall of learned responses would give chance scores, indicates a capacity for reorganizing items of learning which have been separate in previous experience. A more complex instance of such reorganization, not possible in mammals below primates, would be using a pole to poke food from a hollow cylinder, although previously sticks have been used only in general play and only the arm has been used in drawing out food from tubes. Maier has pointed out the qualitative similarity of such problem-reorganizations to reasoning in man.

MAN COMPARED WITH THE LOWER ANIMALS

Although man is not the most highly evolved animal in all organic respects, his psychological superiority can not be disputed. This must not be considered an absolute superiority, however, for most of man's mental advantages are also shared, although to a lesser extent, by his mammalian relatives.

Reasoning and Foresight.—Although reasoning as an identifiable ability is present widely among the mammals instead of being restricted to man as was once thought, it is limited in the lower mammals to a simpler form and plays a much smaller part in everyday adjustments than in man. Just as the novel use of past learning shows a greater influence upon the activities of great apes than of lower mammals, it is far more prominent in man than in his primate relatives.

One of man's particular advantages is his superior ability to demonstrate foresight, to reason with reference to a problem which will arise in actuality only at a relatively future time. "Time" for the lower animal is largely a matter of the present, and to relatively different extents, the past. The responses of lower animals may be conditioned to recurrent events, on the basis of rhythmic internal processes such as those of digestion, or particular external stimuli characteristic of a particular time of day or of given daily events. The discrimination of short intervals of time in terms of action has been demonstrated in lower animals such as rodents. Delayed-response tests show that their anticipations are also held to fairly short times and to a low level of complexity. Even in the apes the anticipation of future events and reasoning about them is characteristically restricted to specific occurrences of familiar types expected to recur in the relatively near future. The capacity to reason systematically forward to events over relatively long intervals of time requires a greater capacity for reorganizing past experience than is found in any animal below man.

Another way of putting it is that man can utilize his reasoning capacity to plan—that is, to combine and appropriately rearrange whole systems and sequences of reasoned and learned processes with reference to some goal which he expects to reach in the more or less distant future. In the chimpanzee, the simplicity of foresight is illustrated by food-expectancy, revealed in the disturbance shown when less preferred food is substituted for the originally exposed lure during a delay interval of a few hours. If the ape is capable of reasoning in the present to forestall a difficulty expected to arise in the distant future, the ability remains to be demonstrated.

Planning for future needs or future security usually requires not only foresight but also the use of reasoning in what may be called reflective thought. This is illustrated by a man reasoning about his own condition as he observes it in the present or expects to find it in the future, in relation to surrounding conditions present or anticipated. Differentiating and identifying the self in thinking, marked by the first effective use of personal pronouns such as "me" at about two years of age, is an important epoch in the development of human reasoning. This ability is on a far higher level than is an animal's merely reacting emotionally in a direct manner to phases of its own behaviour or appearance, as might a strutting male pigeon or a growling dog prepared to fight. The ability for personally redirected thought is a taking note of one's own condition in relation to the condition of other persons or objects, and through reasoning arriving at appropriate new procedures. This more elaborate type of involuted reasoning is an expression of the superiority in intelligent behaviour which

admits foresight. The fact that all men at times use this capacity poorly, and that some men never appear to use it, does not alter the strength of the comparison.

Spoken Language and Communication.—The process of communication, although frequently confused with the use of a language, must be distinguished from it as much simpler. Communication is involved whenever the behaviour of one individual influences others; whereas a true language exists only when an individual utilizes a special code or system of symbolic activities with the expectation of influencing the conduct of companions in given ways. The simplest type of communication is that in which the behaviour of one individual excites others incidentally through auxiliary effects such as chemicals exuded (*e.g.*, the reflex opening of an excited bee's scent gland) or through special tactual effects as when a termite colony is aroused by the head-rapping of excited individuals on gallery walls. From the category of true language we must also exclude the great variety of sounds and movements which throughout a large part of the animal series influences behaviour in activities such as mating. Effects such as the flashing of fireflies, the chirping of crickets, and the mating colorations, movements and sounds of mature males in many vertebrates from fishes to mammals, all are to be considered relatively incidental products of organically-excited behaviour to which species companions respond on an unlearned basis.

A step is taken toward language when the appropriate responses are learned or conditioned, as often happens in social groups of birds and mammals when the excited cries of one startled individual throw others into flight. Beyond that a very simple symbolism, that is, a learned special cue controlling another's behaviour, appears in mammals when activities which are at first mere accompaniments of emotional excitement (*e.g.*, barking and biting in a dog) appear in a reduced form after merely beginning the act has repeatedly produced flight or some other characteristic reaction in another. Thus, in time a dog learns to "threaten" merely by baring his fangs. Instances of such simple, discrete language activities are not uncommon in the everyday life of domesticated mammals, as for example the "begging" of a hungry dog and the mewing of a shut-in cat before a closed door.

Although primates below man seem to lack any system of symbols which can be termed a true language, on the basis of his extensive experience with chimpanzees Yerkes pointed out that—"Yet combined, the varied signs which are commonly observed serve to keep the animals in effective touch, well informed about one another's presence and attitude, and also about especially significant features of their environment." (From R. M. Yerkes and A. W. Yerkes, *The Great Apes*, Yale Univ. press.) In the chimpanzee one observes a great variety of sounds and movements which specifically influence others in given ways, although they appear more often as incidental features of the first animal's excitement (*e.g.*, the "hunger cry") than as "intentional" means of producing given acts in others. Yet it is well established that the chimpanzee is capable of learning to use gestures as special signs to initiate given behaviour in his companions, as when one taps the shoulder of a lagging companion in a laboratory task, or extends a hand to a new and partially accepted individual.

The general psychological superiority of man is emphasized by his capacity for a systematic code of language symbols. The breadth of this code for expressing meanings is apparent in the fact that its symbols are essentially nonmimetic; that is, the symbol itself (a word or number) is unlike the represented acts or objects. In contrast, the limited language activities of lower mammals are essentially mimetic, in that the symbol or sign is a part of the represented activity which has come to represent the whole. Even the chimpanzee, perhaps the best candidate for verbal language among lower animals by virtue of its linguistic accomplishments together with intelligence, somehow falls short of attaining such a language. Many experimental attempts have been made to teach chimpanzees true vocal-language symbols, without success. The explanation can not lie in a defective process of sound-production, for apes have a surprisingly varied vocal repertoire. The parrot is noted for its ability to learn an exact reproduction of frequently heard sound patterns; however, its utterances are to be considered skilled acts essentially devoid of any meaningful association with the objects or situations which may call them forth.

Factors Underlying Man's Mental Ascendancy.—Apparently, the mastery of verbal symbols even as separate signs calls for a building up of object-meanings and object-relationships which exceeds the resources of chimpanzee intelligence. Chimpanzee symbolic processes, although superior to those of other mammals, are rudimentary and lacking in versatility as compared with those of man. Although the chimpanzee can be taught to ride a bicycle, to use table utensils, and to mimic many particular human activities, the lengthy training process required shows that the uses of human objects are bound more particularly to given sensory properties and to given routines much more rigidly than in the older human child. The chimpanzee learns to use certain vehicles without being able to learn a single abstract symbol (the sound "ride") for the act as does the child, for he never succeeds in really mastering the general properties which different vehicles have in common. Investigation shows that at first the symbols of the human child are similarly limited by centring around particular situations and concrete uses; yet children advance to higher stages, while chimpanzees largely remain on the lower level.

Although some chimpanzees are able to reason out simple tool-using solutions, for the most part they combine objects into new unitary (and utilizable) forms only in crude and rudimentary ways. Their perceptual shortcomings, *i.e.*, their limitations in dealing with object-relations in organized meaningful ways, evidently prevent chimpanzees from interrelating numerous discrete solutions to form *tool principles* which might lead to the creation of more and increasingly improved new tools. Deficient in mastering single symbol-action patterns, the chimpanzee can not arrive at the use of symbols in serial patterns (*i.e.*, in word sentences) to express the interrelationships of varied experiences. Thus his episodes of reasoning are relatively isolated and discontinuous, and he seems incapable of passing on the results of any but the simplest and most routine experiences (*e.g.*, nest-building; parental guidance in locomotion) to further generations as tradition or social heritage.

Even so, the psychological difference between ape and man must be regarded on the whole as relative rather than absolute. This fact is brought home by the superiority of chimpanzee to monkey in functions which may be crudely designated as perception, response to training and memory, general adaptiveness and co-operativeness in new situations in which the chimpanzee stands well below man.

The psychological deficiencies of the chimpanzee as compared with man, and the monkey as compared with the chimpanzee, appear to be imposed particularly by the lesser development and elaboration of cerebral cortex in the lower primates. In the series: rat-dog-monkey-chimpanzee-man, not only is there a progressive increase in the proportion of cortex to body weight, but there is an increase in the number of cells and the complexity of the cortical ganglionic layers. Such increases in anatomical resources parallel an improvement in the capacity for complex functions centring around learning and the reorganization of learning. The validity of this relationship is supported especially by K. S. Lashley's discovery of a high positive correlation between the amount of intact cortex in rats and their performance in learning mazes of differing complexity, and N. R. Maier's finding that the loss of approximately 20% of cerebral cortex abruptly reduced to a low point scores made by rats in a simple reasoning test. That symbolic behaviour and the degree of its development is limited by the adequacy of cerebral correlation function, is emphasized for man by the low attainments of imbeciles in learning even the simplest word meanings, and by the progressive breakdown of symbolic verbal functions with advancing pathological degeneration of cortical tissue occurring in diseases such as paresis. The patient in such disorders becomes steadily more deficient in his ability to define and use words, and may finally reach a stage at which he sees once familiar objects without being able either to name them or recall their meanings.

Contrasts in Emotion.—Those organically aroused states

characterized by experiences of unpleasantness and pleasantness, and ordinarily spoken of as emotions, constitute perhaps the closest psychological relationship between man and lower animals. The experiments of W. Cannon in particular have shown that similar physiological changes such as impeded digestion, release of adrenin, and increased heartbeat occur in connection with strong emotional excitement in lower mammals such as the dog and cat much as in man. Similarly, more placid emotional conditions are characterized by organic changes such as facilitated digestion and slower heartbeat. Thus in what may be called the organic basis, the emotional lives of man and lower animals seem to have much in common.

Fundamentally, there is a close relationship between the outer cause of excitement and the nature of emotionalized response. In higher and lower animals alike, what may be called the strong emotions characterized by *interruptive* visceral changes such as impeded digestion, and impulsive or reflex external responses such as flight or fighting, are aroused by intense stimulation or sudden changes in stimulation. Conversely, gentle repeated stimulation calls out *vegetative* internal changes such as the facilitation of digestion, with the unlearned response of many invertebrate and lower vertebrate animals an approach of the entire organism toward the source of stimulation. In very young mammals the typical unlearned response to weak stimulation appears to be a reflex extension of the stimulated limb. Thus, primitively, the accompanying external behaviour occurs as a reflex, impulsive part of the general state of excitement. The evolutionary significance of the connection is clear; it is highly adaptive to be what Cannon has called on a "war footing" (*i.e.*, reflexly prepared) in the presence of strong stimulation and (whether the animal is capable of perceiving it or not) probable danger.

Because of the similarities in the external and internal aspects of emotional response in man and lower animals, analogies from human consciousness are tempting, such as inferring an experience of pleasantness when the emotional reaction involves approach or acceptance of an object and unpleasantness in cases involving withdrawal. This procedure calls for caution, however, in view of the fact that in the simpler animals the relationship between internal changes and external behaviour is fundamentally reflexive and unlearned. There is little to be gained in discussing whether the fish or octopus experiences "fear" in the human sense in its excited flight from the location of a large, suddenly-moved object, or whether ants licking their queen and a human mother patting her infant experience "love" in the same sense. The presence of radical perceptual differences, for one thing, makes the analogy questionable.

The most significant similarities to human emotional patterns appear, of course, in the other primates and especially in the chimpanzee, whose temperamental resemblance to man seems much closer than does his intellectual resemblance. Practiced observers recognize patterns meriting terms such as confidence, discouragement, annoyance, jealousy, friendliness or suspicion, and many others, appearing under comparable conditions in the ape and the young human child. These patterns are marked by varieties of external signs of emotionality, some of which are roughly similar in ape and child—including variable facial expressions; limb, head and body movements; and changes of tension. These may be described as crude similarities in emotional attitude toward the object or situation. The chimpanzee's whole body is involved as a rule, as in stamping and shrieking in rejecting something or approaching and attempting to pat or groom an accepted person, and in this sense it may be termed much more "dominated emotionally" than adult man.

Experiment shows that in the higher animals emotional responses become transferred to objects and differentiated according to the given animal's ability for conditioning and perceptual learning. Simplest of all is a direct conditioned-emotional-reaction, as when a punished dog pulls back, trembling and whining, at first sight of a whip; this is a literal transfer of the emotional response to particular objects and situations. It is characteristic of the lower mammals and the very young human child alike that dealing with objects tends to be dominated by such emotional reactions; that the perception of the given object can not be divorced from its emotional elements. Such impulsive emotion-determined reactions to phases of the outer world may be considered the antecedent basis of adult human experience.

In man rather fully and in the chimpanzee to a far lesser extent, the process of socialization and special training leads to a greater freedom from direct impulsive emotional reactions. Through general and special training, mimetic and symbolic, man becomes able to inhibit or reduce his emotional excitement, delaying or redirecting it in appropriate socialized ways. Thus an outstanding difference from lower animals is that man's emotional life is coloured by a highly specialized training in the faking, manipulation or suppression of the outward signs of emotional excitement. Specialized gestures and facial expressions appropriate to countless situations, as well as verbal patterns of diverse forms (*e.g.*, "these flowers convey to you my deep sympathy") express the complex modification through experience of originally direct impulsive reactions. Socialized perceptual training generally dominates in the trained adult, reinforced when necessary by reasoning, with the exception of occasional new situations of startling nature, or situations of unusual tension and provocation. The capacity for impulsive emotionalized behaviour is not lost by any means in adult life. Experiments involving problem-tensions of different degrees suggest that each individual has his limit of socialized resourcefulness, beyond which added strain may subordinate the resources of intelligence and training to emotional outbursts of a more or less impulsive, "primitive" sort.

Thus man differs from lower animals in the extent to which he can subordinate impulsive emotional reactions to the perceptual, meaningful nature of a situation. That this control depends upon the cerebral cortex dominating lower centres, as suggested by Hughlings Jackson, is shown by the relative loss of ordinary emotional restraints under the influence of cortex-inhibiting intoxicants like alcohol, or more permanently when brain tumours or injuries reduce cortical function in man. And in lower mammals such as the cat, after an operation disconnecting the cerebral cortex from the brain stem (presumably releasing lower centres from ordinary cortical restraints), there appear activities normally associated with emotional excitement such as snarling, biting, rapid panting and signs of marked visceral disturbance. It seems that the superior cortical equipment of man accounts for his superiority in acquiring highly specialized emotional controls much as it is responsible for his striking ascendancy in intelligent behaviour.

Capacity for Aesthetic Perceiving.—For the lower mammal, through learning, objects or situations may acquire direct emotional effects such as immediate soothing or immediate distress upon sight, as the perception of a dog disturbs a cat. The capacity appears first in a recognizable but clear form in the mammals. To be sure, in many lower vertebrates, even including some invertebrates, a bright and varying body coloration or interesting patterns of sound serve to attract individuals of the opposite sex. However, the appearance of such colours and sounds is due to physiological changes and not psychological factors concerning an attempt to influence others, and responses to them are unlearned and simple in nature. Neither the simple learned nor the unlearned cases may be considered truly aesthetic, in that the appearance of given attractive features or sounds, or responses to them, hinges upon the production of given emotional gratifications.

The properties of simple aesthetic perceiving may be recognized in the lower primates. Köhler reported that at times chimpanzees would hang material such as bits of plants or fruit skins about their necks or shoulders, to be worn until forgotten, apply materials such as clay to their own bodies or the surroundings and on numerous occasions engage in activities of a crude dancelike nature. Simple motion patterns were observed, such as the movement of a group in single file in a circular path. Or, one of a pair of chimpanzees would stand in place, stamping first with one foot and then the other, while its companion rotated with outstretched arms. Köhler considered these activities related to dancing in a rudimentary way, as the simple daubing and the use of objects on their bodies might be regarded as primitively related to human art. Chimpanzees thus appear to have the rudiments of aesthetic perceiving, since they evidently indulge in such activities because a crude emotional satisfaction is derived from them, and also because of their effect upon other individuals.

Although lower primates seem to possess a rudimentary capacity for art and aesthetic relations with the surrounding world, only man clearly exhibits the ability to create in a systematic manner visual patterns such as paintings, objects of adornment or sound patterns such as musical compositions, in the anticipation of producing emotional experiences on further occasions when these stimulus patterns are presented to their creators and others. Whatever capacity the chimpanzee may possess for personal adornment, dances and other aesthetic activities, it is on a low level of development. The chimpanzee revels in emotional experience in an immediate and present sense; however, the instances are relatively isolated and disconnected, because he is not capable of the highly organized abstract thinking which would unite emotional experiences of a given class into patterns used creatively for a greater future enjoyment. For this it is necessary to have some understanding of one's own personal relation to the situation, and a capacity for preparing to encounter the given class of situation in the future. Because only man possesses this capacity in a well-developed form, he is the one animal clearly capable of systematically comparing classes of objects in terms of their emotion-arousing effects, the only one fully capable of treasuring and resynthesizing emotion-provoking patterns. His superiority in bringing remote intervals of time together through foresight, in mastering and organizing meanings and symbols in reasoning, permits him to control very skilfully the nature of his environment in order to produce given emotional effects in himself and others.

Individual Differences and Abnormal Behaviour.—Normal behaviour may be defined as the pattern most characteristic of a given animal group. The major animal forms have been compared in terms of what capacities are normal or typical of them. Although in general this is a sound practice, it should be recognized that in each animal group from Protozoa to man, there are secondary variations in the species population away from the typical condition in every respect from degree of sensitivity to capacity for modifying behaviour. Generally these are predictable, in the sense that fewer and fewer individuals are found diverging more radically from the

general condition; yet the existence of individual differences within a group in all psychological as well as physiological and anatomical respects is a fundamental and important fact about animal nature. Whether the behaviour pattern is chiefly organized on an unlearned basis as in the insects, or a learned basis as in primates, individuals differ relatively from one another. Some bees are superior and others inferior to most bees in way-finding and food-gathering; not all chimpanzees can stack boxes or solve stick problems; and so on for every class of activity in every animal species.

The above types of individual differences are the regular and expected ones. Truly abnormal psychological deviations sharply divergent from the typical species pattern appear to be uncommon in the lower animals. To be sure there are numerous exceptional kinds of behaviour disorders attributable to pathological or disease conditions. Veterinary science is familiar with a large number of diseases, many of them affecting the nervous system, which distort behaviour in special ways. Thus the signs of rabies or "hydrophobia" in dogs are extreme emotional irritability with a tendency to wild running and indiscriminate biting; the presence of brain tumours may lead to exceptional sleepiness, reduced sensitivity, irritability or depression, or other extraordinary signs. In these diseases, however, whatever psychological difficulties appear are not the true causes of the disorder. Man appears to be the one animal given to incurring in his *regular* existence true mental disorders fundamentally psychological in nature.

It is true that under the stress of extraordinary emotional experiences, lower mammals may exhibit emotional disorders resembling in limited ways the human pattern known as neurosis. An example is the gun-shy dog, which has become extremely fearful in given situations, and perhaps in all unfamiliar situations as well, as a consequence of emotional shock. Disturbances resembling neurotic outbursts have been produced in certain mammals and even in birds and other lower vertebrates, by a modification of the Pavlov conditioned-response technique. A dog, for example, is trained to salivate when a circle is presented, but is shocked when an ellipse appears, then after training is presented with an ambiguous figure resembling both circle and ellipse. The figure tends to call out both learned responses; however, the animal can not make the response and inhibit it at the same time. A marked conflict condition results, with evident signs of great tension, trembling, excited and even violent movements, and typically a more or less complete inability to show any definite signs of his past training. In the face of marked difficulties and frustration in problem situations, where hunger is strong and no response adequate to get food, chimpanzees and other mammals are likely to show violent emotional outbursts and special difficulties such as negativism, inability to respond at all, or a tendency to respond irrelevantly or to leave the situation altogether. If such experiences are frequent, lower primates and human children alike develop responses such as temper tantrums and chronic sulkiness, and may acquire a regular habit of avoiding the issue in each difficult new problem by turning to evasive behaviour or excessive dependence upon others instead of attempting to solve the problem by learning or reasoning. It is quite possible that the frequent experiencing of strain-provoking problem difficulties and tension-arousing frustrations of normal motives (*e.g.*, food, sex) may set up in lower primates the type of personality disorder termed neurosis in man. Perhaps if systematic attempts were made to frustrate the motives of chimpanzees from an early age, as many human parents frustrate their children, chimpanzee personalities with the unenviable distinction of mimicking human "insanity" might well appear.

We may recognize some reasons why personality disorganizations such as neurosis frequently encountered in man are not common among his close animal relatives. One reason is that lower primates are deficient in redirected reasoning, hence are relatively free from the cumulative morbid burden of a pronounced "inferiority complex," for example. Deficient in foresight, they are largely if not entirely freed from the fearful anticipative types of thinking known as "worry" in man. When a chimpanzee is away from a frustrating problem situation, his shortcomings in symbolism prevent it from arising vividly to plague him in other situations. The absent situation virtually ceases to exist for him, and he is free to recuperate; whereas a human is far better able to recreate the situation with its strain, and even enlarge upon it in its absence. Moreover, the lower animal is protected from mental illness in other ways, also based upon his intellectual inferiority to man. If physical escape is possible he leaves the frustrating situation outright, without being held as fixedly by attitudes of personal prestige as man; or he hits upon and adopts as routine some irrelevant response. For instance, after a caged tiger has lost his first frantic responses to confinement, tension arising because of the clash between tendency-to-leave and necessity-of-remaining is reduced through activity such as the incessant circling of his cage in an identical path. The stereotyped behaviour is satisfying in that it displaces emotional tension and thus acts as a safety valve for the animal. This type of *fixation* is irrelevant in that it does not solve the problem of escaping, or getting food or whatever the real difficulty may be; however, it is a successful adaptation in the sense that it permits the animal to survive repeated frustration without becoming wrecked through emotional disturbances. Similarly, fixations such as characteristic delusions often appear in man, and may save the individual from the extreme types of personality disorganization popularly termed "insanity." PSYCHOLOGY, HISTORY OF. The history of psychology is the history of thought about human consciousness and conduct; that is to say, about reason, perception and memory, and also about action, motives and the other determinants of action. On the one hand, the history of psychology merges with the history of philosophy whenever psychology is regarded as dealing primarily with reasoning, thinking, feeling and perceiving; on the other, it merges with the history of physiology when psychology is considered to be the science of that behaviour which is regarded as a function of the action of the nervous system.

GREEK PSYCHOLOGY

Early Theories.—In the 6th century B.C. the development of medical thought had led to recognition of the importance of the brain and the sense organs in reasoning and in perception, two functions which were distinguished from each other. There also appeared quite early the doctrine of the four basic temperaments, dependent on the admixture of the four bodily humours—the blood, the phlegm, the black bile and the yellow bile. Centuries later the temperaments corresponding to these humours were named, respectively, sanguine, phlegmatic, melancholic and choleric. In early Greek thought there was no recognition of a soul which is an agent in the activities of reasoning or perceiving.

The idea of a soul as something resident in the body but capable of existence apart from it came in with the Pythagoreans about the end of the 5th century B.C. Plato developed this conception, distinguishing between the nutritive, sensitive and rational functions of the soul, and assigning them, respectively, to plants, animals and men. He held that these functions represent a developmental hierarchy, each higher level including the lower, and that the development of reason in man may introduce conflict between reason, which is possessed only by man, and desire, which exists also at the animal level. Thus we find in Plato the conception of the soul's activity as constitutive of its basic functions, and the notion that simpler activities develop into more complex, sometimes giving rise to conflict. Such conceptions reappear from time to time in the history of psychology, notably in the psychology of G. W. Leibnitz (1704), J. F. Herbart (1825) and Sigmund Freud (1900), the line of development that led eventually to what is called dynamic psychology.

The Greeks also introduced the doctrine of empiricism into psychology, the doctrine that all the contents of the mind are derived through the senses. Heraclitus (5th century B.C.) held that all knowledge comes to man "through the door of the senses," and Protagoras (*c.* 484–411 B.C.) that the entire psychic life is made up only of sensations. The Stoics used the figure of the *tabula rasa*, the blank wax tablet of the mind upon which experience writes. This is the doctrine that was taken up later in the British school of empiricism.

The Greeks had also a theory of perception. Empedocles (*c.* 490–435 B.C.) supposed that objects give off from their surfaces or pores effluvia, which act upon the senses to furnish knowledge of the external world. Democritus (*c.* 460–370 B.C.) and Epicurus (*c.* 341–270 B.C.) described these projections as faint images, simulacra or eidola of the objects which, being conducted to the mind, give it acquaintance with the objects which they represent. This naive view that perception represents an object by being similar to it is so simple and attractive that it continued to persist, in spite of opposition, having been contradicted by Johannes Müller

(1801–58) and by various critics in the 20th century.

Aristotle.—Aristotle (384–322 B.C.) has been said to be the greatest mind in the history of thought. Certainly his recorded wisdom influenced the scholarly thought of Europe more completely and for a longer time than have the writings of any other one man. He was both philosopher and scientist, theorizer and empiricist, and the psychology found in his *De Anima* and other writings determined accepted psychological doctrine down to the end of the 18th century.

In Aristotelian doctrine the body has a *pneuma,* which is connate with it and pervades it. This pneuma (animus, spirit) effects the integration of the organism by its appropriate movement within the body. Aristotle seems to have believed that the pneuma moved within the blood vessels, for he knew nothing about the nerves. Later psychologists substituted "animal spirits" for the pneuma and assumed that the nerves were their conductors, but the basic idea of integration by an internal pervasive agent was Aristotle's. The soul, according to Aristotle, is the *entelechy* of the body; that is to say, it is the perfection of unity toward which the functions of the body are directed. This stress upon the unity of the soul and the importance of considering the total organism in the understanding of perception and action persisted through the ages into modern psychology and is the chief means of distinguishing psychology, which deals with total action, from physiology, which deals with the functions of parts.

Aristotle localized the psychic functions in the heart. That was an error. Plato and Pythagoras had been correct in placing them in the brain. Much later, Galen (*c.* A.D. 130–*c.* 200), one of the greatest physicians of antiquity, synthesized the two views by arguing that the animal spirits are stored in the ventricles of the brain, flow thence to the ventricles of the heart, whence they are distributed to the body by the arteries.

The specification of five separate senses is due to Aristotle. External forces, he held, act upon the body and their effects are transmitted by the pneuma to the sensorium, where the unity of the senses is preserved, as can be seen in such perceptions as those of shape and size, which are common to both sight and touch.

Aristotle distinguished clearly between the cognitive and conative aspects of the soul. On the one hand, he noted a cognitive series of functions from sensation to reason; on the other, a conative series from simple desire through wish to will. The basic conative drive Aristotle called *orexis.* In terms of it he derived a dynamic psychology, which for him included ethics.

Hellenistic Period.—After Aristotle there ensued the Hellenistic period, which was distinguished, among other things, by the brilliance of Alexandrian science in the 3rd century B.C. Herophilos (4th century B.C.) and Erasistratos (*c.* 304–258 B.C.) discovered the nervous system, the nerves leading to the brain and spinal cord. They even distinguished between motor and sensory nerves, a distinction that was not validated until 2,000 years later. In general, however, Alexandrian science did not promote psychology, for the mind was not then supposed to be understood in terms of natural law, and psychology and physiology became during the course of many centuries more and more widely separated.

The Stoics (*c.* 300 B.C.) contributed both the notion of instinct and of conscience, the latter signifying an inner sense of conformity with innate reason. In general, the Christian schools took over the pagan philosophy and with it Aristotle's psychology. By the 3rd century A.D. Plotinus (*c.* A.D. 203–270), promoting a return to Platonism, established psychology as a pure science of experience based upon introspection described without regard to underlying physiological processes. Augustine (A.D. 354–430) continued this tradition, establishing what came presently to be the accepted psychology of the Christian Church. Thereafter, through the middle ages, psychology consisted largely of a repetition and elaboration of the dicta of Aristotle and Augustine.

EARLY MODERN PSYCHOLOGY

All through the history of psychology we find a dichotomy in respect of which the various views and theories about mind and the definitions of psychology can be organized. In the absence of accepted terms, we may call the one the phenomenological approach and the other the mechanistic approach. The phenomenological approach to the problems of mind includes the description of immediate experience, directly as it comes to the observing person. It tends to regard mind as separate from the body and to get along with only minor reference to physiology. It is often an unexperimental psychology, being available to philosophers by their own introspection. The modern representatives of the phenomenological approach are Franz Brentano's intentionalism, Wilhelm Wundt's introspectionism, and Gestalt psychology. The mechanistic approach, on the other hand, deals more with causal relations than description. It is thus forced to look to bodily functions and physiological processes in order that it may subsume psychological events under natural law. Its modern representatives are U.S. functionalism, behaviourism and operationism. In general, up to the year 1910 and even later, the British and German traditions were phenomenological, the French and U.S. mechanistic.

Seventeenth-Century Psychology.—Plotinus and Augustine had left psychology phenomenological and descriptive. In the 16th century, with the tendency to recognize that causal principles determine behaviour, occurred the beginnings of a dynamic psychology. Niccolo Machiavelli (1469–1527) had effectively expounded the thesis that men are controlled more by their passions than by reason, and various other less well-known writers had developed that theme. Still later we find Francis Bacon (1561–1626) promoting a naturalistic view of man's conduct.

Thomas Hobbes (1588–1679), who published his *Leviathan* in 1651, was essentially a mechanist, a dynamic psychologist. He was primarily concerned with the conduct of man, especially his social conduct. Hobbes distinguished between innate motives and those that are acquired in experience. He observed how pleasure and pain, pride and fear, determine human action. He is perhaps, before John Locke, the originator of British empiricism, because of his stress upon the role of experience in establishing the nature of man; but mostly he was a social dynamic psychologist.

The great founder of the mechanistic tradition in psychology was René Descartes (1596–1650), a philosopher who also performed anatomical dissections and physiological experiments. He established in the common sense of the next three centuries the dualistic notion that mind and body are separate, that mind is unextended substance and body extended substance, the mind occupying the body and interacting with it at a determinate point in the brain. Thus, body affects mind, and mind body. Animals, who have, Descartes thought, no rational souls, are automata, machines which behave in accordance with their properties and the forces which act upon them. Thus, the history of reflex action, as basic to the mechanistic conception of mind, must be dated from Descartes. He called the total motion of the animal spirits along the nerves through the valves of the brain and out again along other nerves to the muscles *undulatio reflexa,* since the nervous system, in redirecting the course of the animal spirits to produce movement, may be regarded as "reflecting" them.

The mechanistic tradition was continued in France during the 17th century by the contributions of Nicolas de Malebranche (1638–1715).

Scientific cognizance was also being given at that time to some of the problems of visual perception. Leonardo da Vinci (1452–1519) had already discussed some of these problems—colour contrast, the relation of light and shade and of aerial perspective to the perception of the third dimension, the problem of the transparency of near objects in binocular vision (caused, of course, by the different angles at which the two eyes view the scene) and the similarity of the eye to a camera. In 1604 the astronomer Johann Kepler (1571–1630) noted that the crystalline object in the eye must be a lens and not the percipient organ, and that it must throw an inverted image on the retina. He, therefore, decided that the retina must be the percipient organ. Kepler then raised the question as to why we see right side up when the retinal image is upside down, falling into the common error of thinking that external objects must be represented by similar patterns in the brain. Later Descartes demonstrated, using the excised eye of a bull, that

the inverted image is actually formed by the lens at the back of the eye.

The century saw two other important discoveries in the field of sense perception. In 1638 Galileo (1564–1642) showed that the pitch of tones depends on the frequency of vibration of the air, that the ratio is two to one for the octave and three to two for the fifth. In 1672 Isaac Newton (1642–1727) presented to the Royal society his first paper on colour theory, in which he showed by experiments with a prism that white is a mixture of colours, a discovery that was at first met with incredulity by his scientific colleagues. Newton worked out the laws of colour mixture, and his *Opticks,* after a long delay, was published in 1704.

Eighteenth-Century Psychology.—The French mechanistic tradition was continued by J. O. de Lamettrie (1709–51), who published his *L'homme machine* in 1748; by E. B. de Condillac (1715–80), who is noted for his analogy of the human organism to a statue, which, provided with a single sense, acquires through experience the attributes of a human mind; and by P. J. G. Cabanis (1757–1808), who extended the knowledge of reflex action and argued—he was interested in the reflexes of victims of the guillotine—that consciousness is dependent only on the action of the brain and not of the spinal cord. Contemporaneous with Cabanis was M. F. X. Bichat (1771–1802), who has been called by some the founder of physiological psychology.

The important events of the 18th century occurred, however, on the phenomenological side of psychology, especially in connection with the development of British empiricism and associationism.

In a sense, British empiricism began with Hobbes, but its formal initiation was the publication in 1690 of the *Essay Concerning Human Understanding* by John Locke (1632–1704). Locke's argument was that the mind is constituted of ideas, all of which are gained from experience, most of them by way of the external senses, some of them by reflection, which is the inner sense by which the mind becomes aware of its own operations. Although Locke added a chapter on association of ideas to a later edition of his *Essay,* the doctrine of association became of importance only with his successors.

Bishop George Berkeley (1685–1753), famous for his subjective idealism, inverted Locke's proposition. The problem, he thought, is not how the ideas get into the mind from outside by way of the senses, but rather, since the mind knows nothing other than the ideas of which it is constituted, how we ever obtain a belief in the existence of the external world. Berkeley undertook to answer this question and many other related ones by an appeal to experience and a principle which is essentially that of the association of ideas. He also wrote a *New Theory of Vision* (1709), which contributed both to the systematic theory of empiricism and to the psychology of visual perception.

David Hume (1711–76) comes next in this line of descent. He differentiated impressions, which depend upon a present stimulation, from ideas, which are "faint copies" of the impressions. This is the distinction between sensation and image in later terminology. Hume also undertook to explain the concept of causation as resulting from the habitual sequence of the impressions of two events, thus reducing causation to association. Because Hume lent his great influence to the conception of ideas as mental elements whose compounding explains all of the more involved mental phenomena, he is often regarded as the chief enemy of holism, as it is found in the modern school of Gestalt psychology.

David Hartley (1705–57), while less important than his predecessors in this school, stands out because of the clear, simple and emphatic associationism which his *Observations on Man* of 1749 presents. Taking association from Locke and the notion of transmitted vibratory motion from Newton, he built up a system in which the laws of association of ideas were paralleled by laws of association of vibrations (correlated with sensations) and diminutive vibrations (correlated with ideas, images) in the nervous system. This sharp and uncompromising presentation of the associationistic principles, combined with a simple psychophysical parellelism of mind and nervous action, served to make the nature and implications of associationism clearer than could the more subtle exposition of an abler mind, like Hume's.

The French tended to take over associationism and combine it with their mechanistic psychology. Condillac's statue (*see* above) was supposed to build up its sensations in experience by means of associative principles.

Meanwhile in Germany there was G. W. Leibnitz (1646–1716), Locke's contemporary. Leibnitz's chief contribution to psychology was his insistence on the active nature of the mental units, his "monads," which are forever striving for development according to their pre-established nature. The association of ideas in the British school tended to create the picture of fixed mosaics of mental elements which make up the complexes of the mind. Leibnitz, on the other hand, remained on the side of a dynamic psychology, which insists that activity and purpose are basic in mental life. He believed that his monads develop independently, and that the results of their interrelations are simply coincidences resulting from a harmony pre-established among them and not from causal interaction. The conception of psychophysical parallelism between mind and body grew out of this Leibnitzian notion. Leibnitz also contributed to psychology the concept of apperception, which he held to be the consequence of the summation of many little perceptions. His notion that the apperception of the roar of the sea is the sum of the "petites perceptions" of the noise of every falling drop of water is well known. It gave rise to the concept of the threshold of consciousness as it is found in the writings of Herbart, in G. T. Fechner and psychophysics, in Freud and psychoanalysis.

After Leibnitz the development of German psychology passed into the hands of a number of less well-known men in the Berlin academy, of whom J. N. Tetens (1736–1807) is perhaps the best known. The chief contribution of these philosopher-psychologists was to stress the importance of feeling as a third primary category of psychology. Heretofore cognition and volition, knowing and acting, had constituted chief subdivisions in systematic psychology. Now the affective life was added as a third, and this threefold division of the subject matter of psychology—thinking, feeling and doing—continued as the standard classification all through the 19th century and well into the 20th.

PSYCHOLOGY IN THE 19TH CENTURY

The history of psychology in the 19th century can be viewed as a history of schools of systematic thought about the mind (associationism, introspectionism, intentionalism, evolutionism, functionalism) and of fields of experimentation and research (physiological psychology, experimental psychology proper, phenomenological observation, abnormal psychology and the mental tests in conjunction with the functional psychology of individual differences).

Associationism.—While the Scottish philosophers—Thomas Reid (1710–96), Dugald Stewart (1753–1828) and Thomas Brown (1778–1820)—are not properly classified as associationists, the theory of perception that developed under their thought contributed to the importance of associationism. Brown's theory is the culmination of the discussion. He distinguished between sensation and perception, holding that perception, unlike pure sensation, refers to or intends an external object. In perception the sensations that first arise suggest—by association, but Brown preferred the word "suggestion" to "association"—other sensations which specify the object which is intended. For example, the smell of a rose suggests the sight of a rose, which is enough to identify the object as a rose. In other words, meaning arises in perception by the compounding of two or more sensory elements, and that theory is really the core of associationism: meaning is given in consciousness by the associative compounding of ideas.

It was James Mill (1773–1836) who expressed this view in simplest and clearest terms in his *Analysis of the Human Mind* in 1829. In fact, he reduced the theory to an absurdity by carrying it to its logical conclusion. At the end of his chapter on association of ideas, he noted that the idea of any object is a fusion of the ideas of its components. "Brick is one complex idea, mortar is another complex idea; these ideas, with the ideas of position and quantity, compose my idea of a wall." Finally, he asked: "How

many complex ideas are all united in the idea of furniture? How many more in the idea of merchandise? How many more in the idea called Every Thing?" That was the difficulty: the associationists thought that the idea of everything must be a compound formed by association of every idea of a thing.

John Stuart Mill (1806–73), James Mill's son, made no such error. He avoided the difficulty by noting that a combination of elements often generates something totally new in the compound, so that the parts are lost and the new product gained. This is the theory that Wundt called creative synthesis, that others much later called emergence, that became still later the basis of Gestalt psychology. J. S. Mill also argued that the unrealized potentialities of association play their role in the mental life: an object is, he argued, the "Permanent Possibilities of Sensation"; that is to say, the sensations that it could arouse. As an object, it is believed to be permanent, in spite of the evanescent nature of experience, because these possibilities of sensation are permanent.

Alexander Bain (1818–1903) is the representative of associationism in the latter half of the 19th century. He combined with associationism the growing interest in physiological psychology. Herbert Spencer (1820–1903) represents an influential evolutionary associationism, a doctrine that worked in with the trend of thought in England after Charles Darwin's influence had become dominant. From this point associationism passes over into the introspectionism of Wundt and his followers.

Introspectionism.—Wilhelm Wundt (1832–1920) has been called the founder of the new scientific psychology of the 19th century. Certainly he was its vigorous promoter. He called it physiological psychology and experimental psychology. His *Grundzüge der physiologischen Psychologie* was a systematic text and also a general handbook of the new science, and it ran to six editions from 1874 to 1911. Wundt founded the first formal laboratory of psychology at Leipzig, Ger., in 1879. He started the first journal devoted to experimental psychology in 1881. For 40 years he was the most important and influential figure in German psychology.

As a systematist he was an elementist and an associationist, for he described the sensations and feelings that are the mental elements of psychology, and showed how they are compounded by association into ideas and perceptions (*Vorstellungen*) which are meaningful and refer to objects. The turn of events, however, put more emphasis upon Wundt's insistence that introspection—the verbal description of the immediate data of experience—is the chief method of psychology. Although Wundt called the new science physiological psychology, he was insistent that physiological processes parallel and do not constitute the psychic processes. The phenomena of consciousness, he held, are observable without reference to the body to which they belong.

Wundt's position was continued by Oswald Külpe (1862–1915) and E. B. Titchener (1867–1927). They were both his students. Külpe is best known for his attempt to apply the introspective method to the study of thought in the researches of his Würzburg school (1901–09), which showed—this appears to be the verdict of time—that introspection is inadequate to the observation of the unconscious directive tendencies which preserve the purposive nature of thought. Titchener went to the United States in 1892 and there upheld the Wundtian position for 35 years. There can be no doubt that U.S. functionalism was more clearly understood because it contrasted so strongly with Titchener's unyielding introspectionism. Titchener hoped that psychology could eventually get along without any relation to physiology.

J. F. Herbart.—The influence of Herbart (1776–1841) was so great during the first half of the 19th century that separate mention must be made of him. He defended a psychology founded upon experience, metaphysics and mathematics, and denied the possibility of experimenting upon mind. He conceived of ideas as active and struggling, one with another, for a place in consciousness. Thus, as we have already noted, he provided, in following Leibnitz, both psychophysics and psychoanalysis with the concept of the threshold of consciousness and also with the notion of unconsciousness that lies below the threshold. Much of Wundt's work was clarified by his opposition to Herbartian ideas.

Intentionalism.—The traditional psychology that had come down from Aristotle and Augustine was reformulated by Franz Brentano (1838–1917), a Roman Catholic priest and a psychologist of wide influence, as what is called act psychology or intentionalism. The contrast between Brentano's and Wundt's psychologies was heightened by the fact that both men published their crucial systematic texts in 1874. Brentano contended that the conscious mind is constituted of acts—ideating, judging, feeling ("loving-hating"). Wundt had divided mind into more static elements—sensations and the feelings. The acts, Brentano held, have objects which they "intend" or are directed upon, and these objects "inexist" within the act. If I see a green, then the act of *seeing* is the mental datum and the *green,* the object of the act, exists intentionally within the act, thus in part determining its nature.

Brentano's psychology claimed many followers in the late 19th and early 20th centuries, especially in Austria. Külpe's later systematic views were affected by Brentano's thinking, as was also the system of Carl Stumpf (1848–1936), who, holding the chair at Berlin, found himself in opposition to Wundt on many occasions.

In England, James Ward (1843–1925) was markedly influenced by Brentano. Ward distinguished between cognition, feeling and conation, finding all three present in the representative psychological act. G. F. Stout (1860–1944) followed the tradition of Ward, and William McDougall (1871–1938), who in 1919 transferred from England to the United States, upheld a purposive psychology that showed this same influence.

Evolutionism.—One effect of Charles Darwin's theory of evolution was to interest psychologists in mental inheritance and in the phylogenetic development of mind. In 1869 Francis Galton (1822–1911) published *Hereditary Genius,* a study which showed that men of eminence in England tend to be related. In those days the data were taken as demonstrating the biological inheritance of mental ability, although later it became evident that these great men owed their eminence at least in part to their education and their socioeconomic status. Darwin himself argued for the phylogenetic development of mind in his *Expression of Emotion in Man and Animals* (1872). Thereafter the versatile Galton conducted other studies on mental inheritance among persons of ability and on the resemblances of twins. He advocated the inventorying of the abilities of the British nation, inventing some simple tests whereby such an inventory could be made (or so he thought). He coined the word "eugenics," meaning by it the improvement of the race by selective parenthood.

G. J. Romanes (1848–94) carried on this interest in England by his studies of animal intelligence and his books on mental evolution in both animals and man. He coined the term "comparative psychology" for the study of the relationships between the minds of different animal species. C. Lloyd Morgan (1852–1936) carried comparative psychology further, and this field of endeavour was then taken up in the United States (*see* PSYCHOLOGY, COMPARATIVE).

British evolutionism also found support in the United States. J. M. Baldwin (1861–1934) was the Romanes of the U.S., with two important books on mental evolution. G. Stanley Hall (1844–1924) admitted that his many interests in the different phases of human capacity were held together by his abounding faith in the importance of evolution. James McK. Cattell (1860–1944), directly influenced by Galton, coined the term "mental test" in 1888 and lent his support to the development of the psychology of individual differences. In the United States evolutionism formed the background of functionalism.

Functionalism.—In the 1880s and 1890s the United States had the temper of a young nation, a nation still imbued with the practical spirit of conquering a continent. It sent its psychologists to Wundt at Leipzig that they might learn the best of what was new in psychology, but U.S. psychology never accepted the pedantry of the German approach to the subject. The Americans were bound to be practical and functional, to see mind in terms of its use for the survival of the organism in the struggle of the race for existence and in the social competition of the individual

for success. Hence, the United States accepted evolutionism enthusiastically and created its own psychology, which was functional.

William James (1842–1910), pioneer of psychology in the United States, introduced the functional approach to the problems of the mind in his *Principles of Psychology* of 1890. Cattell, as has just been noted, supported a functional psychology in his advocacy of the use of mental tests in the 1890s and later. The formal school of functionalism was, however, founded by John Dewey (1859–1952) about 1896 and was continued at The University of Chicago by James R. Angell (1869–1949) and his associates.

Functional psychology admits the data of both consciousness and behaviour to its domain, for it is primarily concerned with what enables the organism to adapt to the varying conditions of its environment. Functional psychology is the psychology of the "Is-for," as Titchener remarked, the psychology of how to be successful, and thus it is appropriately American. The school disappeared after Dewey and Angell left Chicago, and behaviourism was ready to replace it (*c.* 1916). Nevertheless, the spirit of functionalism, since functional psychology is a natural medium for physiological psychology, animal psychology, differential psychology, normal psychology and applied psychology, came to stay and has characterized most of the psychology of the United States from the beginning. (*See* section on *Functional Psychology* below.)

Physiological Psychology.—The century saw great progress in nerve physiology. In 1811 Charles Bell (1774–1842) distinguished between sensory and motor nerves, showing that the two kinds of nerves have separate roots at the spinal cord. François Magendie (1783–1855), the French physiologist, discovered independently in 1821 this same fact, which is called the Bell-Magendie law. As electrical currents and galvanometers became available in the 1840s, the electrical properties of nervous conduction came to be investigated, and the mysteries of the animal spirits were dissipated by the accumulation of observed facts. In 1850 H. L. F. von Helmholtz actually measured the velocity of the nervous impulse along a nerve, a discovery which met at first with as much incredulity as Newton's report in 1672 that white is a mixture of colours.

There was also a great deal of work on the localization of functions in the brain. F. J. Gall (1758–1828), a brain anatomist of considerable ability, formulated the theory of phrenology about 1800, the theory that temperament can be assessed from a study of the conformation of the skull, since the development of crucial areas in the brain would be reflected in the shape of the skull. The popularity of this view was not readily destroyed by the scientific opposition which it received. Pierre Flourens (1794–1867) undertook experiments upon animals to determine more exactly the functions of the various parts of the brain, discovering about 1825 that certain gross areas are essential to certain functions but that fine localization is often (perhaps always) missing. In 1861 Paul Broca (1824–80) discovered the speech centre in the left cerebral hemisphere, and then in 1870 G. Fritsch and E. Hitzig localized motor centres precisely by electrical stimulation of the brain. The last quarter of the century saw the growth of a firm belief in exact cerebral localization, a belief somewhat weakened by the discoveries of the 20th century.

Johannes Müller (1801–58), sometimes known as the father of experimental physiology, affected psychology by his doctrine of specific nerve energies, which he first published in 1826. The doctrine was really a theory of sensory quality, for Müller sought to demonstrate that the sensory quality aroused by stimulation depends on the particular nerve excited and not directly on the nature of the stimulus. Pressure on the eyeball produces a sight, light on the skin elicits warmth and electricity on any nerve arouses the peculiar quality ("energy") that belongs to the nerve. Later Helmholtz extended this doctrine to differences of quality within a given sense, even seeking in the inner ear a means whereby each one of several thousand distinguishable pitches could be put onto a corresponding nerve fibre. Later research indicated that the specificity of different nerves and fibres lies not in a peculiar nervous energy but in the points in the brain to which the fibres lead. (*See* also PSYCHOLOGY: *Physiological Psychology.*)

Experimental Psychology.—Experimental psychology (*q.v.*) proper began with sense physiology, the study of how sensory experience is dependent on stimulation of the sense organs, which is what Fechner later called psychophysics (*q.v.*). Newton's discovery of the laws of colour mixture and Galileo's finding about the dependence of tonal pitch on stimulus frequency were psychophysics. In the 19th century the increased interest in sensory physiology advanced psychophysical investigation greatly.

Research on vision predominated. Thomas Young (1773–1829) published his theory of colour vision in 1801, the theory that Helmholtz later established. The poet, J. W. Goethe, in 1810 published his *Zur Farbenlehre,* an elaborate, dictatorial phenomenology of colour; its immediate influence was great because of the enormous prestige of its author. J. E. Purkinje (1787–1869) also wrote a phenomenology of vision (1819, 1825) which contains the first accounts of several important phenomena; for example, the "Purkinje phenomenon" of the changes of hues as illumination shifts from daylight to night vision. Johannes Müller's first important book (1826) was on visual physiology.

In 1834 E. H. Weber (1795–1878) published his experiments on tactual sensibility, experiments which included his finding that magnitudes of stimuli that are just noticeably different in perceived intensity bear a constant ratio to each other. G. T. Fechner later named this principle Weber's law (*q.v.*). It is only approximately true.

The century's two most important experimental psychologists were Fechner and Helmholtz. Fechner (1801–87) was, by way of his *Elemente der Psychophysik* of 1860, the founder and promoter of psychophysics, and some say of experimental psychology, although that distinction is generally reserved for Wundt. Fechner was obsessed by his realization that it is possible to measure sensation as well as the sensory stimulus, and to state in an equation the relationship between the two measures. He described, developed and formalized the three fundamental psychophysical methods of sensory measurement. He named Weber's law and worked out the quantitative relationships which it implies. He established the concepts of the absolute limen (just noticeable sensation) and the differential limen (just noticeable difference between sensations), and the methods of measuring them. In short he put sensory psychology on a quantitative basis.

H. L. F. von Helmholtz (1821–94) made the greatest factual contribution of any one man to experimental psychology. The results of his observations and thought appear in the three volumes of his *Handbuch der physiologischen Optik* (1856–67) and the one volume of his *Lehre von den Tonempfindungen* (1863), which for more than half a century remained respectively the standard reference works on visual and auditory psychophysics.

Fechner's methods and Helmholtz's facts helped Wundt in the founding of experimental psychology. The last quarter of the 19th century saw the founding of many psychological laboratories, first in Germany and then in the United States. Wundt's demonstrational laboratory in 1875 was the first to be created, and his institute at Leipzig in 1879 was the first formal laboratory; William James also had an informal laboratory at Harvard college as early as 1875. Research followed the founding of the laboratories—first on sensation and perception, then on action, then on memory and learning, with the bare beginnings of an experimental psychology of thought and attitude showing before 1900.

Abnormal Psychology.—The more important part of the history of abnormal psychology (*q.v.*) would consist of a history of witchcraft, animal magnetism, hypnotism, hysteria, psychoanalysis and neurosis. Many of the neurotics of the 17th century were considered to be sorcerers or witches. Late in the 18th century F. A. Mesmer (1754–1815) discovered that he could exercise over other persons a peculiar power which he called animal magnetism and which others came later to call mesmerism. Toward the middle of the 19th century James Braid identified this state with some of its scientific conditions, calling it neurypnology which later became hypnotism (*q.v.*). In the last quarter of this century

J. M. Charcot (1825–93) at the school of the Salpêtrière near Paris undertook the study of hysteria, a neurotic state in which the extreme symptoms resemble the symptoms of hypnosis. Charcot thought that only hysterical persons could be hypnotized, but in that belief he was wrong. Charcot's place as the foremost psychopathologist of France was taken by Pierre Janet (1859–1947), who published the classical text on hysteria in 1892.

Sigmund Freud (1856–1939) was also for a brief time a student of Charcot, but Freud's development of the method and concepts of psychoanalysis were his independent doing.

Psychoanalysis (*q.v.*) may be said to have got under way with Freud's publication of his book on the interpretation of dreams in 1900. Its further development and the emergence and establishment of the dynamic psychology of neurosis, which made use of many psychoanalytic terms and concepts, are largely a history of events in the 20th century.

The history of abnormal psychology is, of course, related to the history of psychiatry (*q.v.*). In Germany Emil Kraepelin (1862–1915), one of Wundt's pupils, contributed notably to psychiatry and to the classification of the abnormal states with which psychiatry deals.

Differential Psychology.—We have seen how Galton became interested in individual differences in mental capacities and formed a scheme of inventorying the British nation in order to assess its psychological resources. He invented a number of simple mental tests and Cattell, in the United States, made up some more and promoted their use. Galton's and Cattell's tests were for the most part simple tests of sensory and motor capacity and did not adequately measure intellectual and scholastic abilities. In France Alfred Binet (1857–1911), assisted by Victor Henri, was developing certain concepts of personality and tests of intelligence for children. Out of that work there emerged in 1903 Binet's intelligence tests, which, because they measured more important intellectual capacities, were accepted in preference to the sensory and motor tests. The history of intelligence testing, and later of testing for special abilities and aptitudes, belongs, however, to the 20th century.

PSYCHOLOGY IN THE 20TH CENTURY

For the most part the history of the psychology of the first half of the 20th century is given in the special articles on psychology.

(*See* PSYCHOLOGY and cross references there cited.) The following paragraphs give the general perspective.

Schools.—The century began with introspectionism and functionalism well established in the United States, introspectionism and intentionalism dominating the psychology of Germany, abnormal psychology important in France and evolutionism in England. Gestalt psychology began in Germany about 1912 as a reaction against Wundtian introspectionism, and its leaders came to the United States in the 1930s after Adolf Hitler came to power. Behaviourism began in the United States about 1913 as a protest against both introspectionism and functionalism, but actually behaviourism was not inconsistent with functionalism, and presently it took over the practical and mechanistic values that had been the occasion for functionalism. The attack on old-fashioned analytical introspectionism was successful, and in the late 1920s Gestalt psychology and behaviourism found themselves practically in possession of the field. With their missions thus more or less accomplished, both these schools tended to die out or at least to lose their aggressiveness during the 1930s. Psychological operationism came in at this time to supplant behaviourism as a more sophisticated mechanistic view of psychology, and the outstanding systematic issue in the early 1940s seemed to be whether the Gestalt psychologists could save consciousness, as observed in direct experience, for psychology, or whether the operationists would succeed in having it reduced to the behavioural terms which define the manner of its observation. In general, the operationists tended to support physiological psychology, whereas the Gestalt psychologists relied more often on the modern substitute for introspection which they call phenomenology. (*See* BEHAVIOURISM; PSYCHOLOGY; *see* also special sections on *Functional Psychology* and *Gestalt Psychology* below.)

Trends.—The first half of the 20th century was marked by the shift of leadership in psychology from Germany to the United States, by a decrease in the importance of schools and an increase in the importance of scientific research, by the diversification of psychology into many special fields, each possessed of its own techniques and special knowledges, and by the growth of applied psychology in its various professional aspects, in England and Germany as well as in the United States.

Experimental psychology, the general scientific psychology of sensation and perception, feeling and emotion, learning and thought, response and action, remained the expanding core of modern psychology, although it could scarcely be said to dominate a subject which now had so many special fields. *Animal psychology*, which began the century as an independent field of research, became amalgamated with experimental psychology, at first under the influence of behaviourism, and later because most of the experiments in general psychology, especially the experiments in the field of learning, could be conducted more efficiently with animal subjects. I. P. Pavlov's researches on the conditioned reflex re-enforced this association. *Physiological psychology* required operative techniques and was likewise fairly independent of experimental psychology at the beginning of the century, but also became fused with it. By 1940 the distinctions among these three fields had almost disappeared. (*See* ANIMAL PSYCHOLOGY; EXPERIMENTAL PSYCHOLOGY; PSYCHOLOGY: *Physiological Psychology.*)

Differential psychology developed steadily from the beginnings of mental testing with Galton, Binet and Cattell. Up to about 1920 the testing of "intelligence" was the most important activity in this field. About that time psychologists began to realize that social, economic and educational factors can affect ability to do well in an intelligence test, and that biological inheritance is less important than had been supposed. C. E. Spearman in England began in 1904 the development of those statistical correlational methods of the analysis of abilities that later resulted in factor analysis. These improved methods of analysis turned attention away from general intelligence toward the factoring out of the personality those special abilities and aptitudes which function independently in the organism's struggle for success. It is obvious that a great deal of the development of differential psychology has thus been functional and in the interests of applied psychology. (*See* DIFFERENTIAL PSYCHOLOGY; INTELLIGENCE OR UNDERSTANDING.)

Abnormal psychology was quite distinct from general psychology for fully three decades of the century. Since it dealt with the functional disorders and thus with motivation, it got ahead with the problems of personality much faster than did general psychology. *Psychoanalysis* also constituted an attack on the problems of motivation and personality, and its ideology came largely to be accepted by psychiatrists and psychologists, even when they repudiated its techniques and certain of its tenets. It was this development of abnormal psychology throughout the first three decades of the century that gave rise in the 1930s to a vigorous dynamic psychology. (*See* ABNORMAL PSYCHOLOGY; PSYCHOANALYSIS.)

Dynamic psychology arose because of the great interest in human motivation. By 1925 it was beginning to concern psychologists more and more. Dynamic psychology provides a general background for many applied psychologies, like *clinical psychology*, and the techniques of counselling and guidance. *Child psychology*, although it grew out of evolutionism and the interest in genetic psychology in the late 19th century, has been essentially dynamic psychology, and child guidance has become an important branch of applied psychology. (*See* CHILD PSYCHOLOGY; PSYCHOLOGY: *Clinical Psychology.*)

Educational psychology was also principally a growth of the 20th century. It was stimulated by the development of psychological tests and by the general acceptance of the concept of intelligence as the chief intellectual dimension of maturation in childhood and adolescence. Educational psychology has been, of course, closely associated with child psychology and dynamic

psychology. (*See* PSYCHOLOGY: *Educational Psychology.*)

Social psychology has its roots in the *Völkerpsychologie* of the Germans in the 19th century and in the work of certain French writers, especially Gabriel de Tarde and Gustave le Bon. In 1908 William McDougall's *Social Psychology* based social behaviour on the instincts, of which he furnished a classification. After that time social psychology became dependent for its theoretical structure upon those primitive drives or needs which the dynamic psychology of any given period could provide. In the 1930s social psychology was becoming applied, notably through the development of public-opinion polling and the analysis and control of propaganda. In World War II the techniques of the social psychologists were used broadly for the assessment and control of opinion and attitudes and for the gathering of psychological information about large social groups. In such undertakings social psychology was found to be closely related to social anthropology and to certain modern empirical movements in sociology. (*See* section on *Social Psychology* below.)

Applied psychology was the term used for psychotechnical endeavour prior to 1920. Thereafter the special applied psychologies began to make their appearance. We have already noted the modern concern with educational psychology, with clinical psychology, with counselling and guidance of adults and children (as well as the aged) and with applied social techniques. In addition to these there was some development of *legal psychology* and, after 1920, a great deal of interest in *industrial psychology* which, apparent first in England, was promoted subsequently in the United States and greatly furthered by the successful use of psychology in World War II. Industrial psychology is concerned with the selection and training of personnel, and the establishment of the most efficient conditions for work. Efficiency depends upon the proper design of machines, the reduction of fatigue, the promotion of good health and the maintenance of good morale in the relation between worker and employer. Thus, industrial psychology makes use of many of the principles of perception, sensorimotor co-ordination and learning which general psychology develops, and of dynamic psychology, differential psychology and social psychology. (*See*, in addition to the cross references just cited, INDUSTRIAL PSYCHOLOGY; PSYCHOLOGY: *Legal Psychology.*)

FUNCTIONAL PSYCHOLOGY

Functional psychology is that point of view which emphasizes the biological significance of mental activities, holding that conscious processes, like organic activities, appear and function in response to the needs of the total organism in achieving a more adequate adjustment to its environment. The movement which bears the name functionalism had its roots in the Darwinian evolutionary viewpoint, the biologically oriented psychology of William James, the instrumentalism of John Dewey and the interest in animal psychology. Under the leadership of James R. Angell and Dewey, functionalism, from 1894 on, became the dominant viewpoint of the laboratory of experimental psychology at The University of Chicago. Though its leaders had no intention of developing a unique school, their viewpoint became crystallized through the necessity of defending it against attacks. In stressing the role of conscious processes in everyday living, they seemed to their critics to violate the doctrine, then current, of mind-body parallelism. Their assumption that mental functions develop in response to the organism's adjustmental needs was criticized as teleological; yet, biologists had adopted a similar assumption with impunity. Their attempt to deal with mental functions introspectively met criticism on the ground that functions are meanings, not content, and cannot be objects of introspection. Functional psychology, however, never limited itself to the introspective approach; it investigated activities in terms of what they accomplished, the end product, utilizing both introspection and objective observation. The objection that functionalists use the term function ambiguously, at one time meaning the *process,* at another the *end* served by it, was answered by Harvey A. Carr, who followed Angell as director of the Chicago laboratory. He pointed to a common identity of these two usages in the mathematical term "function," which implies a contingent relation, whether of act to structure, or of means to end. Hence, the distinction made by R. S. Woodworth between primary and secondary functionalism was unnecessary. Carr made mental activity the subject matter of psychology, avoiding any dualistic implications of the term by identifying it with that entire group of psychophysical processes involved in adaptive behaviour; *i.e.*, acquiring, retaining, organizing, evaluating, and subsequently utilizing experiences in the guidance of conduct. By opening the way for the study of behaviour as a legitimate part of psychology and by insisting that mental activity be considered in its practical everyday setting, functionalism paved the way both for the behaviouristic movement and for the phenomenal expansion of the applied branches of psychology in the United States.

GESTALT PSYCHOLOGY

Gestalt psychology deals with mental facts which are ignored when merely analytical procedures are used in psychology. That such facts exist was first discovered in perception. For instance, in customary analysis a visual field was regarded as composed of local sensations, each of which corresponded to a local physical stimulus. But in 1890 Christian von Ehrenfels, an Austrian psychologist, remarked that in this description of the field many visual characteristics such as round, angular and slender were omitted. For their occurrence neither single stimuli nor mere sums of such stimuli can be made responsible. This becomes particularly obvious if, in a given case, all individual stimuli are changed in the same proportion. The characteristics in question are not affected by this measure. When presented in a changed colour, in a different place or in another size, an object remains about as round, angular or slender as it was before. Von Ehrenfels added that in the dimension of time, analysis meets with the same difficulty. Thus, in music the major and the minor characteristics of melodies belong to the melodies rather than to individual tones. Since visual shapes (Gestalten) are the most obvious instances of such phenomena, Ehrenfels called the whole class Gestalt qualities.

But analysis in the customary style also ignored the entities which have such attributes. In vision, for example, retinal stimuli represent a mere mosaic. And yet visual Ehrenfels qualities are for the most part attributes of specific objects such as things and figures. What is the nature of these units? Some authors maintain that the units are established by intellectual processes. However, while intellectual activities may interfere with given objects, there is no empirical evidence that such activities form the objects in the first place.

In 1912 M. Wertheimer was led to a much more radical solution of the problem. He denied the existence of sensory elements as parts of perceptual experience. According to him, the nervous system tends to give a unitary answer to the total stimulating situation with which it is confronted at a given time. But far from being uniform, this answer is for the most part quite articulate. In certain areas the unitary character of the response is greatly enhanced, while at the same time these areas are relatively segregated from their environment. Thus, things, figures,

etc., originate. In the temporary dimension the same happens: from the unitary course of experience particular events tend to be segregated which are to this extent analogous to objects. Such events and objects again need not be uniform. Just as they are relatively segregated members of the total field so they may have parts of their own. This term parts, however, now has a particular meaning. Genuine parts of a sensory field or of its objects involve, qua parts, inclusion in the larger units in which they lie. They are experienced as referred to these larger entities. They must also be distinguished from the arbitrarily chosen elements into which traditional analysis would split sensory experience. From the new point of view, analysis is justifiable only if it deals with the genuine parts of a field.

In Wertheimer's writings the specific units or entities which appear in a field are called Gestalten. Although this terminology corresponds to common usage in German it greatly disturbed psychologists in England and in America who translated Gestalt as "shape" (which it may also mean in German). In Gestalt psychology, the substantival connotation of the term plays a much more important part than its adjectival meaning, which refers to shapes rather than to the entities which have shapes. In English, the process of articulation is commonly called organization of the field, a term which may also be used for the outcome of the process. According to the dictionaries, the word "structure" has about the same two meanings as Gestalt has in German.

Although the stimuli which impinge upon sensory surfaces constitute a mere mosaic, there are always factors in this mosaic which give the process of articulation a particular direction. These factors are the formal relations which obtain among the stimuli, such as, for instance, their proximity in space and in time, the degree to which they resemble one another, etc. Other conditions being equal, organization tends to form compact and more or less homogeneous structures rather than widely scattered and heterogeneous units. Again, the process is likely to segregate objects with smooth contours rather than irregularly shaped entities.

From the basic conceptions of Gestalt psychology a great many specific investigations and theoretical discussions developed. Particularly interesting are those in which the new point of view was defended against a rival thesis: the thesis that, after all, elementary sensations are the real material of the sensory world, and that only learning about the unitary objects of the physical and practical world makes things out of sensory atoms. This theory cannot explain the fact that the outcome of sensory organization may be at variance with our knowledge of objects in the practical sense. Thus, well-known objects are not seen, and strange things are seen instead, when the principles of organization favour existence of the latter. Experiments have shown that previous experience has a certain influence upon the organization of given fields. But far from proving that learning fabricates things out of sensory elements, these experiments demonstrate only that familiar forms of organization tend to modify subsequent processes of articulation.

Organization ought not to be interpreted as a mere formation of agglomerates. In the first place, the characteristics of things are generally affected by their inclusion in larger organizations. In other words, organization involves interaction. Such interaction seems to explain colour and brightness contrast, most so-called optical illusions and, also, several perceptual constancies. As an example: When the illumination of an object and of its immediate environment changes, stimulation in the area of the object and its background is correspondingly altered. Nevertheless, the colour of the object tends to remain virtually unaffected. According to the Gestalt psychologists, this constancy of object colour is brought about by interaction between the object and its environment. They claim that, under the circumstances given in a case of constancy, this interaction operates against the effects of changed local stimulation, and thus exerts a compensating influence.

In the second place, organization gives its products characteristics of their own, such as the Ehrenfels qualities. It is, however, not only segregated objects as such which exhibit particular characteristics of this kind. The same holds for their parts. Thus, a certain point in an object is a corner only within this larger unit, a line is a boundary only with reference to a segregated area, etc. One particular characteristic of this class has become famous by an investigation of E. Rubin (1921). He called attention to the difference between figure and ground, between the substantial appearance of objects and the looseness of their homogeneous environment. Equally important is A. Michotte's discovery (1941) that, under certain conditions of successive stimulation, causation is directly experienced as a characteristic of organized developments.

Organization in Physics and Physiology.—Since, as a rule, perceptual organization does not originate within experience, it must be processes in the sensory nervous system which are responsible for the formation of perceptual units, for the change of their characteristics by interaction and for the emergence of Ehrenfels qualities. Thus, Gestalt psychology is under obligation to show that organization occurs in the realm of physical facts; that some particular facts of this kind occur in the nervous system; and that physiological organization in this sense actually underlies all instances of organized experience. As to the first point of this program, such eminent physicists as C. Maxwell, M. Planck and A. Eddington have sometimes clearly stated that a purely analytical approach may not be able to do justice to all phases of physical nature. Actually, whole sets of physical processes are never treated in what could properly be called an analytical fashion. The epistemology of physics has merely failed to recognize this fact, although it is implicit in the physicist's own work. It was first made explicit by W. Köhler (*Die physischen Gestalten in Ruhe und im stationären Zustand* [1920]). He showed that all instances in which physical materials or processes distribute themselves under certain limiting conditions fulfil the principal criteria of organization. For instance, if water streams through a system of interconnected pipes, the flow in each pipe depends upon the flow in all other pipes. For, if an obstruction is introduced in one pipe, the flow in the others is immediately affected. Similarly, if an electric current flows in a network of wires, the self-distribution of this flow is maintained in the system as a whole. Any local change of conditions is at once reflected in a redistribution of the current everywhere. In other words, a physical self-distribution is relationally maintained and relationally determined. This is clearly shown in the mathematical expressions which serve to describe such a process. In any formula which refers to local events within the total distribution, these events are related not only to corresponding local conditions but also to the conditions in all other parts. More particularly, the determining conditions appear in the form of their ratios so that physical self-distributions remain unaffected if all local conditions are varied in the same proportion. Obviously, this agrees with the criterion which Ehrenfels used when he first called attention to Gestalt characteristics.

In connection with psychological problems, it must be emphasized that physical organization is not restricted to self-distributions which occur in conducting networks. On the contrary, this concept applies most readily to instances in which processes distribute themselves within continuous media.

In trying to indicate what particular processes actually underlie organized experience in perception, Gestalt psychologists propose a change in neurological theory. They do not believe that brain function is limited to the propagation of nerve impulses along separate fibres. Köhler developed a theory of vision according to which organized function in the brain is a matter of electric currents. These currents are supposed to distribute themselves in the brain tissue as a continuous volume conductor. The theory is supported by the fact that organized processes in perception have specific aftereffects which can readily be explained on this ground. The general direction in which Gestalt psychologists attempt to develop neurological theory is indicated by the term "isomorphism." The term means that the facts of organized experience and the brain processes which underlie these facts have precisely the same structures. It would, for instance, follow

that to any symmetry in perception there corresponds the same symmetry in the functional interrelations of the underlying process, that segregated units in perception are associated with functional units in brain dynamics, etc.

Organization in Higher Mental Processes.—An early extension of Gestalt psychology beyond the field of perception referred to such concepts as memory traces, association and recall. This development was natural because, when experiences are reactivated in memory, they are on the whole organized in the same sense as are the facts of perception. Gestalt psychology assumes that memory traces are direct products of the processes which underlie primary experience; in other words, that human experience writes down its own history in the nervous system. In the course of time, however, the traces are supposed to undergo changes as a consequence of their inherent dynamics. Interaction within the realm of traces seems to be of the same kind as that which is responsible for primary organization. Any condition which makes for particular clearness in perception also favours retention in memory, and any factor by which clear segregation in experience is impaired strongly operates against recall. This thesis has been amply verified. It has also been shown that the concept of association by contiguity must be given a new interpretation. According to classical association theory, the connection between remembered items is quite analogous to the way in which places are connected by roads, or objects, say, by strings; *i.e.*, the connection as such is assumed to be indifferent to the nature of the connected items, and vice versa. Gestalt psychology maintains that associations are after-effects of the specific interactions which occur in primary organization. From this point of view, associations must depend upon the characteristics of the items in question because all interaction is a function of the nature of the interacting objects. More particularly, the factors which make for strong perceptual organization of items in pairs must at the same time be factors which favour strong association. Experimental tests have corroborated this conclusion.

A similar reasoning has been applied to the concepts of recognition and recall. Facts in present experience reactivate facts of the past in a highly selective way. It seems that recall begins with a process in which a present experience makes contact with the trace of a similar past event. The way in which similarity here operates as a selecting factor is comparable to the fashion in which resemblance makes for specific organization in perception. From this the conclusion is drawn that recall is initiated by a fact of organization in which a new process interacts with a trace of a similar event in the past. Thus, perception, retention, association and recall are given a unitary interpretation.

The most important extensions of Gestalt psychology refer to higher mental processes. Much in contrast with the view which scientists have of their subject matter, the psychological field exhibits many phenomena of experienced nexus. David Humes's statement that "all events seem entirely loose and separate" does not hold in psychology. According to the German philosopher W. Dilthey, all awareness of relations, but particularly of dynamic relations, proves conclusively that connections among experiences may themselves be experienced. Moreover, such connections tend to have the character of being understandable. When two tones of sufficiently different intensity are given in succession, there may be immediate awareness of the fact that the second tone is louder or softer. This relation is experienced not as a third thing by itself but as being necessary in view of the nature of the tones. In a similar way an emotion is felt to be the adequate and understandable answer to its object; a conclusion emerges as following from its premises, etc. As interpreted by Gestalt psychologists, this means that not only in perception, but also in many other psychological situations, causation is directly accessible to observation, and that it then proves to be identical with the fact that the nature of a given situation requires a certain event to happen. Gestalt psychologists can, therefore, say that in experience certain occurrences "make sense" while others fail to do so. With a more subjective expression, they claim that man may have insight into the "ought" of facts. Thus, in Gestalt psychology, the term insight does not refer to a mental power, nor is it necessarily related to new discoveries. Rather, it is a descriptive term which designates a peculiarity of certain forms of experienced nexus.

In this fashion, the Gestalt psychologists relate the concept of value to that of organization. For it is only within organized mental situations that the phenomenon of requiredness is experienced. The school concludes that ethics, aesthetics and logic deal with, and systematize, principles of requiredness which are implicit in experiences of nexus, but are, in common experience, blended with merely factual admixtures.

On such grounds, Gestalt psychologists have begun to investigate learning and thinking as facts which are directly related to organization. Learning, they declare, is often much less an acquisition and retention of given contents than a development of new contents; namely, of new structures in perception and conception. It is not, of course, denied that learning in this sense involves retention of the new structures. But it is stressed that, before the question of retention is raised, the psychologist ought to realize precisely what is being retained. Some theories of learning ignore the organization which given materials tend to undergo when we learn something about a situation. Often, this is the most important achievement in learning, and without it retention would be of little avail.

M. Wertheimer and K. Duncker applied these concepts to the problem of productive thinking. In such thinking a material and a goal are given while the right way from the situation to the goal is not yet available. With sufficient motivation, such a situation tends to reorganize itself so that either the given material changes its structure or the goal is seen in a new light. As a result, relations which played at first no part in the situation may suddenly become entirely obvious. With their appearance the principle of the solution often emerges. To take one of Wertheimer's examples: The task of computing the sum of the terms of an arithmetic series will be greatly facilitated if the even progress of the series in the ascending direction (*i.e.*, the original structure of the material) is replaced by the conception that from the two ends of the series toward the middle the terms increase and decrease at the same rate. Once this is seen, the series readily splits into a known number of quantitatively equivalent pairs of terms, and the result of their sum can be directly found by multiplication. It will be seen that in productive thinking of this kind the reorganization of the field as a whole and the discovery of the main principle of the solution precede the recognition of any particular steps in which the actual solution is eventually realized. Measures of detail are taken only as required by that principle, and in this sense the solution is found "from above" (Wertheimer). In this respect, the Gestalt psychologists' interpretation of thinking differs widely from that given by associationists, who regard both the concept of organization and that of requiredness with suspicion, and interpret the course of thinking "from below"; *i.e.*, as a play of associations which, in conjunction, happen to give the whole solution. From the point of view of Gestalt psychology, it remains to be seen for what reasons problem situations tend to reorganize themselves in more or less adequate directions when the motivation is sufficiently strong.

SOCIAL PSYCHOLOGY

Social psychology deals with those elements in the ideas, emotions, attitudes and habits of individuals which derive from, and relate to, the fact that man lives in social-cultural relations with his fellows. It studies the behaviour of individuals in so far as their behaviour stimulates others or is itself a response to the behaviour of others. Two main areas of interest emerged in this field: One has to do with the place of social-cultural influences in the rise and functioning of the personality (*q.v.*); the other has to do with the mass or collective aspects of man's thought and conduct.

The Social-Cultural Genesis of Personality.—One basic concept of social psychology, especially as it relates to the development of the personality, is *interaction* or the *social act;* that is, an act which is not completed without the intercession or qualification by the act of another. The earlier systematic psychologists usually took the view that the fundamental habits and thought patterns of the individual are built up, through learning, on the basis of innate neuromuscular potentials, including the drives, and that only later does the individual add social features to his mental and behavioural repertoire. This atomistic viewpoint is rejected by the interactionist school. It agrees with individualistic psychology regarding the importance of biologically inherited drives, of neuromuscular maturation and of learning. But its central theme is that the individual is more or less socially and culturally conditioned at every point from birth on.

This position is defended, first, on the ground that man as a member of the mammalian family is born into a social situation, involving at least the mother and the infant himself. Second, in the early months and years the new member is socially dependent on other members for his food, shelter and bodily protection. Third, within this interactional framework even strictly individualistic, biological reactions such as concern elimination, posture, locomotion and sleep become socialized or conditioned through the tuition of others. In fact, within this social matrix all the basic skills and knowledge develop. The internal organization of stimulus-response patterns (that is, perception, reasoning and concept formation) are all affected by the interplay of the growing child and those who surround him. And in this development communicative as well as overt physical interaction has a part.

Not only is the social impact, as such, basic, but the parents and others bring to the child their culture patterns. These consist of the more or less standardized and expected ideas, attitudes and habits which serve to direct the child's learning and to provide him the content and meaning of his varied experiences. Thus, while the fundamental drives and mechanisms of adjustment are derived from species inheritance, the learning process is social, or cultural, or both, at every step of the way.

The interactionist position derives from the work of J. M. Baldwin, C. H. Cooley and especially George H. Mead and John Dewey. According to Baldwin, the self or personality develops from the give and take of the infant and child with those about him. This he termed the "dialectic of personal growth," operating through imitation, suggestion and accommodation (habit). Cooley's phrase "the looking-glass self" summarized his view that self-feeling, illustrated in pride or mortification, rests upon one's image of himself as he has derived it from others.

It was George H. Mead in *The Journal of Philosophy* (1922) who stated the process of personality formation in interactional terms without positing inherited social instincts. In his words: "The self arises in conduct when the individual becomes a social object in experience to himself. This takes place when the individual assumes the attitude or uses the gesture [or word] which another would use and responds to it himself or tends to so respond. . . ." The growing child introjects into his own stimulus-adjustive-response system the reactions of other individuals with reference to him. He calls out in himself their attitudes and responses as well as his own toward himself. This duplication of the actions of others Mead called role-taking.

At the outset, roles are highly specific. For example, in his play a child may assume the mother's or father's tones, words and actions toward his toys, dolls and his real or imaginary playmates. In his fantasy he may play many parts. At one moment he is a buyer, at another the clerk making a sale; he may be a gangster for a minute and a policeman arresting himself the next. In taking such roles language has a central place. The child talks to himself as others have talked to him.

Yet roles do not remain entirely specific. The repetition of the same or similar drives and situations leads particular roles to become generalized. An early general role centres around his age, status and function within the family. The chief general roles of the adult male in our society are those of husband-father-breadwinner, good citizen and solid churchman.

The social self, however, is not merely a reflection and reorganization of ideas, attitudes and habits which one picks up from others. At all times the drives and action patterns of the individual are present and serve as the dynamic and unique elements in personality. Mead held that these drive-action elements and the specific or general roles together "constitute a personality as is appears in social experience."

If one's ideas, attitudes and habits derive from integrating the roles of others with one's own drive-action systems, it follows that mind itself must be a social product. The chief medium by which mind is built up is communication through gesture and language.

The thinking function arises as the child rehearses and reorders the interactions—overt and verbal—which have gone on between him and others or which he has observed among those around him. Dewey has aptly pointed out the dramatic (that is, interactional) character of our mental processes. And the investigations of many child psychologists give concrete evidence of the social foundations of the sense of self and of the thought processes.

Language as the vehicle of communication sets up expectation or incipient action in the person spoken to, and likewise, in terms of introjection, anticipatory response patterns in the individual speaking. Meaning depends on one's perception and conception of the object of communication as it functions in the other's experience as well as in his own. So, too, the respondent must perceive or conceptualize the idea as it operates in the speaker. As Dewey says in *Experience and Nature* (Open Court Publishing Co., 1925): "To understand is to anticipate together, . . . to make a cross-reference which, when acted upon, brings about a partaking in a common, inclusive, undertaking." In short, meaning always falls within the self-other configuration.

Many social interactionists tended to neglect the place of the content of ideas, attitudes and habits in personal development. But this need was met chiefly from Freudian psychologists in collaboration with cultural anthropologists.

The aim of the culture-personality studies is to compare critically the way in which the basic drives and capacities of the new generation are moulded by culture—chiefly at the hands of family members and primary groups; that is, to modify and elaborate them into adult motives, roles and other elements of the self. For example, certain studies show that the masculine-feminine roles as defined in western culture are quite differently organized among other peoples. So, too, co-operative-affectional in contrast to conflictive-aggressive patterns differentially affect personality formation. Among primitives like the Arapesh, Zuni and Hopi, and among certain Christian sects, such as the Amish and Mennonites, the individual is trained from birth on to be sympathetic and helpful of those around him. Rivalry and personal push are punished. The result is a rather quietistic, mild and nonaggressive person. In contrast, the highly competitive societies like those of the Kwakiutl Indians or the modern United States induct their children into a set of values and habits which stress intense interpersonal struggle, ambition for status and monetary rewards. Or, in militaristic countries like imperial Japan and nazi Germany, the child, especially the male, was brought up in aggressive, conflictive patterns of thought and action.

This does not mean, of course, that aggressive responses are entirely lacking among the Pueblo Indians or among the pietistic sectarians. But they are suppressed and sublimated. Yet among the Zuni vicious gossip provides an outlet for interpersonal antagonism. And some, at least, of the U.S. quietistic sectarians have been known for their sharp competitive business sense.

These comparative analyses show that personal sense of security, presence or absence of inner tensions, the emphasis on introvertive or extrovertive values and activities and other elements of the personality will be greatly influenced by such differentials in training.

A provocative approach in this field was that of A. Kardiner and R. Linton, who examined both primitive and civilized societies in an effort to discover "a group of nuclear constellations in the indi-

vidual" designated as "the basic personality structure." By applying psychoanalytic concepts to known differences in early child training, especially in the mother-child, father-child and sibling interactions, they traced the integration of ideas, values, attitudes, and habits which form the distinctive modal personality features of all members within any particular society-culture milieu.

The co-operation of workers in psychology and anthropology in tracking down the cultural sources of personality differences marked a step forward toward a science of personality. But there remained many unsolved problems of data, analysis and interpretation. No theory of modal or basic personality for all members of a given society can get around the solid facts of individual variation and uniqueness. These differences are based on biological variability as to drive, emotion and intelligence potential, on deviations in acquired skills and knowledge and on variations in interpersonal conditioning at all points. As to the latter, it can be shown that not all social learning is necessarily culturally controlled or directed, unless culture and all interaction are defined as completely synonymous. There is, especially in the early years, a good deal of social learning which occurs outside the framework of the cultural norms and expectancies, and this learning plays a part in the formation of the personality.

Collective Psychology.—Collective psychology deals with group behaviour, in small as well as larger aggregates such as is found in crowds and audiences, in responses to changes in fashion, in public opinion and propaganda and in various manifestations of leadership. However, there is no special psychology of so-called crowd mind or collective consciousness.

The interactions of individuals in small groups has been studied in order to get at social behaviour which involves, among other things, dominance-submission relationships, degrees of conscious intimacy or hostility among group members, and objects of common or different identification. It is often assumed that generalizations derived from the study of small groups may be applied to similar activities in larger groups. This assumption, however, had not been completely proved at mid-20th century.

Turning to the larger aggregates, a crowd is a relatively temporary congregating of interacting individuals in a limited space. Its typical spatial arrangement resembles the disposition of iron filings around a magnet. There is a centre or focus of attention around which individuals stand or move in varying degrees of verbal, auditory and bodily participation. Unlike the usual face-to-face interactions, the interstimulation of the crowd members is of shoulder-to-shoulder kind.

As to responsiveness, crowds may be further defined as passive or active, the former illustrated by a transitory grouping of pedestrians to watch a dogfight, the latter by the intense emotions and agitated actions of a crowd celebrating the news of a victory, taking part in a lynching or fleeing a fire in panic. Psychologists have given most of their attention to the action crowd.

The principal psychological characteristics of the individual in an action crowd are, first, the expression of strong emotions of love, hate and rage, associated with the basic values of life and security; *e.g.*, bodily survival, sex, property, race, religion, class status and national honour. Second, there is intense ego-expansion in terms of all-or-none, absolutist convictions. Third, a sense of self-righteousness overrides one's habitual sense of guilt and shame. Also, the crowd-man quickly identifies himself with some in-group which stands opposed to some out-group.

Men under these conditions release hidden and suppressed motives. In so doing imitation (*q.v.*) and suggestion (*q.v.*) play a large part, especially in adding a crowd-stimulus or social facilitation to that of the deep-seated drives. Suggestibility and imitative training in copying and conforming to others lead to the inhibition of critical attitudes in favour of doing unwittingly what those around one are doing. There also develops a strong sense of safety in numbers. The prestige and power of numbers fosters anonymity and the "impression of universality." Finally, long training in deference and obedience to leaders and symbols of authority makes for adherence to the emotion and action stimulated by the leader of the crowd. Such interactions as rhythm of bodily movements, whispering, shouting and pushing all add to social facilitation. In short, there is a summation of primary and crowd stimuli which impels the mass along its particular course of action.

It is often said that the crowd-man loses all morality and decency. By traditional standards this is correct; but the self-righteousness of mobs is well known. There arises a primitive morality of survival and group solidarity which temporarily replaces customary conscience. This rudimentary morality even persists, when the violence is over, in the rationalizations which people give for their participation in a mob or panic.

However, a crowd does not act entirely outside the framework of culture. Clearly all kinds of mobbish behaviour have their roots in the faiths and values of the participants. On the American frontier the lynching of cattle thieves was an accepted form of social control. So, too, the lynching of Negroes in the south. Even the periodic mass violence of race and religious riots in the United States, the near east and in India have their original motivations in the values of race, class and religious differences.

An *audience* is an institutionalized crowd which meets for a more or less specific purpose at a predetermined time and place. The polarization and interactional forms vary with the kind of audience. Most audiences may be classified as information-seeking, recreation-seeking and conversional. The first is characterized by a rational aim and function; the other two are loaded on the side of emotion and action.

The psychology of the audience is revealed, first, in the preliminary tuning or prior stimulation, as through advertising and conversation designed to draw out the participants. Second, there are some initial interactions at the time the group forgathers but before the central function begins. Third, the speaker or performers must gain rapport or attention to bring about close identification with the activity. In the informational audience this tends to be by means of logical imagery and abstract ideas. In the other two it is usually a mixture of the rational and the irrational.

Fashion is a prevailing usage, mode, style or manner of expression or presentation of certain cultural elements which are open to, or subject to, relatively rapid change. Fashion operates chiefly with respect to clothes, architecture, furniture and modes of transport and communication. *Fad* refers to more superficial, more fleeting and more bizarre forms of such things as decorations or slang. The word *craze* is usually applied to highly transitory, though often widespread, forms of bodily activity, such as certain dances, miniature golf or unconventional gestures or postures.

For the individual, being in fashion provides a curious but pleasing mixture of personal distinction and group conformity. It at once sets one apart from the masses but gives evidence of adherence to one's class by virtue of others also following the fashion parade.

To understand public opinion the meaning of both "public" and "opinion" must be clear. As an adjective, "public" means that which is known, actually or potentially, to all members of a community. As a noun it refers to a relatively large aggregation of persons, not necessarily contiguous, loosely associated together by some common interest. There is not just one public, the political, but actually various publics concerned with any focus of wide community interest. "Opinion" is a judgment or belief based admittedly on ground short of full proof or certainty. Public opinion, then, consists of judgments about some topic of interest in a given public at some particular time and place. It is usually expressed in words and is often related to deeper and more permanent attitudes and values.

The crucial matter of public opinion is its formation and change. While there are some situational variations, the formation of public opinion follows certain stages through time. The first is the rise of an issue or problem confronting a given public. The second is the conversation and discussions by members and leaders who try to define the issue more sharply and perhaps offer some tentative solutions. The third stage appears with the taking of definite positions as to the nature of the solution and the means of attaining it. The final stage is the arrival at consensus. This may mean a compromise of opposing views or it may mean the

acceptance by the majority of the views of one side. Consensus may be expressed by written memorials to legislative bodies or executives, by public opinion polls and by legal voting. The overt execution of any decision belongs to action programs and lies outside the strict process of opinion formation.

In democratic societies the formation of public opinion follows this general pattern. Under totalitarianism, opinion formation tends to be restricted to the élite of the dominant party or to party members only. It is not a function of members of the wider community or society. However, this does not mean that amorphous and less vocal publics may not influence opinion formation at any step. Dictatorial governments usually "have their ears to the ground" though they may, by propaganda, attempt to determine the nature and direction of any popular ground swell.

In contrast to conditions in simpler, rural societies, public opinion in highly industrialized, urban societies raises many questions of manipulation and control by political and special interest pressures.

Under such modern conditions propaganda and censorship have especially important bearings on the formation of public opinion.

Propaganda is the deliberate use of symbols, chiefly through suggestion and persuasion, with a view, first, to changing and controlling opinion, attitudes and values, and ultimately to altering overt action along predetermined lines. Also propaganda may be open and obvious to the recipient as in advertising or a public health campaign, or thoroughly hidden and disguised as in the promotion of a revolution or a war.

The essential mechanism of propaganda is suggestion, the aim being acceptance, not logical reflection. Yet in analyzing propaganda it is necessary to know the motive and purpose of the operator, the symbol content he uses and the responses of his would-be recipients in order to find out to what extent their opinions, attitudes and habits have been altered.

Successful propaganda must be related to motivation and culturalized attitudes and habits. While the particular situations vary, among the more common facts which the propagandist must bear in mind are these: (1) It must be linked to basic motives of those to whom it is addressed; (2) the primary appeals should be emotionalized symbols of promise and satisfaction; rarely, and for selected audiences, may rational appeals be used; (3) both the issues and the proposed solutions must be simplified; the promotional artist deals in whites and blacks, in good and evil, not in the intellectual elaboration of a topic; (4) systematic and rhythmic repetition of these few and simple elements is usually effective; (5) innuendo, indirection and implication are frequently preferable to direct statement, especially in the early phases; (6) once the desired motive and bias are established, blunt, declarative and unsupported statements may be used as well as exaggeration, startling accusations and outright falsehood; (7) finally, short-run propaganda may be directed to all age groups, but that designed for more complete and lasting indoctrination should be directed to children and youth. They are the most suggestible since their basic values and attitudes are less deeply rooted.

The tactics just cited deal with the intent and stimuli of propaganda. Accurate knowledge about the effects on those to whom it is directed is more difficult to secure. However, we have some information on the influence of deliberate planting of content in newspapers and of exposure of young people to selected propaganda through the films or radio. The results show that within the limits of previous social-cultural learning changes in opinions and attitudes can be effected. There is little if any valid data on the influence of such experimental propaganda on later overt conduct.

Yet, it would be a mistake to hold that propaganda is ineffective. Campaigns to repeal the Corn laws in Britain, the abolitionist, prohibition and populist movements in the United States, Communist and fascist agitation and its use in war—all exemplify its importance.

Leadership is a universal feature of social interaction. It means the determination of certain responses of another or others in line with the leader's wishes.

Attempts to classify dominant individuals are common but difficult to support objectively. Some writers take their cue from differences in leadership role and status under varying situations. There is the dual classification of leaders into executives, or men of action, and thinkers, or men of thought. Some writers require more than two categories, as in the division into executive, dominant, persuasive and expert leaders, or into headship, voluntary leadership and status forms of dominance.

Classifications which attempt to get at psychological characteristics also face difficulties. Followers of Carl Jung's typology often divide leaders into introverts or extroverts; others use Ernst Kretschmer's schizothymes or cyclothymes. But most attempts to use these types empirically lead to further assumptions of mixed types as well.

So, too, psychologists who approach personality from the angle of specific traits and attitudes have trouble in deriving any common clusters of these elements which might characterize all leaders, or, for that matter, even those within such social categories as those noted above. One writer tabulated the 79 distinct traits cited in 20 separate studies of leadership. Of the total list, two-thirds of the traits were named but once, and only 5% had as many as four traits in common. The most common trait cited (in ten studies) was intelligence. Initiative was noted by six; extroversion and sense of humour, each by five; and enthusiasm, fairness, sympathy and self-confidence, each by four. Much careful research needs to be done before any satisfactory generalizations can be made about the psychological traits or types which characterize the dominant individual.

Regarding the relation of psychological characteristics to occupational or other social roles, there is some evidence that men of introspective, introvertive make-up tend to be more successful in science and the arts and that out-going, extrovertive persons are more successful in administrative roles. But cultural expectancies and differential circumstances may serve so to disguise the deeper motives, attitudes and values that any one-to-one correspondence of psychological make-up and social role is difficult to find. Men of the introvertive order are found in executive positions. Furthermore, since mixed types are probably more common than so-called pure types, most individuals may adapt themselves to one role or another without undue inner tension.

The qualities of leadership are definitely affected by the ideas and reactions of followers. The latter invariably attribute certain ideal qualities and powers to the leaders. This sets up expectations as to conduct on the part of leaders which they must follow, or seem to follow, if they would retain their dominance. This projection of ideal qualities is doubtless the reason why the traits of leadership are nearly always put in laudatory, admiring terms. Negative and derogatory traits seldom appear in listing the characteristics of leaders.

Methodology.—Though by no means well-ordered as a logical system, social psychology has developed points of view, hypotheses and methods of empirical research which, in time, should produce a body of systematic knowledge adequate to provide predictions and control of human conduct.

The principal scientific approaches to social psychology are the case- or life-history method and the use of statistical techniques. An attack on the problems in this field by strictly experimental methods has only recently begun.

The aim of the life history is to discover and analyze the social-psychological processes, operating through time, which cause the emergence or modification of roles, statuses, traits, opinions, attitudes, values and other elements of the personality. In some studies there is an attempt to reconstruct the whole course of personality growth on the assumption that this will permit a fuller understanding of adult behaviour.

The data for the case study are protocols of oral interviews or formal and informal writings of the informant. Interviews may be prolonged in time and demand special skills, as in psychoanalysis, or may be relatively short. Free-association techniques or direct questioning may be used in either to elicit forgotten and unconscious memories necessary to reconstruct the genesis and meaning of the factors in personality growth. Formal written reports may

be secured by questionnaires or outlines likewise designed to bring out memories of past events. Informal written documents consist of free-flowing autobiographies, letters and diaries or the protocols from projective tests.

The life history is open to question, first, in terms of the assumptions that this device will lay bare the genetic and functioning processes; second, as to the validity of memories on which the data depend; and, third, as to the standardization of procedures, since the difficulties of communication of meaning unwittingly qualify the responses of both informant and observer. Fourth, generalizations are often made on too few cases and with complete neglect of sound sampling.

Yet the case study provides an understanding of motivation and meaning which is often not obtainable through so-called more exact techniques. A combination of statistical and case methods, as in some of the projective techniques (*see* PERSONALITY), should, in time, contribute valuable data to a science of social psychology.

The quantitative study of personality derives from the measurement of intelligence. Taking their cue from mental testing, psychologists and sociologists developed a large number of questionnaires and scales in an effort to measure the manifestations of personality by tapping a wide variety of traits, attitudes and opinions. Usually there are a series of statements arranged in such form that the respondent may mark his agreement or disagreement and perhaps the intensity of his attitude toward each item. An index is then determined by summation of the separate responses or by using such measures as the standard deviation of the distribution. However, the problems of developing equal and interchangeable units on the scale and of composing the scale so as to measure one dimension or cluster of traits, attitudes or opinions at a time have not yet been satisfactorily solved.

While the more adequate scales are statistically fairly reliable, validity is frequently neglected. The basic test of validity is a high positive correlation of measured trait, attitude opinion or value with overt behaviour. All too often it is not clear just what outside criteria, if any, were used to validate a questionnaire or scale.

Although public opinion polls and market analyses usually handle the matter of sampling reasonably well, most studies of traits and attitudes do not. Almost all of them use high school and college student populations, not adults outside. Even so, there is seldom any concern with the representativeness of the sample of this particular universe.

Both from the standpoint of contributing to a scientific knowledge of total personality and of perfecting instruments for predicting specific behaviour, the tests of motives, attitudes, opinions and values have much ground to cover. Yet, with more careful attention to matters of units, reliability, validity and sampling, we may expect, in time, a body of substantive objective generalizations in social psychology.

PSYCHOPHYSICS, the science that deals with the determination of the relation between the mental and physical worlds, or, more specifically, of the relation between sensation and its stimulus.

The word is generally used with reference to the quantitative determination of the latter relationship.

History.—Psychophysics was established by Gustav Theodor Fechner (1801–1887), who coined the word, invented the three fundamental methods, conducted elaborate psychophysical experiments, and began a line of investigation that still persists in experimental psychology today. Fechner's classical book, *Die Elemente der Psychophysik* (1860), may be looked upon as the beginning, not only of psychophysics, but also of experimental psychology (*q.v.*) itself. Fechner, trained in physics, became interested in his later life in metaphysics, and cast about for a way of relating the spiritual to the material world. He hit upon the notion of measuring sensation in relation to its stimulus. Ernst Heinrich Weber (1795–1878), the physiologist, had discovered that the just noticeable differences between the intensities of sensation always bore, when stated in the increment of stimulus necessary to produce such differences, an approximately constant ratio to the total magnitude of the stimulus. This fact, properly speaking, is Weber's law: if two weights differ by a just noticeable amount when separated by a given increment, then, when the weights are increased, the increment must be proportionally increased for the difference to remain just noticeable. Fechner chanced upon Weber's law and undertook to use it for the measurement of sensation. If R be the stimulus (*Reiz*), and S be the resultant sensation, and Δ signify an increment of either, then Weber's law becomes $\Delta R/R=a$ constant, for the just noticeable difference. Fechner went further and assumed that all equal increments of sensation must be proportional to the same ratio, $\Delta R/R$, that is to say, $\Delta S=c\Delta R/R$, where c is a constant of proportionality. If this equation is integrated, if R be measured in terms of the threshold stimulus (the value of stimulus at which S is zero or just ready to appear), and if the constant be changed to k for common logarithms, we have $S=k \log R$.

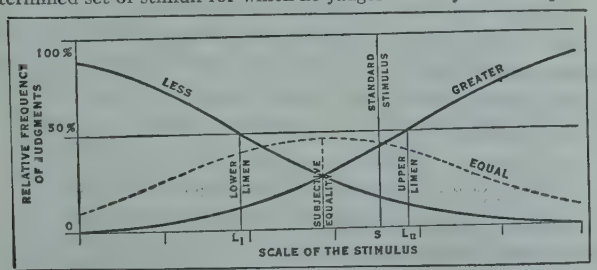
This particular formula Fechner named Weber's law, although it is really Fechner's law and is thus sometimes called the Fechner-Weber law. It expresses the simple relation that the magnitude of a stimulus must be increased geometrically if the magnitude of sensation is to increase arithmetically. For Fechner it meant that the relation between the spiritual and material worlds is statable, and that there is therefore only one world, the spiritual; but for physiologists and for many philosophers it meant the measuring of sensation in relation to a measured stimulus, and thus the possibility of a scientific quantitative psychology. Fechner got his conception of psychological measurement from Herbart, but he was really refuting Herbart in demonstrating that psychology can be experimental.

Fechner's original work stimulated much research and much controversy. It was argued against him that it is introspectively obvious that sensations do not have magnitude (the quantity objection), that "a scarlet is not just so many pinks." This difficulty was met by the Belgian, J. L. R. Delboeuf (1831–1896), who developed the concept of the sense-distance, holding that sensations, although not complex magnitudes, are separated by variable distances which can be compared as "greater," "equal," or "less," the three categories of judgment which the psychophysical methods require. In Germany, Georg Elias Müller (1850–1934) undertook an elaborate criticism of Fechner and an extension of his work. In America, E. B. Titchener (1867–1927) made a historical and practical exposition of psychophysics in the second volume of his *Experimental Psychology* (1905). More recently F. M. Urban, then also in America, improved one of the methods and developed the concept of the psychometric

function. Other well known psychophysicists are W. Wirth in Leipzig, and William Brown and G. H. Thomson in England.

Limens.—Psychophysics makes extensive use of the concept of the threshold or limen, of which there are two kinds. (i.) The *stimulus limen* is that value of stimulus which terminates a sensory continuum. The visible spectrum is limited by a stimulus limen in the reds (*c.* 800$\mu\mu$ wave-length of light) and another in the violets (*c.* 400$\mu\mu$). Tones range between the limen for the lowest audible tone (*c.* 16 vibrations per sec.) and the limen for the highest audible tone (*c.* 20,000 vs./sec.). The stimulus limens for intensities of weights, sounds, brightnesses, and other sense-qualities have been determined, but depend upon so many factors that no simple statement of their values is possible. Stimulus limens have also been determined for size and for duration. In the case of illumination, the size, duration and intensity of the stimulus are interrelated; a very small stimulus has to be more intense to be perceived. (ii.) The *differential limen* is that difference between two stimuli which marks the boundary between sensed difference and sensed equality. It is often confused with the just noticeable difference, although in fact it is a statistical quantity for the theoretical point between what is just noticeable and what is just not noticeable. In fact both limens are statistical values, for the variability of the conditions of excitation cannot be controlled and what is sensed at one time may not be sensed at another. Hence the limens are averages or mathematically determined points where the sensation is as often sensed as it is not.

Methods.—There are three fundamental methods of psychophysics, all of which Fechner invented. (i.) In the *method of limits* (method of minimal changes, of least perceptible differences) the stimulus is varied serially (usually by discrete steps) until a change is noticed. For example, to determine the stimulus limen of intensity, imperceptible intensities are presented in increasing order until the stimulus is first sensed; then a descending series from perceptible to imperceptible is observed; and finally the results of many such series are averaged. For the differential limen there are always two stimuli, of which one, the standard, is kept constant, and the other, the variable, is altered until a difference between the two appears or disappears, according to the direction of change. Here the limen is the distance from the standard to the average point of change, and there are always both an upper differential limen and a lower, since change can be noticed on either side of the standard. (ii.) In the *method of average error* (method of production) the experimental subject himself changes, by means of appropriate apparatus, the stimulus continuously, usually until subjective equality with a standard has been reached. Since subjective equality is not physical equality, the results yield an average or constant error for the subject and also a variable error about this average. (iii.) In the *constant method* the subject is presented at random with a predetermined set of stimuli for which he judges in every case the presence or absence of sensation or of the difference between the sensations. Because of the variability in the conditions of excitation his judgments are not always the same for the same stimulus, but it is found that, as a difference increases, the frequency with which the difference is perceived increases. When enough judgments have been taken, these relative frequencies can be plotted in a *psychometric function*. The figure shows the case of the differential limen. Reading from left to right, the frequency with which the variable is judged "less" than the standard decreases, the frequency of the judgments "greater" increases, whereas the remaining cases, the equality judgments, are maximal at the centre. The liminal values of the stimulus are taken as those values where the probability of the judgment "less" or "greater" is as likely as it is not, *i.e.*, the points on the scale of the stimulus corresponding to the points where the abscissa for 50% crosses the psychometric functions. The limens are the distances of these values from the standard stimulus (the distances L_1 to S and L_u to S) and one of them may even be negative when subjective equality deviates widely from the standard. Subjective equality is usually taken as the point where the judgments "less" and "greater" are equally likely, *i.e.*, the intersection of the two psychometric functions. It is customary (as in the figure) to fit to the observed frequencies for the psychometric functions smooth ogives of the normal probability integral, sometimes called the phi-function of gamma; but this curve is only an empirical approximation and has no theoretical significance.



Weber's Law.—The Fechner-Weber law implies that all differential limens of intensity should bear a constant ratio to the standard stimulus, whatever its value, and for this reason the psychophysical methods have been used most extensively to test the law and to determine these ratios. In general it may be said that the experiments indicate that the law holds approximately, although not exactly, within the middle ranges of intensity, but not for very small or very large intensities. Thus it appears that the liminal ratio for visual brightness is about 1/100, that is to say, illumination must be increased by 1/100 of its amount for a change to be perceived. The liminal ratio for lifting weights with the hand is about 1/40 and for pressure on the skin about 1/20. For tone the value is about 1/10; and for smell it ranges as a rule between 1/4 and 1/3. *See* DISCRIMINATION, SENSIBLE.

Results.—There is a very large body of quantitative results on liminal determinations. For theoretical purposes the constant method with weights, lifted by the hand, has been most used. The psychophysical methods, however, lie at the basis of nearly all quantitative methods of experimental psychology, especially those that deal with sensation. In its mathematical theory psychophysics is identical with the statistical methods that psychology uses in social measurements and with mental tests, and the boundary between the psychophysical and the statistical methods is thus quite properly becoming dim.

PSYCHOSIS. Strictly speaking, the term psychosis means a state of mind, a concrete psychical process or a mental act; but it is generally used to signify an abnormal state of mind. This definition needs qualification, however, since the technical use of the term in psychiatry is confined to certain forms of mental disorder which can be distinguished from states of congenital mental deficiency on the one hand, and from "borderland" conditions or neuroses on the other. A distinction should be made between "psychosis" and "insanity," which in popular and legal language signifies that an individual, owing to his state of mind, is unable to manage himself or his affairs, is in need of care and control and is not to be held accountable to society for his actions.

Psychosis, on the contrary, is a strictly medical term; it refers to a type of mental illness with certain intrinsic characteristics, assuming various forms, and is the result of a variety of causes. It does not necessarily lead to serious disturbances of behaviour, and there are many individuals who though not insane in a legal sense are nevertheless the subjects of a psychosis.

Psychological Considerations.—Though it is convenient to divide mental disorders into different categories based upon their causation, clinical characteristics or course and outcome, so many transformations of the clinical syndromes occur that no hard and fast division into separate disease entities is possible.

It is desirable to differentiate between leading types of psychoses, and between psychoses and other types of behaviour disorders, especially the neuroses which include those maladaptations known as phobias, hysterias and obsessions. Although both psychoses and neuroses may have some similar features in their historical development and in their dynamic defenses, there are differences in both the quantity and quality of their dynamic systems. The psychotic has ego functions which are damaged in one or more spheres, especially in the ability to maintain object relationships with things or people. Since he cannot cope with his environment, data are falsified in order to obtain some kind of mastery. The neurotic does not grossly distort the facts of the environment but rather tries at first to work out his conflicts within himself and then only secondarily "acts out" his conflict. The neurotic, as it were, remains in touch with people, whereas the psychotic often seems distant, strange or even bizarre. The psychotic often seeks infantile pleasures of a rudimentary, often undisguised, type. He expresses many emotions, especially hostility, more openly than the neurotic. He has less need for defensive refinements or ambivalence (*i.e.*, simultaneous opposing emotions toward the same object). Projecting his own beliefs upon others and impugning improper motives to them is much more common than repression. Anxiety is usually not so well organized in the psychotic and he shows much less shame, guilt and sensitivity about his own or other people's performance. Modulated expression of personal needs, which are compatible with conventional practices, are often lacking in the psychotic, so that he may then be in danger of injury or arrest. The psychotic may exhibit behaviour of infantile origin utilizing archaic language and motility, delusions of grandeur, somatic symptoms, destructive fantasies about the self, other people or the world. Delusional systems and hallucinations are considered to be attempts by the damaged organism at restitution. Incomplete repression often causes the psychotic to be severely distressed by primitive wishes. Under stress the psychotic may resort to gross flight and massive withdrawal including suicide rather than to defensive symptom formation as in the case of the neurotic. It is generally agreed that most persons will exhibit neurotic defenses under stress, especially if that stress is specific for the person concerned. It is also generally agreed that most persons will not utilize psychotic mechanisms except under extremely devastating conditions. Those who employ psychotic defenses under relatively moderate stress are apparently much more susceptible than the nonpsychotic population. It is not certain just wherein this susceptibility lies in spite of many attempts to prove that heredity, constitution, or body-build are the crucial factors.

Groups of Psychoses.—Psychoses are ordinarily grouped into the organic and the functional. The organic psychoses may have many causes (alcoholic psychosis, general paresis, senile dementia) but have one factor in common, *e.g.*, a physical disorder of the brain. The signs and symptoms vary with the amount and distribution of the physical involvement and the individual personality response of the patient. Patients become sad, elated, suspicious or destructive, not only because of the loss of cortical control through loss of tissue, but because of the underlying personality organization. The functional psychoses have come to be regarded as reaction types, ways in which a patient attempts to deal with his problems. The early attempts to create distinct clinical disease entities, which are both chemically and psychologically identifiable, remained unsuccessful in the 1950s, although many workers persisted in this hope. In practice the reaction types seem to have many mixed features if they are carefully studied over a number of years. The manic-depressive reaction is characterized by severe change in mood, possibly alternating at times, with intervals of normality. The process may never recur after a single attack. The schizophrenic reaction-type is likely to be more persistently disruptive of the patient's relations to other people; but optimistic, skilful therapy has repeatedly demonstrated that favourable results are possible, especially if other life circumstances are also conducive to recovery. Other types of functional psychoses are being recognized as more or less related to those two basic forms: schizophrenia with obsessional defenses, pseudoneurotic schizophrenia, depressive psychoses with hysterical defenses.

Complex forms of criminality, and even psychosomatic diseases, may also prove to be related to psychotic mechanisms, but much more quantitative work will be required to demonstrate the relationship of the various factors to each other.

Causation and Treatment of Psychoses.—A psychosis is a disorder of behaviour, and represents a failure of function at the psychological level. Psychiatry (*q.v.*) thus differs in its subject matter from general medicine; the former deals with disturbances in the reactions of the organism as an integrated whole, and the latter with disorders of special systems of organs. Since the behaviour of an individual, whether normal or abnormal, depends upon an infinity of factors—the nature of his life situations, the state of his organism, and the whole of his past history, both personal and ancestral—it is impossible to select one factor as explanatory of the total reaction. The problem of causation in the psychoses is thus dissolved in relativity, and in each case an endeavour is made to seek out, and remove where possible, any factors, either physical or mental, which seem to be exerting an unfavourable influence upon the behaviour.

There is a general tendency to approach the problems of mental disorder from the standpoints of biology, pathology and general medicine, as it is recognized that the psychoses must be the outcome of a malfunctioning organism. Many psychoses, indeed, have definite relationships to diseases of the nervous system and of the bodily organs, as well as to general disturbances caused by infections, exhaustion and drug intoxications. Modern treatment attempts to take advantage of all new drugs or physical methods to the advantage of the patient. The demonstration by Julius Wagner-Jauregg (1917) that malaria could "cure" general paresis, and the addition of dilantin for the control of epilepsy set up patterns which have had numerous progeny. Outstanding was the introduction of insulin as a coma-inducing agent by Manfred Sakel in 1933 in the treatment of schizophrenia and the use of metrazol as a convulsant by Ladislas J. Meduna about the same time (1935) for the same purpose. Although later years of experience greatly sobered expectations of benefit from these methods unless substantial psychotherapy is also done, these methods did have the virtue of stimulating interest in the personal care of the patient. Insulin came also to be used in the less drastic sedative sleep treatment. The older Cloetta-Maier "Dauer-Schlaf" (sleep treatment) never became popular, nor did the newer methods of electrical sleep treatment gain wide acceptance. The most widespread treatment after its introduction in 1937–38 by Ugo Cerletti and Lucio Bini has been electroshock. This proved to be unusually useful in the depressive reaction types, especially in patients in middle life. Unfortunately it is not a cure-all even here. Large daily doses are employed in severe cases. Shock therapy has altered both hospital and out-patient clinic practices considerably, for it makes possible a more economical management of the suffering patient in selected cases.

There are no satisfactory neurophysiological explanations for the changes observed, although the cerebral metabolism and circulation are altered. A number of psychological stresses result from severe physical stress and these may contribute to the therapeutic change. It has been observed over many years that some patients would respond with a renewed interest in living if their life was threatened. Some patients respond to physical illness with increased anxiety and dependence which causes them to appeal for help. If this is available they may progress to an independent status. Others seem to regard the physical threat as a fitting punishment for past wrongdoing and improve rapidly. Another theory is that the old defenses are damaged, thus permitting the patient to learn new ones if the means for this is available at the time. Most therapists believe that psychotherapy is an essential part of the total treatment.

John F. Fulton and Carlyle F. Jacobsen in 1935 reported the behavioural changes in two chimpanzees following bilateral removal of the anterior lobes. The animals operated upon had shown less irritability and over-reaction to frustration.

During 1935–36, Egas Moniz and Almeida Lima performed the operation on human subjects for the relief of severe anxiety states. In succeeding years there was increasing opportunity to observe the after-effects of this operation, which is done principally on schizophrenics who can be characterized in many cases by

loss of interest, energy, initiative, spontaneity and sense of humour, and increasing inertia, vacuity and denial of injury. Much work was done to improve the selection of appropriate patients for the operation and also to alter the operation so that the improvement would be maximal and the damage minimal. There are many different types of such operations without clearly demonstrated superiority of any one of them. The follow-up care after the operation with attention to all of the patient's important problems remains one of the most important elements in the treatment. With increased therapeutic experience and some success in severe cases of functional psychoses came a better balanced and more realistic optimism about the psychological meaningfulness of the organism's abilities to adapt to both inner and outer stresses.

Even though genetic, biochemical, and neurophysiological elements may exert powerful influences on the potentiality for the development of a psychosis and on the capacity for recovery, it has been amply demonstrated that in most patients much improvement is possible by skilful psychological treatment. PSYCHOTHERAPY: *see* PSYCHIATRY.

P.T.A., THE, the common designation of the U.S. National Congress of Parents and Teachers, was founded on Feb. 17, 1897, as the National Congress of Mothers. Later broadened to include both parents and teachers, the organization by 1936 had attracted to its ranks about 2,000,000 adults. Ten years later the membership was nearly doubled, and by 1953 almost 8,000,000 individuals were organized in more than 38,000 local P.T.A. organizations.

With the general objective of uniting "the forces of home, school and community in behalf of children and youth," the P.T.A. carried on programs in many fields of endeavour, such as parent education, health, juvenile protection, music, art, safety, mental hygiene and recreation. The P.T.A. also advocated enactment of measures to provide federal aid to education.

A major P.T.A. project in many communities was the sponsoring of school lunches.

Publications include *National Parent Teacher: The P.T.A. Magazine; National Congress Bulletin; National Congress Proceedings* (annual) and other publications of special interest to members.

Legislation Program.—The legislation program of the P.T.A. as adopted in Sept. 1952 by the National Board of Managers was, in part, as follows:

Federal Aid for Education.—"The federal government should appropriate funds to supplement those raised by local and state governments to provide adequate educational opportunities for all children and youth. . . . Such funds should go to publicly controlled, tax-supported schools only . . . with provisions ensuring . . . minimum federal and maximum local control and encouragement to the states to put forth their best efforts to equalize educational opportunities within their own boundaries."

Child Care Centers.—"Child care centers should be made available to children of employed mothers; adequately staffed and supervised by appropriate agencies; and jointly financed by public funds and parents' fees or by funds from public or private agencies."

Surplus Materials.—"Educational, medical and recreational materials and supplies purchased but no longer used by the armed forces should be released to the proper public agencies . . . for use in developing programs of education, health and recreation throughout the United States."

Library Service.—"Public library service should be extended to all people on an equitable basis with special emphasis on needs in rural areas . . ."

Merit System.—"Child welfare services should be administered by persons qualified to do so. Accordingly we support the extension of the merit system for public employees."

Child Labour.—"Federal legislation should give necessary protection to child workers, with special emphasis on the establishment of (a) a basic minimum age of sixteen for employment; (b) a higher minimum age for employment in hazardous occupations; and (c) a minimum wage provision for minors."

(*See* also PARENT EDUCATION: *United States.*)

PTAH was, in ancient Egyptian religion, the chief deity at Memphis, where Ptah's temple, which included the temple of Apis and others, was one of the main structures.

A human-headed god with a Semitic name, "the Opener," he was represented as a mummy. He was a legendary creator of the universe.

Ptah, who was a moulder or maker of things, was originally a god of artisans, and was hence called by the Greeks Hephaestus (*q.v.*), the name of the lame Greek god of fire who was considered the patron and divine smith of craftsmen.

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

WHITE-TAILED PTARMIGAN, OR MOUNTAIN GROUSE (LAGOPUS LEUCURUS), SHOWING SUMMER PLUMAGE

PTARMIGAN (*Lagopus*). A gallinaceous bird of several species inhabiting arctic and subarctic regions. In its northern range the plumage becomes pure white; in the southern part the summer plumage of reddish brown barred with black is assumed.

The feet are covered with hairlike feathers which aid in walking over snow. From 6 to 12 eggs of various shades of buff marked with brown are laid in a depression in the ground. (K. P.)

PTERIA, the ancient capital of the "White Syrians" of northern Cappadocia, which Croesus of Lydia is stated by Herodotus to have taken, enslaved and ruined, after he had declared war on Persia and crossed the Halys (Kizil Irmak). Thereafter he fought a battle near the city and retreated across the river to his ultimate defeat at Sardis in 546 B.C. Pteria is mentioned by no other ancient authority. The identification of Pteria with the modern Bogazkoy or Boghaz Keui, about 100 mi. E. of Ankara, once taken for granted, is quite uncertain. The extensive ruins near Bogazkoy are much older and belong to the 2nd millennium B.C. when the Hittite power was flourishing in central Asia Minor. Pteria is probably to be sought elsewhere, in a district nearer to the Black sea.

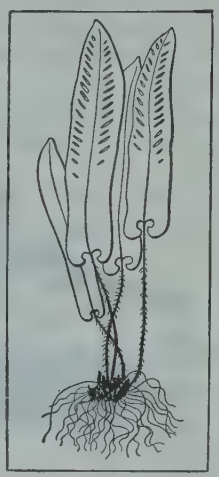
PTERIDOPHYTA, one of the groups comprising the ferns and their allies, of the second great division of plants, the Archegoniatae, the other being the Bryophyta (*q.v.*).

The Pteridophyta thus share with the Bryophyta a middle position between the essentially aquatic Thallophytes and the essentially terrestrial Spermatophytes. Much of their special interest centres round that fact. They include plants well represented at the present day; but many already existed in the early land vegetation of the Devonian period, now known only as fossils; they appeared in greater profusion as fossils of the coal, and many of these early types continued on into the Mesozoic age while their correlatives are included in the flora of the present day. Thus their geological history supports the conclusion that they take a middle position in the evolutionary progression of plant life, in which a transition from life in water to life on land was a striking incident.

Hofmeister first showed that there is essential similarity underlying the life histories of mosses and ferns, and that the same scheme, in modified form, extends to the seed plants also. Since this is so, an account of the Pteridophyta may fitly be introduced by a brief record of the life history of a fern, as an example of the Archegoniatae generally, and of the Pteridophyta in particular. There are two periods in each normally completed life cycle of these plants when the individual is represented by a single cell; and these punctuate the limits between two distinct bodily phases,

or generations as they are called. One of these is the leafy *fern plant* which every one knows; the other is a small green scale-like body, delicate in texture, called the *prothallus*, which escapes the observation of most people, though actually common enough. The former is sexless, but bears *spores* in large numbers; it is the *sporophyte* generation. The latter is the sexual generation, and, since it produces *gametes*, it is called the *gametophyte*.

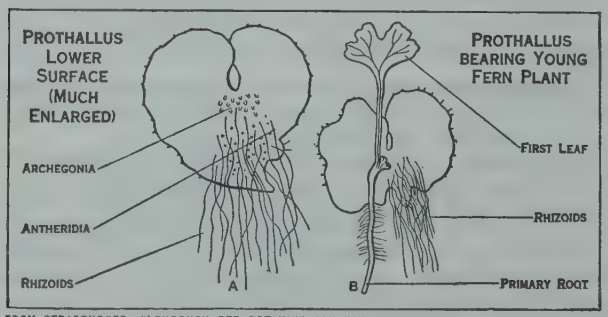
Life-history of a Fern.—The fern plant varies in size from a minute herb to a tree-like body, 60 or even 80ft. in height. It consists of a stem bearing characteristic leaves, usually of large size and delicate outline; the shoot thus constituted is attached by roots to the soil, the whole being traversed by conducting tracts. Since the green leaves serve a nutritional function, the plant is able to subsist as a perennial land-plant (fig. 1). On the leaves the *sori* are borne, of various form and position. In the hart's tongue or the common shield fern they appear as dense groups of brown *sporangia* seated on the lower surface, and covered while young by a membranous indusium. Each sporangium is a stalked capsule containing numerous minute, dry and dusty spores, which are violently ejected when ripe, and each is then liable to be carried away individually by the breeze. The spores are unicellular propagative organs.



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 1.—HART'S TONGUE (PHYLLITIS SCOLOPENDRIUM)

Each spore germinating on moist soil may grow into a prothallus or gametophyte (fig. 2), which never grows large, though being green it is physiologically independent. It bears the *sexual organs* or *gametangia*, usually on its lower surface (fig. 2, A). Near its base are the male gametangia or *antheridia*, which when ripe consist each of a protective wall of cells surrounding numerous spermatocytes. When bathed by external water (rain or dew) the wall ruptures, and each spermatocyte emits a single spiral *spermatozoid*, which moves in the water by lashing cilia (fig. 3). Near the indented apex of the prothallus the female gametangia or *archegonia* are formed (fig. 2). They are flask-shaped organs, also protected by an external wall; each contains a row of three

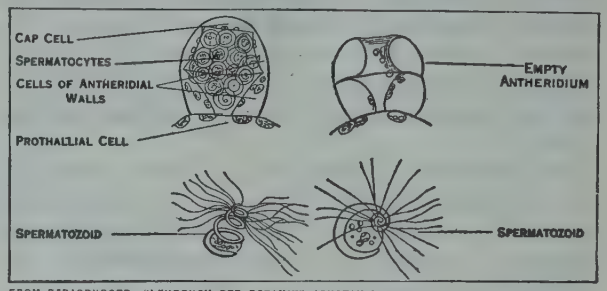


FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 2.—PROTHALLUS OF SHIELD FERN (DRYOPTERIS FILIX-MAS)

cells, of which the lowest and largest is the ovum or egg, sunk in the tissue of the parent (fig. 4). When ripe the archegonium also ruptures on access to external water, the distal cells of the wall parting so that an open channel filled with mucilage leads down to the rounded egg. *Fertilization* (*syngamy*) consists in the fusion of the spermatozoid with the egg to which it is attracted by soluble substance diffusing from it into the water that bathes the open archegonium. The result of that fusion is the *zygote*, which is the starting point for the development of a new fern plant. This new individual appears first as a spherical mass of delicate cells, nursed in the cavity of the archegonium; but it soon bursts out with its first leaf and root, and its apical bud ready to grow into a new fern, while the prothallus rots away (fig. 2, B).

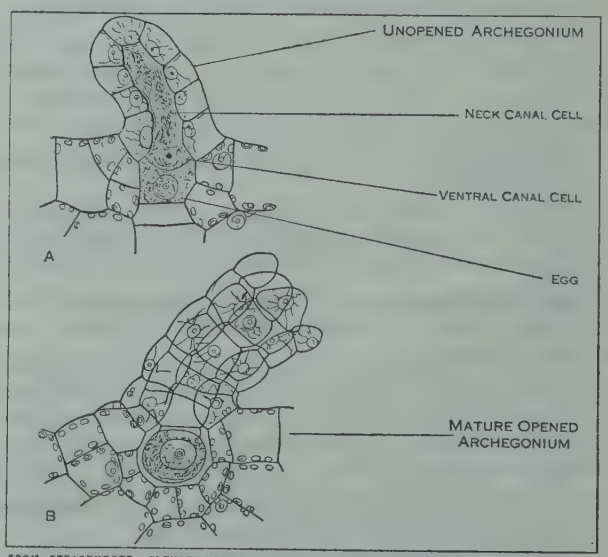
The central feature in syngamy is the *coalescence of the male and female nuclei;* the resulting fusion-nucleus is then *diploid*, with the *2n* number of chromosomes (*see* CYTOLOGY). That character is then maintained throughout the tissues of the sporophyte. On the other hand, when the fern-plant comes to maturity and forms sporangia, the cells that are to form the spores undergo



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 3.—ANTHERIDIUM OF POLYPODY (POLYPODIUM VULGARE)

a nuclear change, called *reduction* or *meiosis*, by which they resume that simpler constitution possessed by the nuclei of the prothallus, and described as *haploid* (*n*). These events normally alternate in regular succession, and they constitute that *nuclear cycle* which underlies all normal life-histories of the Archegoniatae. They stamp structurally the distinction of the two alternating generations. Such alternation, in one form or another, appears in all plants that show sexuality. The Pteridophyta illustrate the cytological cycle with unusual clearness, since the two somatic phases (viz., the haploid prothallus and the diploid fern plant) are so unlike, and so markedly independent the one of the other during their adult existence. It seems probable that in the course of evolution some simple form of alternation present in an algal



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 4.—ARCHEGONIUM OF POLYPODY (POLYPODIUM VULGARE)

ancestry has been regularized and standardized in the Archegoniatae in accordance with a passage from the relative uniformity of aquatic life to the more varied vicissitudes of life on land. In the Bryophyta the gametophyte was more adaptive, and became the dominant generation; on the other hand, in the Pteridophytes, as also in all the higher land-plants, the sporophyte became specialized as the dominant land-living organism. But the Archegoniatae themselves were never wholly emancipated from dependence on external liquid water. They show their amphibious character by their zoidiogamic fertilization; and this confirms their position as primitive land-plants.

For the most part the Pteridophyta are like the Bryophyta in

possessing only one type of spore (*homosporous*); but they produce these in enormous numbers. A common shield fern may ripen over 50,000,000 of them in a season. This is a primitive mode of propagation characteristic of early vegetation.

On the other hand, some few Pteridophyte-types such as *Selaginella* and *Isoetes*, and those curious little fern-derivatives styled collectively the Hydropterideae, possess sexually-differentiated spores, and are described as *heterosporous;* numerous smaller spores (*microspores*) bear each a rudimentary male prothallus, while a few larger spores (*megaspores*), or only a single one, produce each a massive female prothallus. In this they show a state of specialized advance along lines that have led to the final success of the flowering plants. The Pteridophytes as a whole present the paradox of a great division of the vegetable kingdom that has achieved success by force of numbers, rather than by the more refined methods of physiological adjustment and of propagation even in the higher plants. These paragraphs, of necessity rather technical, will suffice to introduce the Pteridophyta, Vascular Cryptogams, or fern-allies as they are sometimes called. They are represented by six natural groups or classes of organisms, of which four include forms both living and fossil, but two are known only as extinct and very early fossils. Such facts at once confirm their position as representing a primitive vegetation. They may be arranged in rough sequence according to their complexity of form and structure; but this must not be understood as conveying any definite view as to affinity.

CLASSIFICATION

I. Psilophytales, comprising only fossil types of simple conformation, from early Devonian rocks.

II. Psilotales, represented by two genera of living plants, *Psilotum* which is intertropical, and *Tmesipteris* which is confined to Australia.

III. Sphenophyllales, containing extinct Palaeozoic fossils of small size, which hardly extended into the Mesozoic period.

IV. Equisetales, including only the single living genus of the horsetails (*Equisetum*), but largely represented also by Palaeozoic fossils often of dendroid form (Calamariaceae).

V. Lycopodiales, or so-called club-mosses, well represented at the present day by the large genera, *Lycopodium* and *Selaginella;* also by *Phylloglossum* and *Isoetes*. But in the Palaeozoic period there existed the giant Lepidodendroid trees, as well as allied plants of humbler dimensions.

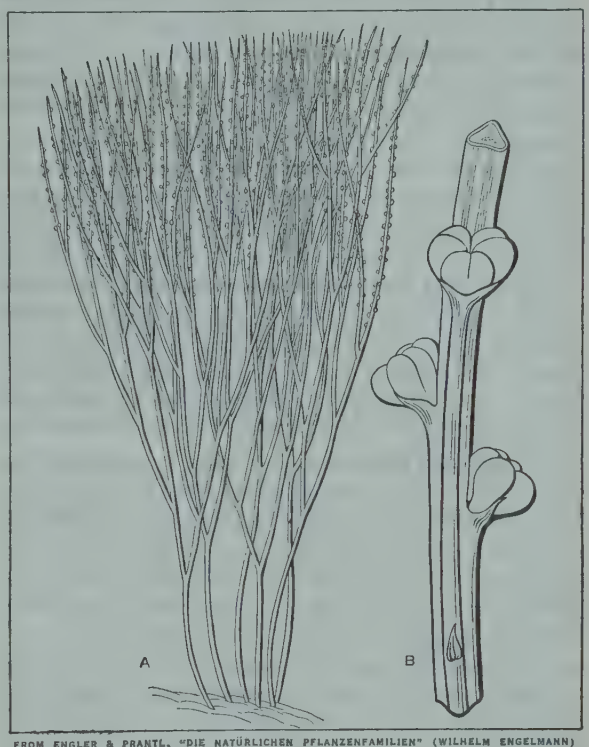
VI. Filicales, or ferns; these comprise not only the living ferns, with about 150 genera and over 6,000 species, but also a rich sequence of fossils, from the Palaeozoic Coenopteridaceae to the most recent strata.

FROM KIDSTON & LANG IN BOWER, "FERNS" (CAMBRIDGE UNIVERSITY PRESS)

FIG. 5.—HORNEA LIGNIERI

A newer scheme of classification treats the higher categories in a somewhat different manner. The phyla Pteridophyta and Spermatophyta (Seed Plants) are united into one group, the Vascular Plants or Tracheophyta. This includes four subdivisions: (1) the Psilopsida, including the Psilophytales and Psilotales, (2) the Lycopsida, including the Lycopodiales, (3) the Sphenopsida, including the Equisetales and Sphenophyllales and (4) the Pteropsida, including the Filiciniae, the Filicales of the above treatment, and also the Gymnospermae and Angiospermae, the two large groups of seed plants.

I. Psilophytales.—This new class of plants was constituted by Kidston and Lang to receive certain fossils of early Devonian time, discovered by Dr. Mackie at Rhynie in Aberdeenshire. Its name is taken from the old genus *Psilophyton* of Dawson, and the class now comprises a number of other genera of like age, more recently discovered, forming together a very distinctive flora. But of these only the sporophyte is known (fig. 5). The vegetative system consists of upward-growing, forked, aerial shoots that spring from a rhizome sometimes creeping, sometimes tuberous and mycorhizic; sometimes the underground branchlets are rootlike, forking in the substratum (*Asteroxylon*). The erect shoots are cylindrical, and were evidently green, covered by an epidermis, with stomata, and they are traversed by conducting strands of simple structure. Various superficial growths, often with the appearance of thorns or prickles, are borne upon the larger branches, as in *Psilophyton* and *Asteroxylon*. The plants



FROM ENGLER & PRANTL, "DIE NATÜRLICHEN PFLANZENFAMILIEN" (WILHELM ENGELMANN)

FIG. 6.—PSILOTUM TRIQUETRUM. (A) HABIT OF PLANT, SHOWING DICHOTOMOUS BRANCHING (B) PART OF A SHOOT

were of low stature, and growing gregariously they must have looked rather like grass. The genera *Hornea, Rhynia* and *Asteroxylon,* described by Kidston and Lang were so well preserved that their structure is as well known as though they were modern plants. The class stands conspicuously apart as leafless and rootless vascular plants.

The most distinctive feature of the class for diagnosis is that the large sporangia, protected by a wall of many layers and containing numerous homosporous spores, are terminal on the vegetative twigs. The early existence thus demonstrated of leafless, and rootless and homosporous vascular plants, with distal sporangia of primitive construction is a fact of the first comparative importance. It is true it does not demonstrate any nearer connection with the Algae, but as regards other relations the new facts are highly suggestive. Long ago it was remarked that the widest gap in the sequence of plants was that between the Bryophytes and Pteridophytes. It is within this gap that the newly discovered fossils take their natural place, acting as synthetic links for the whole sequence of land-living, sporangium-bearing plants.

II. Psilotales.—The Psilotales are represented by two living genera, *Psilotum* and *Tmesipteris,* of which both generations are now known. They form a natural family of the Psilotaceae. By their features they appear remarkably isolated among living plants, and their nearest affinity is to be sought among the Psilophytales and Sphenophyllales, both being classes of plants long extinct. These two genera appear in fact as living fossils.

They live epiphytically, or in soil rich in humus, and are rootless. The green, more or less shrubby shoot is fixed in the substratum by much branched leafless rhizomes, which are infected

by a mycorhizic fungus. The saprophytic nutrition by these is supplemented by photosynthesis in the green leafy shoots. In *Psilotum* the aerial stems bifurcate, bearing small and simple scaly leaves, which however pass upwards into bifid "sporophylls," and between the two teeth is seated a large trilocular synangium, containing numerous homosporous spores (fig. 6). *Tmesipteris* resembles it in general character, but branching is infrequent, the leaves and "sporophylls" are larger, and the synagium has only two large loculi. The anatomy of the green stem of *Psilotum*, with its epidermis and stomata, its photosynthetic cortex and conducting protostele, is on the same general plan as that of *Rhynia* or *Asteroxylon;* the bifurcation and presence of minute leaves, and the rootless mycorhizic base all support the comparison with the Devonian types of Rhynie.

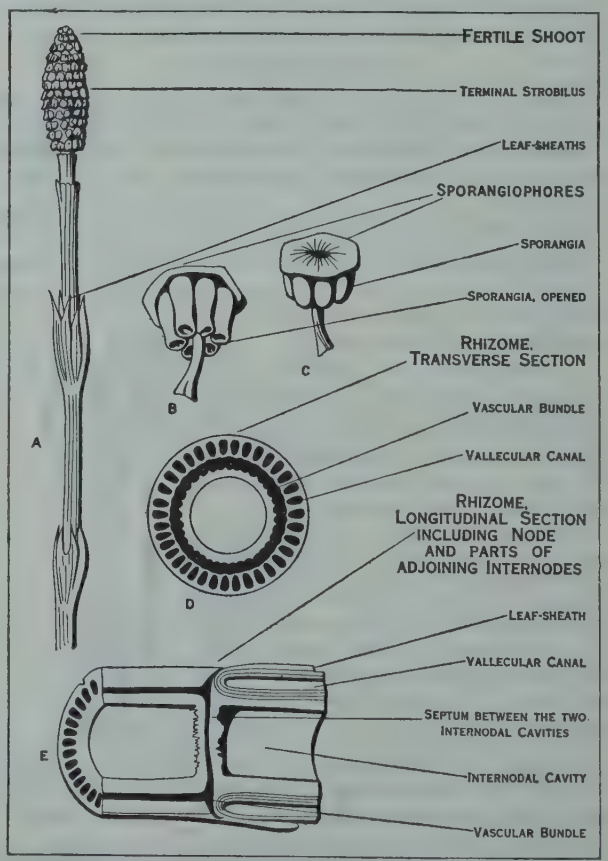
The prothalli of both genera have been discovered since 1914. They are colourless, nourishing themselves saprophytically through fungal agency. In fact these primitive plants conform in their life-cycle to what is seen in many primitive ferns and Lycopods. Moreover, the embryology has been traced in *Tmesipteris;* there is neither suspensor, nor root, nor cotyledon. The embryo with its apex directed, like that of the Bryophytes towards the neck of the archegonium, soon bursts its way out, proceeding to branch distally and form a leafless rhizomic system from which aerial shoots arise later. Such details of the gametophyte link the Psilotales, and indirectly the Psilophytales, with other Pteridophytes as regards alternation on the whole; but the rootless and leafless embryo presents a state that finds its nearest comparison with the Bryophyta.

III. **Sphenophyllales.**—The two genera *Sphenophyllum* and *Cheirostrobus* are the representatives of this class, but in more or less loose association with them are such types as *Pseudobornia* and *Hyenia;* these suggest that the articulate type of land-plants, which they all illustrate, in common with the horsetails, was well represented in the primary rocks. The existence of the Sphenophyllales extended from the Upper Devonian to Triassic time. (For details of Sphenophyllales *see* PALAEOBOTANY.)

IV. **Equisetales.**—Those Pteridophyta which have their appendages disposed in successive whorls, with long internodes intervening between them, have been designated the Articulatae. In the distant past this type was strongly represented by the Sphenophyllales, and by the Calamariaceae and others. But it is familiar to us to-day as it is seen in the horsetails, included in the cosmopolitan genus *Equisetum*, the only species of Equisetaceae, and the only living representatives of the Equisetales. These are semi-aquatic plants; they vary in height from a few inches to 30ft. or more, and are rhizomatous, with erect shoots arising from richly branched, subterranean stems, which are themselves rooted in the soil. The habit of the plants depends upon the method of branching of the shoot rather than upon the foliage, for the leaves are minute (microphyllous), and closely appressed to the stem that bears them. Each whorl of them forms a sheath closely investing the base of the next higher internode, while the teeth projecting upwards from it are all that represent the individual leaves. Their position alternates in successive nodes (fig. 7). The internodes are fluted, the ridges being continuous downwards from the next higher leaves; consequently those of successive internodes alternate. The number of the leaves in a whorl may vary according to the size of the stem, from three to 20 or 30. This is the scheme of the shoot in all species of *Equisetum*, and the shoot is constantly of radial construction. In some species the branching is sparse (*E. limosum*); in others it is profuse (*E. sylvaticum* and *maximum*), and the branches may themselves branch again repeatedly. Their number and the degree of secondary branching defines the habit, and justifies for the more bushy types the familiar name of horsetails. The branches arise in the axils of the leaf-sheaths, but they alternate with the leaves themselves. Many of those initiated remain dormant. A root is found at the base of each bud, but it also is frequently dormant, especially in aerial shoots. The structure of the underground rhizome is on the same plan as that of the aerial branches that it bears. Thus the whole plant consists of a succession of shoots, each with a dominant axis, whorls of subordinate leaves, and accessory roots.

In the transverse section of an aerial internode the sinuous outline shows the projecting ridges and depressed furrows of its fluted form, though this is less evident in the rhizomes (fig. 7, D). The centre of the section is occupied by a large air-cavity, surrounded by the remains of the pith. A circle of isolated vascular strands, corresponding in number to the leaves in the next whorl above, is in most species enclosed by a sinuous endodermis, which thus delimits the stele (*E. arvense*, etc.). Outside this lies the cortex, marked by an equal number of large air-cavities, which alternate with the vascular strands, and correspond to the furrows of the fluting. The vascular strands themselves are opposite the projecting ridges, and are extended upwards into the several leaf-teeth. Between the ridges are regions of green chlorophyll-parenchyma, while the whole is invested by a well-marked epidermis, with curiously elaborate stomata: these are ranged along the furrows, and so are opposite the photosynthetic tissue. The anatomy is clearly that of a semi-aquatic plant with its reduced vascular tissue and large air-spaces.

The sporangia of *Equisetum* are borne upon lateral appendages of the axis, sporangiophores, which are disposed in whorls, and are associated in definite strobili or cones, borne distally (fig. 7, A). Each sporangiophore consists of a stalk that expands into a peltate disc, from the inner surface of which some

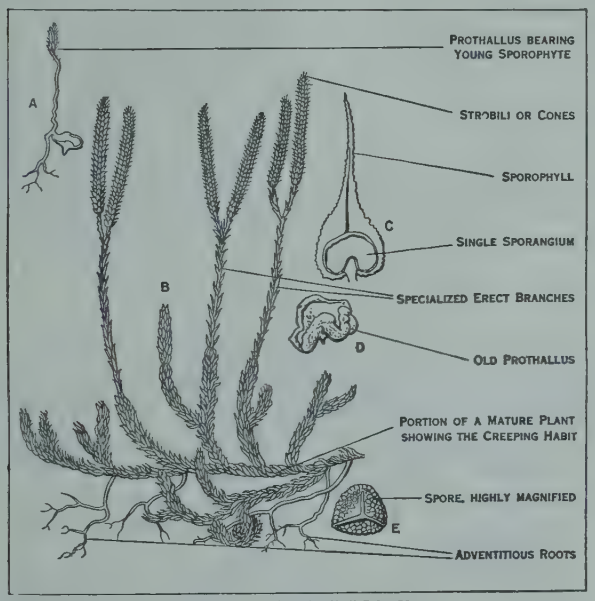


FROM (A, B, C) STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 7.—LARGER HORSETAIL (EQUISETUM TELEMATEIA)

six to nine large sporangia hang parallel with the stalk (fig. 7, B, C). A single vascular strand passing through the stalk supplies a branchlet to each sporangium. These arise as massive growths from the first, and each produces a large output of homosporous spores (eu-sporangiate). The spores themselves are large; in ripening the outermost layer of the wall of each splits along spiral lines, giving rise to four elaters that straighten out when dry, and close round the spore in damp air. They are effective in forcing open the sporangium, which dehisces by a longitudinal

slit: and those of different spores hooking together, the spores are grouped in germination, a matter of importance since the sexes are usually borne on separate prothalli. The spores germinate at once, producing each a green prothallus, which may be filamentous, flattened, or irregularly lobed. The smaller bear sunken antheridia, each with numerous spermatocytes, from which spermatozoids are liberated on access of water. The larger bear archegonia. The conditions of syngamy and formation of the embryo are essen-



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 8.—A CLUB-MOSS (LYCOPODIUM CLAVATUM)

tially as in ferns; but here the embryo has its apex directed to the archegonial neck (exoscopic), and it grows out directly into the apex of the young plant, successive whorls of leaves arising laterally upon it; a root derived from the basal region fixes the young plant in the soil. Notwithstanding the differences of detail, the life-cycle of a horsetail is comparable as a whole with that of a fern.

A greatly added interest in *Equisetum* arises from comparison with allied fossils; for not only were these numerous and of early occurrence, but they attained dendroid proportions, while some were heterosporous. They are grouped as the Calamariaceae, which will be specially treated elsewhere (*see* PALAEOBOTANY).

The Equisetales, thus comprising the Equisetaceae and the Calamariaceae, form a natural and closely related class, of which the nearest affinity was with the Sphenophyllales, but with some degree of relation also with the Psilotales; all of these being sporangiophoric Pteridophytes.

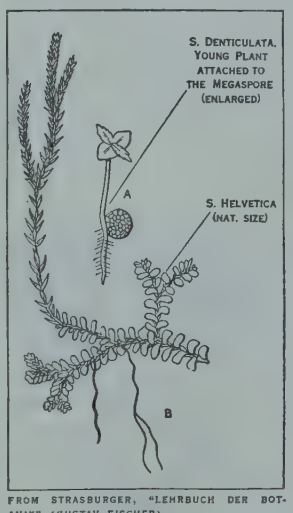
V. **Lycopodiales.**—This class comprises a considerable number of species now living widely distributed upon the earth, and known as *club-mosses;* though they are in fact vascular plants, and quite distinct from the true mosses. They are all relatively small, and indeed insignificant as features in the present flora, compared with the fossil types which, though they may have included a number of relatively small species, comprised also some of the largest plants of the forests of the coal period. It may be that among the lycopods no actual diminution in size took place as time went on, but rather that the types which were always small survived, while the giant members of the group became extinct.

The features which all club mosses have in common are that the leaves are relatively small and simple in form (*microphyllous*), while the sporangia are seated singly, one in the axil of each leaf of the fertile region, or spreading outwards on its base. This marks off the Lycopodiales clearly from the sporangiophoric Pteridophytes on the one hand, and from the Filicales on the other. As in the former, however, the axis is dominant in the adult shoot, and forks equally or unequally. According to the position assumed by the stem the habit of living club mosses is upright or pendent; but frequently, as in the stag's horn moss common on Scottish hills, with its creeping stem rooted in the soil, and bearing upright fruiting branches (fig. 8, B).

The class is divided systematically according to the presence or absence of a *ligule,* which is a small scale-like body borne on the upper surface of each leaf, near its base. Those in which no ligule is present, the ELIGULATAE, include *Lycopodium* and *Phylloglossum,* together with certain early fossils designated *Lycopodites;* those which possess a ligule, the LIGULATAE, include *Selaginella* and *Isoetes,* and with these are associated the fossil Lepidodendraceae and Sigillariaceae. The distinction is accentuated by the fact that the former are all homosporous, the latter heterosporous.

A. Lycopodiales Eligulatae. Lycopodium comprises about 100 species of small plants of varied habit, creeping, shrubby or epiphytic. The construction of the shoot is uniformly microphyllous, the bifurcating stem dominating the conformation of the whole plant. The leaves are simple and small, and in some species uniform throughout the plant. In others the sterile leaves are larger than the membranous sporophylls, the latter being associated in definite strobili, or cones (fig. 8, B). The former probably represent the more primitive type. Each of the isolated sporangia is seated at the base of its sporophyll; it is large, and kidney-shaped, with a short massive stalk, and it dehisces like an oyster-shell, in a plane parallel to that of the leaf. The arrangement of the leaves is sometimes in regular whorls, but frequently it is according to some more or less interrupted spiral scheme. The plant is fixed at its base by roots which spring endogenously from the stem, and show bifurcation.

The stem of *Lycopodium* is seen in transverse section to be surrounded by a bulky and often indurated cortex, and traversed by a stele continued to the apical cone itself, while from each leaf a minute vascular strand passes to its periphery. In the young stem there is a solid woody core, surrounded by phloem and ill-defined sheaths. But in fully-grown stems the core may be invaded by tracts of phloem, moulding it into a cruciform or stellate transverse section, or even separating it into distinct radiating plates, or permeating it to form a sort of woody sponge.



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 9.—A CLUB-MOSS (SELAGINELLA)

The sporangia are massive from the first, and vary slightly in spread along the leaf-surface, a point of interest for comparison with the ligulate types. Each produces after the usual tetrad-division a large number of homosporous spores, which germinate slowly. The prothalli produced from them, and the embryology that follows, vary more than is usual in a single genus. The prothallus sometimes grows at soil-level and is green (*L. cernuum*); but often it is underground and wholly saprophytic (*L. clavatum,* fig. 8, D, A). Whatever its form, the sex-organs are massive and deeply sunk, and both are present on the same prothallus. The antheridia produce numerous biciliate spermatozoids; the archegonia vary in length of neck, and sometimes have numerous canal-cells. But the egg is deeply seated, and produces an embryo with a suspensor. This thrusts the embryo deep into the prothallus, where it often develops juvenile characters of importance for comparison. The most striking of these is the swollen "protocorm," a tuberous growth seen in *Hornea,* and present also in *Phylloglossum.* Bursting out from the prothallus the embryo develops shoot and root, the former in the underground types finding its way upwards to the soil-level (fig. 8, A).

B. Lycopodiales Ligulatae. *Selaginella* comprises about 500 species, widely spread through the tropics, some native on temperate hill stations. The latter, chiefly of exposed habit, have radial symmetry, but most *Selaginellas* are dorsiventral and live under shade. The genus shares the leading features of *Lycopodium,* but it differs in the presence of a ligule and in the fact that all the species are heterosporous.

Various *Selaginellas* are favourite greenhouse plants, and the fanlike spread of the delicate branches with their dimorphic leaves is well known (fig. 9, B); also the strange rhizophores springing from points of branching of the shoot, which turning downward give rise to the true roots, being themselves organs of indeterminate morphological nature. It is unnecessary to describe the vegetative organs or their anatomy in detail; the chief comparative interest lies in the propagative process.

The sporangia are borne on radially constructed distal cones. A single sporangium, similar to that of *Lycopodium,* is borne just above the insertion of each sporophyll, with the ligule protecting it from without. The microsporangia are brownish when ripe and the megasporangia pale in colour, and both may be borne on a single cone. They appear all alike up to the stage when the numerous spore-mother-cells are formed. If all the spore-mother-cells undergo tetrad division, numerous microspores resembling those of *Lycopodium* result. But in a megasporangium only one, or at most a few of them, form tetrads, and the resulting spores are large with a rugged wall; the number matured in a single sporangium may vary from one to four, or some multiple of four. On germination each microspore produces a small number of spermatozoids from a very reduced prothallus; but the large megaspore forms a more bulky prothallus, which, projecting from the disrupted wall, bears archegonia. One of these on fertilization develops an embryo with a suspensor. The essentials of the process are as in *Lycopodium,* though the details are different. As the sporeling develops its leafy shoot grows upward and its root downward; with the megaspore attached laterally the whole has the appearance of a seedling of some flowering plant (fig. 9, A). This is clearly an advance upon *Lycopodium.*

The other genus, *Isoetes,* is peculiar in habit and in habitat, yet shares many of the characteristics of *Selaginella.* It contains about 50 species of tufted herbs, mostly living at the bottom of freshwater lakes, though a few are amphibious or terrestrial. The plant consists of a short, massive, lobed stock, bearing crowded awl-shaped leaves of considerable length. Each bears a ligule on its upper surface, and when fertile, as any one of them may be, a large cakelike sporangium lies between this and the axis. Roots with dichotomous branching arise from furrows between its lobes. The sporangia are heterosporous, and propagation is essentially similar to that in *Selaginella;* but there is no suspensor, and the spermatozoids are multiciliate.

A chief interest in these Ligulate types lies in their comparison with the Lepidodendraceae and Sigillariaceae, for these are also ligulate and heterosporous (*see* PALAEOBOTANY). These fossils attained dendroid dimensions, and, though the primary vascular system was not unlike that of the modern Lycopods, they often differed in having secondary growth with an active cambium. In *Isoetes* there is a sluggish secondary growth in the short stock, which itself shows certain analogies with the Stigmarian trunks of the gigantic fossils. Since any of the leaves of *Isoetes* may be fertile the whole plant appears as a strobilus of the same nature as *Lepidostrobus,* seated upon a Stigmarian base. In fact *Isoetes* is like a telescoped, but still living, fossil.

VI. **Filicales.**—The Filicales may be held as comprising all the living Megaphyllous Pteridophytes, together with such fossils as show essentially similar characters. But the mere fact that their leaves are relatively large in proportion to the stem that bears them is not a sufficient diagnosis. Some Lycopods (*Isoetes, Sigillaria*) share this character, and megaphylly is possible in any of Pteridophytes. But as a matter of fact, excepting *Isoetes,* none such are now living other than the Filicales. The most distinctive feature of ferns, however, is that *on the relatively large leaves many sporangia are borne, either singly or in groups* (*sori*).

Ferns are represented at the present day by about 150 genera and 6,000 species. Some are minute, others attain considerable size as tree ferns; but none can be reckoned among the largest of living plants, nor is there fossil evidence that ferns ever attained extreme dimensions. Their geographical spread is general; a few are arctic, but ferns increase in numbers both of species and of individuals toward the equator. Most are mesothermal hygrophytes (*i.e.,* they flourish under moist conditions with a moderate temperature), and the majority are shade-loving. Hence their headquarters are in the mountains of the tropics, where they form a considerable part of the undergrowth below the forest canopy. But their habitat is variable; some specialized types are actually aquatic, while others are able to withstand conditions of moderate, some even of extreme, drought. Ferns are much richer in genera, species and individuals than any other living Pteridophytes. They present the climax of successful development in homosporous vascular plants. They show also a high degree of variety both in their vegetative and their propagative characters; these provide good diagnostic features for their classification. They have a full and long palaeontological history that stretches back to Palaeozoic times. The geological record can therefore be used as a valid check upon the conclusions drawn from the comparison of living types.

It has been said that the Palaeozoic period was the age of ferns, and it is true that "fernlike" leaves were then common. But it has now been shown that many of these belonged to seed plants ranked as Pteridosperms, a class long since extinct, which also had fernlike leaves (*see* PALAEOBOTANY). It is not improbable that they represent a stock more distinct from ferns than the similarity of their foliage would suggest, for they had advanced early to seed formation. It may be left as an open question whether or not both may have had far back in their evolution some common origin.

The life history already described at the opening of this article holds for ferns generally, so that the grouping and natural classification of the class must depend upon differences of detail other than the life history itself. A general comparison of them led long ago to the recognition of eight main families, which may here be placed in the reverse order to that first given by Mettenius (1856):

I. Ophioglossaceae.	V. Gleicheniaceae.
II. Marattiaceae.	VI. Hymenophyllaceae.
III. Osmundaceae.	VII. Cyatheaceae.
IV. Schizaeaceae.	VIII. Polypodiaceae.

This grouping in linear sequence places the more robust types first and the more delicate last, while the rest take middle positions. The former were styled by Karl von Goebel the *Eusporangiate ferns,* in which the sporangium is from the first a massive body, in the formation of which many cells co-operate; in the latter each sporangium arises from a single cell, and those ferns in which this is so were styled *Leptosporangiate.* Intermediate states exist, and these suggest that the whole series constitutes an evolutionary progression. If this is true the question arises which is the more primitive and which the more advanced state? The importance of this question is enhanced by the fact that the sporangium is a mere index of a general difference of organization of the two contrasted types. In point of fact *the Eusporangiate ferns are relatively robust in their general constitution, while the Leptosporangiate are relatively delicate.* Thus the question is whether there has been in the course of evolution a progression from a robust to a delicate state, or the reverse. Since the Eusporangiate ferns find their correlatives in the fossils of Palaeozoic time and are relatively few today, while the specialized Leptosporangiate ferns are absent from the Palaeozoic rocks and comprise the bulk of living ferns, it is concluded that the general progression has been from a more robust ancestry toward a more delicate and precise constitution.

Having perceived this general scheme of progressive refinement, it cannot be assumed that the 150 genera and 6,000 species have formed a simple sequence. In testing the question of their relationships it will become necessary to revise the methods in use by systematists, whose aims were primarily classification. They worked as a rule upon few criteria of comparison, drawn almost

exclusively from the sporophyte generation. A more exact comparison will be necessary not only as regards external form, but also of internal structure and development, both of the vegetative and the propagative organs, and it must be extended to both generations. The larger the number of the criteria used in comparison the more trustworthy will be the conclusions drawn from them. The criteria currently used in the comparison of ferns are these:

1. The external morphology of the shoot.
2. The initial constitution of the plant-body as indicated by segmentation.
3. The architecture and venation of the leaf.
4. The vascular system of the shoot.
5. The dermal appendages.
6. The position and structure of the sorus.
7. The indusial protections.
8. The characters of the sporangium, and the form and markings of the spores.
9. The spore-output.
10. The morphology of the prothallus.
11. The position and structure of the sexual organs.
12. The embryology of the sporophyte.

By the combined use of these criteria it has been possible to revise the natural groupings of ferns, sometimes amending but more often upholding the decisions of the earlier systematists. The main conclusions may be stated as follows: The *Eusporangiatae* include the living Ophioglossaceae, Marattiaceae and Osmundaceae, together with the fossil Coenopteridaceae (*see* PALAEOBOTANY). All these are Palaeozoic types, though they overlapped into the Mesozoic, and some representatives have even survived to the present day. With them are to be associated also the Schizaeaceae, Gleicheniaceae and Matoniaceae, all of which figured prominently in the Mesozoic, and are well represented among living ferns. In addition to many archaic features of the vegetative system they all possess relatively massive sporangia, which originate simultaneously, being produced either singly or in small numbers in the sori. They are collectively styled *Simplices*. Each sporangium has a relatively large spore-output.

The Ophioglossaceae and Marattiaceae appear to have ended blindly and left no further derivatives. But derivative phyla may be traced by comparison from each of the Schizaeaceae, Osmundaceae, and Gleicheniaceae, while to the Matoniaceae so closely allied to the Dipterids, another phylum may be ascribed. The Schizaeaceae with their solitary marginal sporangia lead to the marginal Dicksoniaceae. The Osmundaceae have many features in common with *Plagiogyria*, while the superficial Gleicheniaceae link on to the Cyatheaceae, these being distinguished by their superficial sori from the marginal Dicksoniaceae. In both of these last-named families the sorus has become "*gradate*," *i.e.*, after the distal sporangia have been formed on the receptacle, a sequence of further sporangia follows *in basipetal sequence*, the effect of which is that the drain of nutrition is spread over a longer period of time. This may well have been a real factor in the success of these families.

A third state of the sorus, which has a like effect to the last, and may either be initiated independently or by transition from the gradate, is the "*mixed*" state, where sporangia of different ages are irregularly *interpolated between those already present*. This is the final condition seen in the evolution of the Leptosporangiate ferns, and is found in all the more advanced types.

From such intermediate stocks as those mentioned some *six derivative phyla of advanced Leptosporangiate ferns* may be distinguished, each centring round some well-known genus. Two of these comparison shows to have been derived from the Dicksoniaceae, viz., the Davallioid ferns centred round *Davallia*, and the Pteroids round *Pteris*. The Gymnogrammoid ferns are naturally grouped round *Gymnogramme*, and may probably be traced from the Osmundaceae, with *Plagiogyria* as a suggestive link. The Cyatheaceae probably gave rise on the other hand to the Blechnoid ferns, with *Blechnum* as a central type; and the Dryopteroids round *Dryopteris*. Lastly, a quite considerable number of genera may be traced as Dipteroid derivatives, from an ancestry suggested by *Matonia* and *Dipteris*. Thus at least six main evolutionary sequences of advanced Leptosporangiate ferns, with more or less pronouncedly "mixed" condition of their sori, may be referred in origin to types already distinct in Palaeozoic, or certainly in Mesozoic time. Each of these will have pursued its own phyletic advance independently of the others. Comparison reveals that most of them, or in some respects all, show parallel features of advance in form, vascular structure, soral characters, and sporangia, and particularly in the reduced spore-output from each sporangium. There is thus wide evidence of independent *homoplastic, and even convergent evolution* in the several phyla. In no respect is this clearer than in the distinctive feature of heterospory: for the Marsileaceae are referable in origin to a Schizaeoid source, while the Salviniaceae, whatever their actual relation, were of distinct origin from the Marsileaceae.

This brief abstract of the present position of the phyletic study of the Filicales can do no more than suggest how the matter stands to-day. Of all the Pteridophyta the ferns yield the most consecutive results. The living representatives of all the rest appear as isolated survivals, illuminated by fossil evidence, often as fragmentary and isolated as theirs. They raise as many evolutionary questions as they solve. It is only in the Filicales that it is possible, by placing together the evidence from palaeontology and that derived from the living flora, to reconstruct a story which, however incomplete, is sufficiently consecutive to serve as a basis for evolutionary opinion. The sum of it is for the ferns, as also for other Pteridophyta, that they have held their own to the present day as a class which has made the best of their amphibious existence by help of profuse production of homosporous spores. But from the point of view of descent, they have led on directly to no further type of land vegetation. The sources of this must be sought elsewhere.

FROM THE CHALLENGER REPORTS (H.M STATIONERY OFFICE)

FIG. 1A.—CEPHALODISCUS DODECALOPHUS. AN ILLUSTRATION OF A FEMALE AS SEEN FROM IN FRONT. (AFTER McINTOSH)

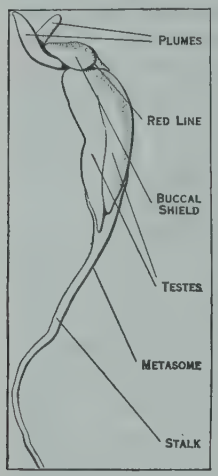
PTEROBRANCHIA. The most strikingly novel discovery of the "Challenger" Expedition was a mysterious animal, dredged from 245 fathoms in the Straits of Magellan. It was described as *Cephalodiscus dodecalophus*, in 1882, and was at first placed in the Polyzoa.

In 1903 it was announced that *Cephalodiscus* had been found by the Swedish Antarctic Expedition, from the original locality southwards to the Antarctic sea; and that it had been discovered off Borneo (near low-water mark), Celebes and Korea.

It was later recorded from new Antarctic or Sub-Antarctic localities, and off New Zealand, South Africa and Ceylon.

The study of the anatomy of this surprising animal revealed the unexpected fact that its affinities are with *Balanoglossus* (*q.v.*), and so the Pterobranchia are included as a class of the Hemichordata (*q.v.*).

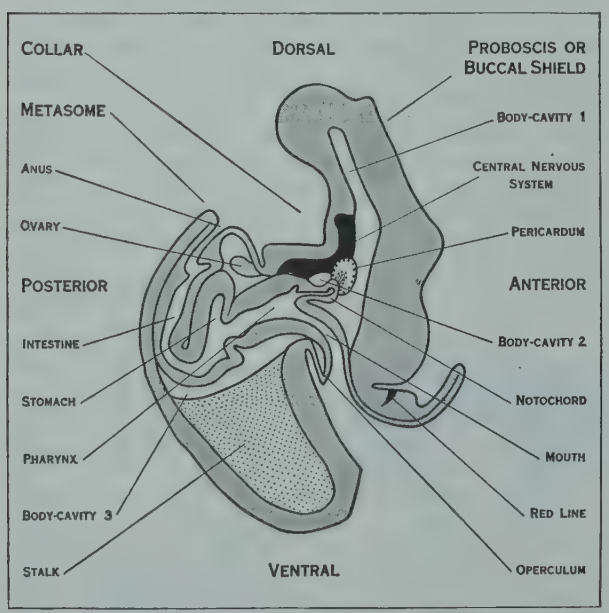
A colony of *Cephalodiscus* inhabits an orange, gelatinous dwelling (*coenoecium*), from a foot to half an inch long. The branches, from two inches to one tenth of an inch across, are composed of numerous laminae, including Foraminifera or other bodies, sometimes so numerous as to mask the gelatinous walls. The animals occur in large numbers, and are from 7 to 1mm. in length, without the stalk, which is very extensible. They can wander on the surface of their dwelling, the lower end of the stalk remaining attached to the wall of the tube, to facilitate retraction.



FROM G. F. HARMER, "MONOGRAPH ON THE SIBOGA EXPEDITION" (MAX WEBER)

FIG. 1B.—A MALE (SIDE VIEW)

The body consists of the three regions characteristic of *Balanoglossus:*—(1) the "proboscis" or "buccal shield" (fig. 2), used as a crawling organ. A crescentic red line, near its lower edge, is distinctive of the genus; (2) the "collar," its front edge produced above into 3–9 pairs of plumes, each with two series of tentacles, and at the sides and below into a large "operculum"; (3) the third segment or "metasome," with the stalk. Each segment has its own body-cavity, unpaired in the proboscis, paired in the other two segments (figs. 2, 3). The first body-cavity opens externally by two "proboscis-pores," on the buccal shield, near its junction with the collar. The second cavities extend into the operculum and the plumes, each opening by a "collar-canal," immediately behind which is a "gill-slit," leading from the pharynx to the exterior (fig. 3). From the upper wall of the pharynx a "notochord" projects into the proboscis-cavity, where there is a "pericardium," corresponding with that of *Balanoglossus*. The central nervous system is in the dorsal region of the collar and of part of the proboscis.



FROM S. F. HARMER, "MONOGRAPH ON THE SIBOGA EXPEDITION" (MAX WEBER)

FIG. 2.—CEPHALODISCUS DODECALOPHUS, MEDIAN SECTION OF AN ADVANCED FEMALE BUD

The third body-cavities contain the alimentary canal and reproductive organs. The anus is on the upper side, the mouth being below, between the proboscis and the operculum. The young alimentary canal (fig. 2) is shortly U-shaped, but in the adult the U is much longer, passing ventrally down the body, the long axis of which is dorso-ventral. The two ovaries or testes open dorsally, in front of the anus, and the oviducts (at first mistaken for eyes) are highly pigmented. The eggs have much yolk, and development commences in the tubes. In certain species the colonies are either male or female, while in others both sexes occur, and an animal may have an ovary on one side and a testis on the other. The males resemble the females except in *C. sibogae* (fig. 1, B), in which they occur with neuter individuals without functional reproductive organs. These males have a single pair of plumes, with no tentacles, the alimentary canal is vestigial and the operculum has been lost. The three segments, their body-cavities, the collar-canals and the central nervous system are normal, but the third segment is mainly occupied by the two testes. The males are probably nourished by vascular connection with the neuters; and blood-vessels have been observed in this and other species. The buds, often in considerable number, remain connected by their stalks with the parent stalk until a late stage, but ultimately become free.

The species of *Cephalodiscus* are most easily recognized by the form of their coenoecium. The number of plumes is not always quite constant, but is a useful character. About 13 species are known, referable to three sub-genera:—*Demiothecia,* with a single cavity extending throughout the colony; and *Idiothecia* and *Orthoecus,* in which each animal, with its system of buds, occupies a separate tube, nearly always isolated from its neighbours. The coenoecium is branched in *Idiothecia,* discoidal or plano-convex in *Orthoecus. Rhabdopleura,* the only other Pterobranch, resembles *Cephalodiscus* in form and structure, but is almost microscopic. It was first described from Norwegian and British seas (in rather deep water), but it occurs from Greenland to the Antarctic sea, including the Azores, the Malay archipelago, Ceylon, New Zealand, Australia and Tristan da Cunha. Several species have been described.

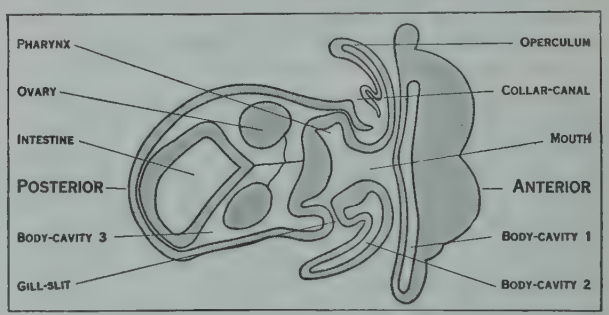


FIG. 3.—CEPHALODISCUS DODECALOPHUS, LONGITUDINAL (FRONTAL) SECTION OF THE FEMALE, SHOWING THE LEFT COLLAR-CANAL AND THE RIGHT GILL-SLIT (AFTER HARMER)

Rhabdopleura has no doubt been simplified, in correlation with its reduction in size. There is only one pair of plumes and gill-slits are not present. In most other respects it agrees with *Cephalodiscus,* to which it is clearly allied. The elongated, cylindrical tubes are about 2–3 mm. long and a quarter of a millimetre in diameter. Each arises vertically from a tube closely attached to a solid object; and all the tubes are composed of laminae, which form distinct rings in the erect parts. The budded individuals do not become free, their stalks remaining connected by a cord. Its jet-black colour, in the adherent part, and the ringed tubes are features easily recognized.

PTEROCLIDAE: *see* SAND-GROUSE.

PTERODACTYL, a term familiarly used for any member of the order Pterosauria, or winged reptiles. The pterodactyls are extinct flying reptiles found in rocks of all ages from the Lower Lias or perhaps the Rhaetic to the Upper Cretaceous. They fall into two great groups distinguished from one another by the

presence of a long tail with a horizontal fin at its tip, in the one, and the lack of a tail in the other.

The best-known form is *Rhamphorhynchus* from the Solenhofen slate of Bavaria and probably the Kimmeridge clay of England. *Rhamphorhynchus* has a head about 3½ in. long, with a mouth opening very widely and armed with long, slender, sharp-pointed teeth. The eye, which is placed above the articulation of the lower jaw, is very large, and like that of many birds has a series of bony plates lying in its wall. The paired nostrils lie far back in front of the eyes. The neck, which is some 2 in. long, was flexible, and the head was carried at right angles to the neck. The body is small, about 4 in. in length by 1¼ in. in diameter. The tail is enormously long (15 in.) and although built of many joints, is stiffened by ossified tendons so that it must have moved as a whole. The wings are stretched membranes made by folds of skin held out by

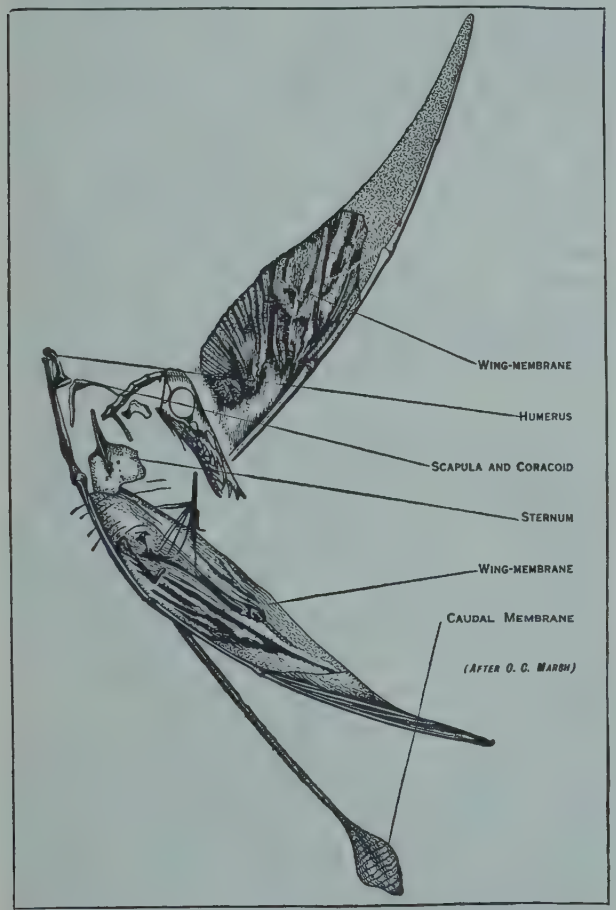

FIG. 1.—RHAMPHORHYNCHUS PHYLLURUS FROM THE SOLENHOFEN LITHOGRAPHIC STONE, WITH THE GREATER PART OF THE WING MEMBRANE PRESERVED

the greatly elongated forelimb, and especially by the enormously extended fourth finger; the width across the wings when fully spread is some 25 inches. The bony finger lies practically at the forward edge of the wing, the membrane which forms the rest of the structure being only some 2 in. from front to back, and passing backwards along the side of the body to the hind leg. The extremity of the tail bears a horizontal flap of membrane. The three first fingers of the hand are free and provided with large claws; they stand out in front of the wings and must have been used for holding food or for help in landing. The knees included in the wing membrane stand straight out from the side of the body, the lower leg is long and there are five slender toes, the first being always curiously bent inwards and downwards. The other four toes seem to have been connected by a web.

Rhamphorhynchus was covered with a smooth skin usually without scales, but the top of the head bore a tuft of hairlike protuberances. The animal appears to have lived like a seagull on fish, and it is exceedingly difficult to understand how it could ever have risen from land or water after alighting.

FIG. 2.—RECONSTRUCTION OF THE SKELETON AND WING MEMBRANE OF A PTERODACTYL, RHAMPHORHYNCHUS SEEN FROM BELOW

The group of tailless pterodactyls was represented in Jurassic times by *Pterodactylus,* a small type in which some species were no larger than a sparrow. In the Cretaceous the long-tailed forms were extinct, but descendants of *Pterodactylus* had persisted and grown greatly in size. They are best represented by *Pteranodon* from the Kansas chalk. This creature had a wingspread of 18 ft. and its head (measured from the tip of the snout to the summit of a great crest which rises from the occiput) is nearly 4 ft. in length. It was perhaps the largest flying animal of which we have any knowledge. Despite its great size it was extremely light, the wing bones consisting of a bony layer no thicker than a visiting card, surrounding an air space which might be more than an inch in diameter; even the bone of an albatross is a crude and heavy structure in comparison. The remains of these giant animals are found in the Kansas and English chalk commonly enough to show that they flew at a distance of some hundreds of miles from land. The brain of these large pterodactyls is extraordinarily like that of a bird, and its characters are such as to suggest that they practically lacked a sense of smell and depended on sight for the capture of their food. *See* REPTILES. (D. M. S. W.; X.)

PTEROMA, in architecture, the colonnade at the side of a classic temple.

PTERON, in architecture, a term used by Pliny the Elder for the peristyle or colonnade of the tomb of Mausolos; loosely and rarely used for any surrounding colonnade or peristyle.

PTOLEMAEUS, of Alexandria, surnamed Chennus, Greek grammarian during the reigns of Trajan and Hadrian. According to Suïdas, he was the author of an historical drama named *Sphinx,* of an epic, *Anthomeros,* in 24 books (both lost) and a *Strange History.* The last is probably identical with the work of which an abridgment has been preserved in Photius (*cod.* 190).

See editions of Photius's abridgment by J. Roulez (1834); and in A. Westermann, *Mythographi graeci* (1843); R. Hercher, *Über die Glaubwürdigkeit der neuen Geschichte des Ptolemäus Chennus* (Leipzig, 1856); J. E. Sandys, *Hist. of Classical Scholarship,* 2nd ed. (1906).

PTOLEMAIS, an ancient city on the coast of Cyrenaica, 70 mi. N.E. of Bengasi, and 28 mi. N.E. of Teuchira (Tocra). Its modern name is Tolmeita or Tolmetta. Of the city walls nothing is preserved, excepting a massive gate on the west, with two towers, at the end of the road from Barce (mod. El Merg). At the further extremity of the town is a fine Roman bridge. Little of the town remains but some very large cisterns.

See *Ministero delle Colonie, Notiziario Archeologico,* i, 114–154 (1915).

PTOLEMIES, a dynasty of Macedonian kings who ruled in Egypt from 323 to 30 B.C.

PTOLEMY I (Πτολεμαῖος), the founder, son of Lagus, a Macedonian nobleman of Eordaea, was one of Alexander the Great's most trusted generals, and among the seven "bodyguards" at-

tached to his person. He plays a principal part in the later campaigns of Alexander in Afghanistan and India. At the Susa marriage festival in 324 Alexander caused him to marry the Persian princess Artacama; but there is no further mention of this Asiatic bride in the history of Ptolemy. When Alexander died in 323 the resettlement of the empire at Babylon is said to have been made at Ptolemy's instigation. At any rate he was now appointed satrap of Egypt under the nominal kings Philip Arrhidaeus and the young Alexander. He at once took a high hand in the province by killing Cleomenes, the financial controller appointed by Alexander the Great; he also subjugated Cyrenaïca. He contrived to get possession of Alexander's body which was to be interred with great pomp by the imperial government and placed it temporarily in Memphis. This act led to an open rupture between Ptolemy and the imperial regent Perdiccas. But Perdiccas perished in the attempt to invade Egypt (321). In the long wars between the different Macedonian chiefs which followed, Ptolemy's first object was to hold his position in Egypt securely, and secondly to possess the Cyrenaïca, Cyprus and Palestine (Coele-Syria). His first occupation of Palestine was in 318, and he established at the same time a protectorate over the petty kings of Cyprus. When Antigonus, master of Asia in 315, showed dangerous ambitions, Ptolemy joined the coalition against him, and, on the outbreak of war, evacuated Palestine. In Cyprus he fought the partisans of Antigonus and reconquered the island (313). A revolt of Cyrene was crushed in the same year. In 312 Ptolemy, with Seleucus, the fugitive satrap of Babylonia, invaded Palestine and beat Demetrius, the son of Antigonus, in the great battle of Gaza. Again he occupied Palestine, and again a few months later, after Demetrius had won a battle over his general and Antigonus entered Syria in force, he evacuated it.

In 311 a peace was concluded between the combatants, soon after which the surviving king Alexander was murdered in Macedonia, leaving the satrap of Egypt absolutely his own master. The peace did not last long, and in 309 Ptolemy commanded a fleet in person which detached the coast towns of Lycia and Caria from Antigonus and crossed to Greece, where Ptolemy took possession of Corinth, Sicyon and Megara (308). In 306 a great fleet under Demetrius attacked Cyprus, and Ptolemy's brother, Menelaus, was defeated and captured in the decisive battle of Salamis. The complete loss of Cyprus followed. Antigonus and Demetrius now assumed the title of kings; Ptolemy, as well as Cassander, Lysimachus and Seleucus, answered this challenge by doing the same. In the winter (306–5) Antigonus tried to follow up the victory of Cyprus by invading Egypt, but here Ptolemy was strong, and held the frontier successfully against him. Ptolemy led no further expedition against Antigonus overseas. To the Rhodians, besieged by Demetrius (305–4), he sent such help as won him divine honours in Rhodes and the surname of *Sotēr* ("saviour"). When the coalition was renewed against Antigonus in 302, Ptolemy joined it, and invaded Palestine a third time, whilst Antigonus was engaged with Lysimachus in Asia Minor. On a report that Antigonus had won a decisive victory, for a third time he evacuated the country. But when news came that Antigonus had been defeated and slain at Ipsus (301) by Lysimachus and Seleucus, Ptolemy occupied Palestine for the fourth time. The other members of the coalition had assigned Palestine to Seleucus after what they regarded as Ptolemy's desertion, and for the next hundred years the question of its ownership becomes the standing ground of enmity between the Seleucid and Ptolemaïc dynasties. Henceforth, Ptolemy seems to have mingled as little as possible in the broils of Asia Minor and Greece; his possessions in Greece he did not retain, but Cyprus he reconquered in 295–4. Cyrene, after a series of rebellions, was finally subjugated about 300 and placed under his stepson Magas (Beloch, *Griech. Gesch.* III. [ii.], p. 134 *seq.*).

In 285 he abdicated in favour of one of his younger sons by Berenice (*q.v.*), who bore his father's name of Ptolemy; his eldest (legitimate) son, Ptolemy Ceraunus, whose mother, Eurydice, the daughter of Antipater, had been repudiated, fled to the court of Lysimachus. Ptolemy I. Soter died in 283 at the age of 84. Shrewd and cautious, he had a compact and well-ordered realm to show at the end of fifty years of wars. His name for *bonhomie* and liberality attached the floating soldier-class of Macedonians and Greeks to his service. Nor did he neglect conciliation of the natives. He was a ready patron of letters, and the great library, which was Alexandria's glory, owed to him its inception. He wrote himself a history of Alexander's campaigns, distinguished by its straightforward honesty and sobriety.

PTOLEMY II. PHILADELPHUS (309–246) was of a delicate constitution, no Macedonian warrior-chief of the old style. His brother Ptolemy Ceraunus found compensation by becoming king in Macedonia in 281, and perished in the Gallic invasion of 280–79. (*See* BRENNUS.) Ptolemy II. maintained a splendid court in Alexandria. Not that Egypt held aloof from wars. Magas of Cyrene opened war on his half-brother (274), and Antiochus I., the son of Seleucus, desiring Palestine, attacked soon after. Two or three years of war left Egypt the dominant naval power of the eastern Mediterranean; the Ptolemaïc sphere of power extended over the Cyclades to Samothrace, and the harbours and coast towns of Cilicia Trachea ("Rough Cilicia"), Pamphylia, Lycia and Caria were largely in Ptolemy's hands (Theoc. *Idyll.* xvii. 86 *seq.*). The victory won by Antigonus, king of Macedonia, over his fleet at Cos (between 258–56; *see* Beloch, III. [ii.], p. 428 *seq.*) did not long interrupt his command of the Aegean. In a second war with the Seleucid kingdom, under Antiochus II. (after 260), Ptolemy sustained losses on the seaboard of Asia Minor and agreed to a peace by which Antiochus married his daughter Berenice (250?). Ptolemy's first wife, Arsinoë (I.), daughter of Lysimachus, was the mother of his legitimate children. After her repudiation he married, probably for political reasons, his full-sister Arsinoë (II.), the widow of Lysimachus, by an Egyptian custom abhorrent to Greek morality. The material and literary splendour of the Alexandrian court was at its height under Ptolemy II. Pomps and gay religions flourished. Ptolemy deified his parents as the *θεοὶ ἀδελφοί* and his sister-wife, after her death (270), as *Philadelphus*. This surname was used in later generations to distinguish Ptolemy II. himself, but properly it belongs to Arsinoë only, not to the king. Callimachus, made keeper of the library, Theocritus, and a host of lesser poets, glorified the Ptolemaïc family. Ptolemy himself was eager to increase the library and to patronize scientific research. He had the strange beasts of far-off lands sent to Alexandria. But, an enthusiast for Hellenic culture, he seems to have shown but little interest in the native religion. The tradition which connects the Septuagint translation of the Old Testament into Greek with his name is not historical. Ptolemy had many brilliant mistresses, and his court, magnificent and dissolute, intellectual and artificial, has been justly compared with the Versailles of Louis XIV.

PTOLEMY III. EUERGETES I. (reigned 246–221), son of Ptolemy II. and Arsinoë I. At the beginning of his reign he reunited the Cyrenaïca to Egypt by marrying Berenice the daughter and successor of Magas (who had died about 250). At the same time he was obliged to open war on the Seleucid kingdom, where Antiochus II. was dead and his sister Berenice had been murdered, together with her infant son, by Antiochus's former wife, Laodice, who claimed the kingdom for her son Seleucus II. Ptolemy marched triumphantly into the heart of the Seleucid realm, as far at any rate as Babylonia, and received the formal submission of the provinces of Iran, while his fleets in the Aegean recovered what his father had lost upon the seaboard, and made fresh conquests as far as Thrace. This moment marks the zenith of the Ptolemaïc power. After Ptolemy returned home, indeed, Seleucus regained northern Syria and the eastern provinces, but the naval predominance of Egypt in the Aegean remained, although there are traces of its being replaced locally, towards the end of Euergetes' reign, by that of Macedonia—in Amorgos, Naxos, Syros, Nisyros, Cos and parts of Crete. (*See* Beloch, III. [ii.], p. 463.) After his final peace with Seleucus, Ptolemy no longer engaged actively in war.

PTOLEMY IV. PHILOPATOR (reigned 221–204), son of the preceding, was a wretched debauchee under whom the decline of the Ptolemaïc kingdom began. His reign was inaugurated by the murder of his mother, and he was always under the dominion of

favourites, male and female, who indulged his vices and conducted the government as they pleased. Self-interest led his ministers to make serious preparations to meet the attacks of Antiochus III. (the Great) on Palestine, and the great Egyptian victory of Raphia (217), at which Ptolemy himself was present, secured the province till the next reign. The arming of Egyptians in this campaign had a disturbing effect upon the native population of Egypt, so that rebellions were continuous for the next thirty years. Philopator was devoted to orgiastic forms of religion and literary dilettantism. He built a temple to Homer and composed a tragedy, to which his vile favourite Agathocles added a commentary. He married (about 215) his sister Arsinoë (III.), but continued to be ruled by his mistress Agathoclea, sister of Agathocles.

Ptolemy V. Epiphanes (reigned 204–181), son of Philopator and Arsinoë, was not more than five years old when he came to the throne, and under a series of regents the kingdom was paralysed. Antiochus III. and Philip V. of Macedonia made a compact to divide the Ptolemaïc possessions overseas. Philip seized several islands and places in Caria and Thrace, whilst the battle of Panium (198) definitely transferred Palestine from the Ptolemies to the Seleucids. Antiochus after this concluded peace, giving his own daughter Cleopatra to Epiphanes to wife (193–192). Nevertheless, when war broke out between Antiochus and Rome Egypt ranged itself with the latter power. Epiphanes in manhood was chiefly remarkable as a passionate sportsman; he excelled in athletic exercises and the chase.

Ptolemy VI. Philometor (181–145), the elder of his two sons, succeeded as an infant under the regency of his mother Cleopatra. Her death was followed by a rupture between the Ptolemaïc and Seleucid courts, on the old question of Palestine. Antiochus IV. Epiphanes invaded Egypt (170) and captured Philometor.

The Alexandrians then put his younger brother Ptolemy VII. Euergetes II. (afterwards nicknamed *Physkon*, on account of his bloated appearance) upon the throne. Antiochus professed to support Philometor, but, when he withdrew, the brothers agreed to be joint-kings with their sister Cleopatra as queen and wife of Philometor. Antiochus again invaded Egypt (168), but was compelled by the Roman intervention to retire. The double kingship led to quarrels between the two brothers in which fresh appeals were continually made to Rome. In 163 the Cyrenaïca was assigned under Roman arbitration to Euergetes as a separate kingdom. As he coveted Cyprus as well, the feud still went on, Rome continuing to interfere diplomatically but not effectively. In 154 Euergetes invaded Cyprus but was defeated and captured by Philometor. He found his brother, however, willing to pardon and was allowed to return as king to Cyrene. In 152 Philometor joined the coalition against the Seleucid king Demetrius I. and was the main agent in his destruction. The protégé of the coalition, Alexander Balas, married Philometor's daughter Cleopatra (Thea), and reigned in Syria in practical subservience to him. But in 147 Philometor broke with him and transferred his support, together with the person of Cleopatra, to Demetrius II., the young son of Demetrius I. He himself at Antioch was entreated by the people to assume the Seleucid diadem, but he declined and installed Demetrius as king. In 145 in the battle on the Oenoparas near Antioch, in which Alexander Balas was finally defeated, Philometor received a mortal wound. Philometor was perhaps the best of the Ptolemies. Kindly and reasonable, his good nature seems sometimes to have verged on indolence, but he at any rate took personal part, and that bravely and successfully, in war. Philometor's infant son, Ptolemy Philopator Neos (?)[1], was proclaimed king in Alexandria under the regency of his mother Cleopatra. Euergetes however, swooping from Cyrene, seized the throne and married Cleopatra, making away with his nephew. He has left an odious picture of himself in the historians—a man untouched by benefits or natural affection, delighting in deeds of blood, his body as loathsome in its blown corpulence as his soul. Something must be allowed for the rhetorical habit of our authorities, but that Euergetes was ready enough to shed blood when policy required seems true. He soon found a more agreeable wife than Cleopatra in her daughter Cleopatra, and thenceforth antagonism between the two queens, the "sister" and the "wife," was chronic. In 130–1 Cleopatra succeeded in driving Euergetes for a time to Cyprus, when he revenged himself by murdering the son whom she had borne him (surnamed *Memphites*). Massacres inflicted upon the Alexandrians and the expulsion of the representatives of Hellenic culture are laid to his charge. On the other hand, the monument and papyri show him a liberal patron of the native religion and a considerable administrator. In fact, while hated by the Greeks, he seems to have had the steady support of the native population. But there are also records which show him, not as an enemy, but a friend, like his ancestors, to Greek culture. He himself published the fruit of his studies and travels in a voluminous collection of notebooks, in which he showed a lively eye for the oddities of his fellow kings. The old Ptolemaïc realm was never again a unity after the death of Euergetes II. By his will he left the Cyrenaïca as a separate kingdom to his illegitimate son Ptolemy Apion (116–96), whilst Egypt and Cyprus were bequeathed to Cleopatra (Kokke) and whichever of his two sons by her, Ptolemy VIII. Soter II. (nicknamed *Lathyros*) and Ptolemy IX. Alexander I., she might choose as her associate. The result was, of course, a long period of domestic strife. From 116 to 108 Soter reigned with his mother, and at enmity with her, in Egypt, whilst her favourite son, Alexander, ruled Cyprus. Cleopatra compelled Soter to divorce his sister-wife Cleopatra and marry another sister, Selene. Cleopatra plunged into the broils of the Seleucid house in Syria and perished. In 108 Cleopatra Kokke called Alexander to Egypt, and Soter flying to Cyprus took his brother's place and held the island against his mother's forces. The attempts which Soter and Cleopatra respectively made in 104–3 to obtain a predominance in Palestine came to nothing. Alexander now shook off his mother's yoke and married Soter's daughter Berenice. Cleopatra Kokke died in 101 and from then till 89 Alexander reigned alone in Egypt. In 89 he was expelled by a popular uprising and perished the following year in a sea-fight with the Alexandrian ships off Cyprus. Soter was recalled (88) and reigned over Egypt and Cyprus, now reunited, in association with his daughter Berenice. This, his second, reign in Egypt (88–80), was marked by a native rebellion which issued in the destruction of Thebes.

Ptolemy X. Alexander II.—On his death Berenice assumed the government, but the son of Alexander I., Ptolemy X., entering Alexandria under Roman patronage, married, and within 20 days assassinated, his elderly cousin and stepmother. He was at once killed by the enraged people and with him the Ptolemaïc family in the legitimate male line became extinct. Ptolemy Apion meanwhile, dying in 96, had bequeathed the Cyrenaïca to Rome.

The Alexandrian people now chose an illegitimate son of Soter II. to be their king, Ptolemy XI. Philopator Philadelphus Neos Dionysus (80–51), nicknamed *Auletes*, the flute-player, setting his brother as king in Cyprus. The rights of these kings were doubtful, not only because of their illegitimate birth, but because it was claimed in Rome that Alexander II. had bequeathed his kingdom to the Roman people. Two Seleucid princes, children of Soter's sister Selene, appeared in Rome in 73 to urge their claim to the Ptolemaïc throne. Ptolemy Auletes was thus obliged to spend his reign in buying the support of the men in power in Rome. Cyprus was annexed by Rome in 58, its king committing suicide. From 58 to 55 Auletes was in exile, driven out by popular hatred, and worked by bribery and murder in Rome to get himself restored to Roman power. His daughter Berenice meanwhile reigned in Alexandria, a husband being found for her in the Pontic prince Archelaus. In 55 Auletes was restored by the proconsul of Syria, Aulus Gabinius. He killed Berenice and, dying in 51, bequeathed the kingdom to his eldest son, aged ten years, who was to take as wife his sister Cleopatra, aged seventeen.

In the reign of Ptolemy XII. Philopator (51–47) and Cleopatra Philopator, Egyptian history coalesces with the general

[1] Or according to another view, Eupator. On the obscure questions raised by these two surnames, *see* L. Pareti, *Ricerche sui Tolemei Eupatore e Neo Filopatore* (Turin, 1908).

history of the Roman world, owing to the murder of Pompey off Pelusium in 48 and the Alexandrine War of Julius Caesar (48–47).

In that war the young king perished and a still younger brother, PTOLEMY XIII. Philopator, was associated with Cleopatra till 44, when he died, probably by Cleopatra's contriving. From then till her death in 30, her son, born in 47, and asserted by Cleopatra to be the child of Julius Caesar, was associated officially with her as PTOLEMY XIV. Philopator Philometor Caesar; he was known popularly as Caesarion. (For the incidents of Cleopatra's reign *see* CLEOPATRA, ARSINOË.) After her death in 30 and Caesarion's murder Egypt was made a Roman province. Cleopatra's daughter by Antony (Cleopatra Selene) was married in 25 to Juba II. of Mauretania. Their son Ptolemy, who succeeded his father (A.D. 23–40), left no issue[1].

See Mahaffy, *The Empire of the Ptolemies* (1895) and *Egypt under the Ptolemaïc Dynasty* (1899); Strack, *Die Dynastie der Ptolemäer* (1897); Bouché-Leclercq, *Histoire des Lagides* (1904, 1907); Meyer, *Das Heerwesen der Ptolemäer und Römer* (Leipzig, 1900).

(E. R. B.)

PTOLEMY (CLAUDIUS PTOLEMAEUS), of Alexandria, the celebrated mathematician, astronomer and geographer, was, according to the Byzantine Theodorus Meliteniota (*c.* 1361), born at Ptolemais Hermii, a Grecian city of the Thebaid. All that is known for certain about him is that he observed at Alexandria during the reigns of Hadrian and Antoninus Pius, between the years A.D. 127 and 141 or 151. Olympiodorus, a philosopher of the Neoplatonic school, who lived in the reign of the emperor Justinian, relates in his scholia on the *Phaedo* of Plato that Ptolemy devoted his life to astronomy and lived for 40 years in the so-called Περὶ τοῦ Κανώβου, probably elevated terraces of the temple of Serapis at Canopus, near Alexandria, where they raised pillars with the results of his astronomical discoveries engraved upon them. Arabian traditions say that Ptolemy lived to the age of 78 years, and give some details about his personal appearance, to which too much weight must not be attached.

His Work as a Mathematician.—Ptolemy's work as a geographer is discussed below, and an account of the discoveries in astronomy of Hipparchus and Ptolemy is given in the article ASTRONOMY: *History*. Their contributions to pure mathematics, however, require to be noticed here. Of these the chief is the foundation of trigonometry, plane and spherical, including the formation of a table of chords, which served the same purpose as our table of sines. This branch of mathematics was created by Hipparchus for the use of astronomers, and its exposition was given by Ptolemy in a form so perfect that for 1,400 years it was not surpassed. The doctrine as to the motion of the heavenly bodies known as the Ptolemaic system, was paramount for about the same period of time. The astronomical and trigonometrical systems are contained in the great work of Ptolemy, Ἡ μαθηματικὴ σύνταξις or *The Mathematical Collection*. Later it came to be known as the μεγάλη σύνταξις or alternatively as Ὁ μέγας ἀστρονόμος, *the Great Astronomer*, to distinguish it from another collection called Ὁ μικρὸς ἀστρονόμος or ἀστρονομούμενος, *the Little Astronomer*, comprising some works of Autolycus, Euclid, Aristarchus, Theodosius, Hypsicles and Menelaus. To designate the great work of Ptolemy, the Arabs used the superlative μεγίστη from which, the article *al* being prefixed, the hybrid name *Almagest*, by which it has ever since been known, is derived.

We proceed now to consider the trigonometrical work of Hipparchus and Ptolemy. In the ninth and tenth chapters of the first book of the *Almagest* Ptolemy shows how to form a table of chords. He supposes the circumference divided into 360 equal parts (τμήματα or degrees). Further, he divides the diameter into 120 equal parts. Then, for the subdivision both of the degrees and of the parts of the diameter, he uses sexagesimal fractions or, as we say, "minutes," "seconds," etc. It must not be supposed, however, that these sexagesimal divisions are due to Ptolemy; Babylonian in origin, they must already have been used by Hipparchus. Nor did the formation of the table of chords originate with Ptolemy; indeed, we know that Hipparchus wrote a treatise in 12 books on straight lines (chords) in a circle, while Menelaus (*c.* A.D. 100) wrote another in six books. Ptolemy shows how the calculation of chords is based on a few simple theorems in geometry (including the well-known "Ptolemy's theorem" relating to a quadrilateral inscribed in a circle), and these he gives in a form which for conciseness and elegance could not be surpassed; Hipparchus' method was no doubt the same, though his exposition would run to greater length.

As starting-point the values of certain chords in terms of the diameter were already known, or could be easily found by means of the *Elements* of Euclid. Thus the side of the hexagon, or the chord of 60°, is equal to the radius, and therefore contains 60 parts. The sides of the regular pentagon and decagon inscribed in a circle, which are the chords subtending arcs of 72° and 36° respectively, are found by means of propositions in Euclid's Book xiii.; expressed in terms of the "parts" of the diameter, they are found to be (nearly) $70^p\ 32'\ 3''$ and $37^p\ 4'\ 55''$ respectively. (It should be noted that the ratio of the chord subtending any angle to the diameter of the circle is the same as the ratio of half the chord to the radius; hence, expressed on this system, the chord of any angle is equivalent to the trigonometrical *sine* of half the angle.)

Now "Ptolemy's Theorem" enables us to deduce from the chords of two angles the chord of their sum or difference; the theorem is equivalent to the formulae $\mathrm{Sin}(A+B)=\mathrm{Sin}A\ \mathrm{Cos}\ B+\mathrm{Cos}\ A\mathrm{Sin}B$. Another proposition which Ptolemy gives, shows how to deduce from the chord of any angle the chord of half the angle; it is equivalent to the formula $\mathrm{Sin}^2\ \frac{1}{2}\theta=\frac{1}{2}(1-\mathrm{Cos}\theta)$. Yet another proposition gives the equivalent of $\mathrm{Sin}^2\theta+\mathrm{Cos}^2\theta=1$. As we know the lengths of (crd. 72°) and (crd. 60°), we deduce (crd. 12°); from this we deduce successively the chords of 6°, 3°, $1\frac{1}{2}$° and $\frac{3}{4}$°, and again from these (by "Ptolemy's Theorem") the chords of $4\frac{1}{2}$°, $7\frac{1}{2}$°, 9°, $10\frac{1}{2}$° etc.; we have therefore a table of chords going by gradations of $1\frac{1}{2}$°. It remains to find the chord of 1°, and thence the chord of $\frac{1}{2}$°, in order to obtain a table going by gradations of $\frac{1}{2}$°. To find (crd. 1°) Ptolemy uses a clever method of "interpolation" based on a proposition already assumed as known by Aristarchus of Samos (*fl.* 280 B.C.) and equivalent to the trigonometrical formula $\mathrm{Sin}\alpha/\mathrm{Sin}\beta<\alpha/\beta$ (where $\frac{1}{2}\pi>\alpha>\beta$). It follows from the proposition in question that (crd. 1°) : (crd. $\frac{3}{4}$°) < 1 : $\frac{3}{4}$ and (crd. $1\frac{1}{2}$°) : (crd. 1°) < $1\frac{1}{2}$: 1, whence $\frac{4}{3}$(crd. $\frac{3}{4}$°) > (crd. 1°) > $\frac{2}{3}$ (crd. $1\frac{1}{2}$°). Now Ptolemy has found (crd. $\frac{3}{4}$°) to be $0^p\ 47'\ 8''$ and (crd. $1\frac{1}{2}$°) to be $1^p\ 34'\ 15''$. Thus $\frac{4}{3}$ of the former is $1^p\ 2'\ 50''$ nearly (actually $1^p\ 2'\ 50\frac{2}{3}''$) and $\frac{2}{3}$ of the latter is $1^p\ 2'\ 50''$. Thus (crd. 1°), being both greater and less than $1^p\ 2'\ 50''$, may be taken to be $1^p\ 2'\ 50''$ as nearly as possible. Ptolemy deduces that (crd. $\frac{1}{2}$°) is very nearly $0^p\ 31'\ 25''$; and he is therefore in a position to complete his table going by gradations of $\frac{1}{2}$ a degree. No wonder that De Morgan called this exposition "one of the most beautiful in the Greek writers." Ptolemy further uses the same method of proportional increase ("interpolation") to find the chords of angles containing a number of odd minutes between 0′ and 30′, inserting in the table opposite each chord, in a third column, $\frac{1}{30}$ of the excess of that chord over the one before. One particular result is worth quoting. Since (crd. 1°) is found to be $1^p\ 2'\ 50''$, the whole circumference $=360\times(1^p\ 2'\ 50'')$ nearly, and, the length of the diameter being 120^p it follows that $\pi=3\times(1+\frac{2}{60}+\frac{50}{3600})$ or $(3+\frac{8}{60}+\frac{30}{3600})$, which is equivalent to $\pi=3{\cdot}14166$.

Trigonometry, as we have seen, was created by Hipparchus for the use of astronomers. Now, since spherical trigonometry is directly applicable to astronomy, it is not surprising that its development was prior to that of plane trigonometry.

Ptolemy obtains all that he wants in the shape of spherical trigonometry from the one fundamental proposition known as "Menelaus' Theorem" applied to the sphere, a theorem concerning the segments into which the sides of a spherical triangle are cut by a transversal. Menelaus gave the proof in his *Sphaerica*, iii. 1. Ptolemy gives it with two simple propositions on which it depends in the *Syntaxis* i. 13; the proof assumes as known the corre-

[1] The Ptolemies were not in antiquity distinguished by the ordinal numbers affixed to their names by modern scholars and represented according to the usual convention by Roman figures. This is merely done for our convenience. In the case of the later Ptolemies different systems of notation prevail according as the problematic Eupator and Philopator Neos are reckoned in or not.

sponding proposition for a plane triangle. The theorem for the sphere, though called by the name of Menelaus, must certainly have been known to Hipparchus, while the theorem for the plane triangle at least was probably known to Euclid. When Ptolemy requires the equivalent of one of our formulae in the solution of spherical triangles, he does not quote such propositions but proves them afresh each time by means of Menelaus' theorem. These various applications include the equivalent of such formulae for a right-angled spherical triangle as (1) Sin$a$ = Sin$c$ Sin$A$, (2) Tan$a$ = Sin$b$ Tan$A$, (3) Cos$c$ = Cos$a$ Cos$b$, and (4) Tan$b$ = Tan$c$ Cos$A$.

We are, above all, indebted to Ptolemy for very full particulars of observations and investigations by Hipparchus as well as of the earlier observations which Hipparchus recorded, *e.g.*, that of a lunar eclipse in 721 B.C. The work of Ptolemy is, in general, evidently based upon Hipparchus to a degree that makes it far from easy to identify Ptolemy's own contributions to the subject, except where he propounds a definite theory of the motions of the five planets, for which Hipparchus had only collected material in the shape of observations made before his time or by himself.

The "Syntaxis."—The contents of the *Syntaxis* can here be only very briefly indicated. Book i. contains the indispensable preliminaries to the study of the Ptolemaic system, treating of the earth, its spherical shape and its position in the centre of the universe, the circular movements of the heavenly bodies, the propositions required for the preparation of the Table of Chords, this table itself, the angle of obliquity of the ecliptic and Ptolemy's own method of determining it, and, lastly, so much of spherical geometry and trigonometry as is necessary for the determination of the connection between a star's right ascension, declination, latitude and longitude, and for the formulation of a table of declinations to each degree of longitude. Book ii. contains matter similar to that of Autolycus' *On the Moving Sphere, i.e.*, problems on the sphere, with special reference to the difference between various latitudes, the length of the longest day at any degree of latitude, and the like. Book iii. treats of the length of the year and the motion of the sun on the eccentric and epicycle hypothesis. Ptolemy observes that, to understand the difficulties of the question, we should read the treatises of the ancients, and especially those of Hipparchus, "that enthusiastic worker and lover of truth." He mentions here Hipparchus' discovery of the precession of the equinoxes (a subject to which he returns in viii. 2). In chapter 1, Ptolemy also lays down some general principles which are worth quoting, namely, (1) that, in seeking to explain phenomena, we should adopt the simplest possible hypothesis, provided that it is not contradicted in any important respect by the observations; (2) that in investigations depending on observations in which great delicacy is required, we should select those made at long intervals of time in order that the error due to the imperfection of our instruments may be lessened by being distributed over a large number of years. Book iv. deals with the length of the months and the motions of the moon, and Book v. with the same subject continued, the construction of the astrolabe, the diameters of the sun, the moon and the earth's shadow, the distance of the sun, and the dimensions of the sun, moon and earth. Book vi. is on the conjunctions and oppositions of the sun and moon, solar and lunar eclipses and the periods of their recurrence. Books vii. and viii. treat of the fixed stars, including precession. Book vii. ends with the catalogue (arranged under constellations) of the stars in the northern hemisphere, in which are entered the latitudes, longitudes and magnitudes; Book viii. begins with a similar catalogue for the southern hemisphere; the two catalogues include 1,022 separate stars as compared with the 850 or more included in Hipparchus' catalogue. Book viii. also describes the Milky Way and the construction of a celestial globe. Books ix. to xiii. are devoted to the planets. Book ix. begins with general remarks on the order of the planets, the difficulties in the way of framing a theory of the subject, the periods of revolution of the five planets, the different hypotheses that are possible; then (ch. 7) Ptolemy passes to the separate case of Mercury. Book x. treats of Venus; Book xi. of Jupiter and Saturn; Book xii. deals with the stationary points and retrogradations of each of the planets, and with the greatest elongations of Mercury and Venus; Book xiii. considers the motions of the planets in latitude, the inclination of their orbits and its magnitude.

The *Syntaxis* early became the subject of commentaries. For Book vi. and part of Book v. the commentary of Pappius is extant in Greek. Theon of Alexandria's commentary in 11 books was first published by Joachim Camerarius of Basle in 1538; the first two books were appended by Halma to his edition of Ptolemy. The *Syntaxis* was translated into Arabic for the Caliph al-Ma'mūn, himself an astronomer, by a translator unnamed, in 827; later it was translated by al-Hajjāj, the translator of Euclid, and again by Isḥāq b. Ḥunain (or perhaps his father Ḥunain b. Isḥāq), whose translation was revised by Thābit b. Qurra (d. 901). The first Latin translation was made from the Arabic by Gherard of Cremona; this translation, finished in 1175, was first published by P. Liechtenstein at Venice in 1515, but without the author's name. George of Trebizond made the first Latin translation from the Greek in 1451; this was revised and published by Lucas Gauricus at Venice in 1528. The *editio princeps* of the Greek text was brought out by Simon Grynaeus at Basle in 1538. The next complete edition was Halma's (1813–16). All former Greek texts are now superseded by Heiberg's edition of the astronomical works of Ptolemy (1899–1907) to which, so far as the *Syntaxis* is concerned, a German translation by Manitius has been added (1912–13).

Other Mathematical Works.—Of the other works of Ptolemy the following should be mentioned: (1) the *Analemma*, the object of which is to explain a method of representing on one plane the different points and arcs of the heavenly sphere by orthogonal projection on three planes mutually, at right angles, the meridian, the horizon and the "prime vertical." The problem is to find the position of the sun at a given hour of the day. Only a few fragments remain of the Greek text, but we have a Latin translation by William of Moerbeke from an Arabic version. This translation was edited with a valuable commentary by Commandinus (1562); and Heiberg has included it, with the Greek fragments alongside (where extant), in vol. ii. of his edition of the astronomical works. (2) The *Planisphaerium* survives in a Latin translation from the Arabic, which was edited by Commandinus in 1558 and is likewise included in Heiberg's vol. ii. The book is an explanation of a system of projection known as "stereographic," by which points on the heavenly sphere are represented in the plane of the equator by projection from one point, a pole. The pole taken by Ptolemy is the south pole. (3) Φάσεις ἀπλανῶν ἀστέρων. This is a calendar of the sort which the Greeks called *parapegma*, or a table of the risings and settings of stars in morning and evening twilight, with weather-indications (ἐπισημασίαι). (4) Ὑποθέσεις τῶν πλανωμένων, *Planetary Hypotheses*, in two books, the first of which is extant in Greek, the second in Arabic only. These works are also included in Heiberg's vol. ii.

Two separate geometrical works are mentioned by ancient commentators, (1) a single book Περὶ διαστάσεως, *On Dimension*, in which Ptolemy apparently tried to prove that there are only three dimensions in space; (2) a tract containing an attempt to prove Euclid's Parallel Postulate. The gist of the latter tract is given by Proclus in his Commentary on Euclid, Book i. (ed. Friedlein, 1873). Simplicius mentions a mechanical work Περὶ ῥοπῶν, *On Balancings*, while Suidas credits Ptolemy with three books on *Mechanics*.

The *Optics* of Ptolemy exists (save for Book i. and the end of Book v. which are lost) in a Latin translation made by a certain Admiral Eugenius Siculus from the Arabic in the 12th century. It was in five books, the last of which is interesting because it contains what is apparently the first recorded attempt at a theory of *refraction* of luminous rays through media of different densities; it deals also with astronomical refraction, of which it gives a better account than that of any astronomer before Cassini.

Lastly, Ptolemy wrote *Harmonica* in three books, a treatise on music. This was edited in Greek and Latin by John Wallis (1682); it appeared also with Porphyry's commentary, in *Johannis Wallis Opera Mathematica* (1699), vol. iii.

For further particulars the reader may refer to the article on Ptolemy in Smith's *Dictionary of Greek and Roman Biography*, vol. iii. (by De Morgan); Delambre's *Histoire de l'astronomie ancienne* (1817–21) vol. ii.; Rud-Wolf, *Geschichte der Astronomie* (1877); A. Berry, *A Short History of Astronomy* (1898); and for the mathematics to A. von Braunmühl, *Geschichte der Trigonometrie* (1900); Gino Loria, *Le scienze esatte nell' antica Grecia* (1914); and Sir T. L. Heath, *History of Greek Mathematics* (1921) vol. ii.

His Work as a Geographer.—Ptolemy is hardly less celebrated as a geographer than as an astronomer, and his Γεωγραφικὴ ὑφήγησις (or *Guide to Geography*) exercised as great an influence on geographical progress (especially during the period of the Classical Renaissance), as did his *Almagest* on astronomical. Its exceptional position was largely due to its scientific form, which rendered it convenient and easy of reference; but, apart from this, it was really the most considerable attempt of the ancient world to place the study of geography on a scientific basis. The astronomer Hipparchus had indeed pointed out, three centuries before Ptolemy, that the only way to construct a trustworthy map of the inhabited world would be by observations of the latitude and longitude of all the principal points on its surface. But the materials for such a map were almost wholly wanting, and, though Hipparchus made some approach to a correct division of the known world into zones of latitude, "climates" or *klimata*, as he termed them, trustworthy observations of latitude were then very few, while the means of determining longitudes hardly existed. Hence probably it arose that no attempt was made to follow up the suggestion of Hipparchus until Marinus of Tyre, who lived shortly before Ptolemy, and whose work is known to us only through the latter. Marinus' scientific materials being inadequate, he contented himself mostly with determinations derived from itineraries and other rough methods, such as are still employed where more accurate means of determination are not available. The greater part of Marinus' treatise was occupied with the discussion of his authorities, and it is impossible, in the absence of the original work, to decide how far his results attained a scientific form. But Ptolemy himself considered them, on the whole, so satisfactory that he made his predecessor's work the basis of his own in regard to all the Mediterranean countries, that is, in regard to almost all those regions of which he had definite knowledge. In the more remote regions of the world, Ptolemy availed himself of Marinus' information, but with reserve, and he explains the reasons that induced him sometimes to depart from his predecessor's conclusions. Among other things Ptolemy's work shows the increased knowledge of Asia and Africa acquired since Strabo and Pliny.

As an astronomer, Ptolemy was, of course, better qualified to explain the mathematical conditions of the earth and its relations to the celestial bodies than most preceding geographers. His general views had much in common with those of Eratosthenes and Strabo. He adopted from Hipparchus the division of the equatorial circle into 360 parts (our *degrees*), and supposed other circles (*meridians*) to be drawn through this, from the equator to the pole. Another set of circles was the series of parallels of latitude, and within the network of parallels of latitude and meridians of longitude it was Ptolemy's task to place the outline of the world, so far as known to him.

But at the very outset of his attempt he fell into an error vitiating all his conclusions. Eratosthenes (*c.* 276–196 B.C.) was the first who had attempted scientifically to determine the earth's circumference, and his result of 250,000 (or 252,000) stadia, *i.e.*, 25,000 (25,200) geographical miles, was generally adopted by subsequent geographers, including Strabo. Posidonius, however (*c.* 135–50 B.C.), reduced this to 180,000, and the latter computation was inexplicably adopted by Marinus and Ptolemy. This error made every degree of latitude or longitude (measured at the equator) equal to only 500 stadia (50 geographical miles), instead of its true equivalent of 600 stadia. The mistake would have been somewhat neutralized had there existed a sufficient number of points of which the position was fixed by observation; but we learn from Ptolemy himself that such observations for latitude were very few, while the means of determining longitudes were almost wholly wanting. Hence the positions laid down by him were, with few exceptions, the result of computations from itineraries and the statements of travellers, which, owing to the want of instruments, etc., were liable to much greater error in ancient times than at the present day. But, great as were the errors resulting from such imperfect means of calculation, they were increased by the permanent error arising from Ptolemy's system of graduation. Thus, if he concluded (from itineraries) that two places were 5,000 stadia distant, he would place them 10° apart, and thus in fact separate them by 6,000 stadia.

Ptolemy followed Marinus in taking, as his prime meridian from which to measure longitudes, a line drawn through the supposed position of the Fortunate islands (vaguely answering to the Canaries *plus* the Madeira group) which they placed 2½° (instead of 9° 20′) west of the Sacred promontory (*i.e.*, Cape St. Vincent, regarded by Marinus and Ptolemy, as by previous geographers, as the westernmost point of Europe). Hence all Ptolemy's longitudes, reckoned eastwards, were about 7° less than they would have been if really measured from the meridian of Ferro, which continued so long in use.

The problem that had especially attracted the attention of geographers from Dicaearchus to Ptolemy was to determine the length and breadth of the inhabited world. This question had been fully discussed by Marinus, who had arrived at conclusions widely different from his predecessors. Towards the north, indeed, there was no great difference of opinion, the latitude of Thule being generally recognized as that of the highest northern land, and this was placed both by Marinus and Ptolemy in 63° N., not far beyond the true position of the Shetland islands, which had come to be generally identified with the mysterious Thule of Pytheas. The western extremity, as already mentioned, had been in like manner determined by the prime meridian drawn through the supposed position of the outermost of the Fortunate islands. But towards the south and east Marinus gave an enormous extension to Africa and Asia, beyond what had been known to or suspected to exist by earlier geographers, and, though Ptolemy reduced Marinus' calculations, he retained an exaggerated estimate of their results.

Contents of the "Guide to Geography."—In Book i., after general explanations (cc. 1–6), Ptolemy applies himself to a correction of Marinus' results, taking account (1) of the observed (astronomical) phenomena, (2) of the various recorded itineraries of travel (*a*) by land and (*b*) by sea. Marinus had assumed as the limit of knowledge to the south a region in Africa called Agisymba, inhabited by Ethiopians and abounding in rhinoceroses, which had been reached by Julius Maternus. Modifying the data regarding this journey, Marinus placed Agisymba on the southern tropic. This made the "breadth" of the inhabited world from Thule to Agisymba 63°+24°=87°. Ptolemy, on the other hand, placed Agisymba and a certain promontory called Prason on a parallel as far south as Meroe is north of the equator; taking, then, the southern limit to be 16° 25′ S., he finds the "breadth" of the inhabited earth to be 63°+16° 25′=79° 25′, in round figures 80°, or 40,000 stades.

Marinus' estimate of the "length" of the inhabited earth overland (from west to east) may be stated in three parts, (1) from the "Fortunate islands" to Hierapolis on the Euphrates 28,800 stades, (2) from Hierapolis to the "Stone Tower" (near the Pamir?) 26,280, and (3) from the "Stone Tower" to Sera, the capital of the Serae (? inland China), 36,200 stades, making 91,280 stades in all. Ptolemy reduced the last two estimates to 24,000 and 18,100 respectively, thus arriving at a total of 70,900 stades. Reckoning 400 stades as the proper length of a degree of longitude measured at the latitude of Rhodes (36°), we have as the "length" according to Marinus 228°, which he rounded down to 225°, and as Ptolemy's estimate 177° 15′, in round figures 180°. The measurement by Marinus of the distance by sea gave 125° from the Fortunate islands to Kory, a promontory in India opposite the northern point of Ceylon, and 61° more to the "Golden Chersonese"; the distances from the Golden Chersonese eastwards to Zaba and thence nearly south to Kattigara Marinus only gave in days of sailing. Ptolemy reduced the figure

of 61° to 34° 48′, and the difference in longitude between the Golden Chersonese and Kattigara he made 17° 10′. Thus Ptolemy's total became 125° + 34° 48′ + 17° 10′ = 176° 58′ say 177°, to which he added 3° for the difference in longitude between Kattigara and the capital of the Sinae (sea-coast of China), making 180° as before.

But in thus estimating the length and breadth of the known world, Ptolemy attached a very different sense to these terms from that which they had generally borne. Most earlier Greek geographers and "cosmographers" supposed the inhabited world to be surrounded on all sides by sea, and to form a vast island in the midst of a circumfluous ocean. This notion (perhaps derived from the Homeric "ocean stream," and certainly not based upon direct observation) was nevertheless in accordance with truth, great as was the misconception involved of the continents included. But Ptolemy in this respect went back to Hipparchus, and assumed that the land extended indefinitely north in the case of eastern Europe, east, south-east and north in that of Asia, and south, south-west and south-east in that of Africa. His boundary line was in each of these cases an arbitrary limit, beyond which lay the Unknown Land, as he calls it. But in Africa he was not content with this extension southward; he also prolonged the continent eastward from its southernmost known point, so as to form a connection with south-east Asia. In Asia he took the line of coast from the Golden Chersonese as making a great bay towards the Sinae, and then proceeding *southwards* to Kattigara. The effect was to enclose the Indian ocean as one vast lake surrounded by Unknown Land. It must be noticed that Ptolemy's extension of Asia eastwards, so as to diminish by 50° of longitude the interval between easternmost Asia and westernmost Europe, fostered Columbus' belief that it was possible to reach the former from the latter by direct navigation, crossing the Atlantic.

Ptolemy proceeds (i. 19 *sq.*) to consider the question of maps and methods of constructing them. He first describes (i. 24) a method of conical projection in which the meridian circles are represented as straight lines all meeting in a certain point (a kind of north pole) and the parallels of latitude (in particular those passing through Thule, Rhodes, Meroe and Agisymba) as circles with that point as centre. (The fixed "pole," or centre of projection is as nearly as possible the vertex of the cone passing through the actual parallel circle of Thule and the equator.) A more elaborate system, in which the meridians are represented as actual arcs of circle and not straight lines, is then described (*s.* 10 *sqq.*).

Books ii. to vii. contain Ptolemy's systematic tabular location of places and features in terms of latitude and longitude for all countries. He deals in order with Europe and the Mediterranean, then Africa, then Asia, beginning with Asia Minor and passing to Palestine, Mesopotamia, Arabia, India, etc. Under Europe, the first countries dealt with are the "Britannic islands," Ireland and Albion; then comes Spain in three divisions, then Gaul in four divisions, then Germany, and so on. The arrangement of the subject-matter in tabular form, instead of being at once embodied in a map, suggests that Ptolemy's object was to enable the student to construct his maps for himself. Nevertheless, the work was from the time of its first publication accompanied by maps, which are regularly referred to in Book viii. How far the maps which are appended to the extant mss. represent the original series is a moot point. It is possible, however, that they have been transmitted by uninterrupted tradition from the time of Ptolemy.

In spite of the merits of Ptolemy's geographical work it cannot be regarded as a complete or satisfactory treatise upon the subject. It was the work of an astronomer rather than a geographer. Not only did its plan exclude all description of the countries with which it dealt, their climate, natural productions, inhabitants and peculiar features, but even its physical geography proper is treated in an irregular and perfunctory manner. While Strabo was fully alive to the importance of the rivers and mountain chains which (in his own phrase) "geographize" a country, Ptolemy deals with this part of his subject in so careless a manner as to be often worse than useless. In Gaul, for instance, the few notices he gives of the rivers that play so important a part in its geography are disfigured by some astounding errors; while he does not notice any of the great tributaries of the Rhine, though mentioning an obscure streamlet, otherwise unknown, because it happened to be the boundary between two Roman provinces.

BIBLIOGRAPHY.—Ptolemy's *Geographia* was printed for the first time in a Latin translation, accompanied with maps, in 1462(?), and numerous other editions followed in the latter part of the 15th and earlier half of the 16th centuries, but the Greek text did not make its appearance till 1533, when it was published at Basle in quarto, edited by Erasmus. All these early editions, however, swarm with textual errors, and are critically worthless. The same may be said of the edition of P. Bertius (Gr. and Lat., Leyden, 1618, typ. Elzevir), which was long the standard library edition. The first attempt at a really critical edition was made by F. G. Wilberg, and C. H. F. Grashof (Essen, 1838–45), but this only covered the first six books of the entire eight. The edition of C. F. A. Nobbe (3 vols., Leipzig, 1843), presents the best Greek text of the whole work, and has a useful index. The best edition, so far as completed, is that published in A. F. Didot's *Bibliotheca graecorum scriptorum* (*Claudii Ptolemaei geographia;* 2 vols., 1883 and 1901), originally edited by Carl Müller and continued by C. T. Fischer, with a Latin translation and a copious commentary, geographical as well as critical. *See* also H. Bradley, "Ptolemy's Geography of the British Isles," in *Archaeologia,* vol. xlviii. (1885); T. G. Rylands, *Geography of Ptolemy Elucidated* (1893); and a Polish study of Ptolemy's Germany and Sarmatia, in the Historical-Philosophical Series (2) of the Cracow University (1902), vol. xvi. (E. H. B.; C. R. B.; T. L. H.)

PTOMAINE POISONING is a popular term used to describe food-poisoning caused by toxic substances of bacterial origin. The term is misleading since the toxic substances are now known to be substances synthetized by the bacteria with or without obvious evidence of decomposition of the food rather than ptomaines, *i.e.,* organic bases, such as putrescine and cadaverine, resulting from bacterial degeneration of proteins. Examples include botulism and staphylococcus food poisoning, a violent but usually nonfatal type of poisoning, generally associated with the eating of éclairs and cream puffs. (*See* FOOD POISONING.)

(F. L. A.)

PUBLIC ADMINISTRATION is the application of a policy of a state through its government. Policy is given general legal formulation by legislative institutions in statute law; but there then remains the defining of that law for specific application. A statute is the product of a law-making agency which is not always in session, whose members are usually selected to represent general attitudes and opinions rather than to possess expert knowledge. After a statute is adopted, rules are needed for its detailed application in the enforcement of both the statute and rules to the situations it was designed to affect. Thus, a statute adopted to facilitate traffic may authorize in general terms the regulation of the movement of motor vehicles, by specifying reasonable speeds on public streets and highways with due regard to density of population, location of schools and hospitals and the existence of intersecting streets, and also will probably provide for some agency in continuous operation, and presumably with knowledge, experienced personnel and material equipment, with power to translate the general objectives into more specific regulations (*e.g.,* as to coming to a full stop at main arteries or obeying light signals) and to enforce the statute and regulations, with penalties for those who violate them.

Thus, public administration is interrelated with public opinion in that it follows upon the decision of the political leaders to undertake or abandon collective activities or to support or accept laxity in the enforcement of laws; with the legislative process in that effective administration may be rendered difficult or impossible by faulty legislation, and also because the experience and knowledge of the administrative agency are of value to the lawmaker, just as its possible corruption or ignorance may mislead or handicap him; and to the judicial process since the action of the administrator may be challenged in the ordinary or in special courts by a citizen, and the administrative agency may be required, under the terms of a particular statute, to apply to the courts for judicial action against those presumed by the agency to be violating the law. While there is a theory that administration and

policy are two separate processes of government, in fact they are constantly merging and interfused. This is because policy-making is inadequate if there is no consideration of the means for making the law effective, and administration of a general objective raises questions of choice, and hence policy, in any specific situation. It is a policeman who arrests a traffic violator, and not a statute, which remains within the covers of a book.

Administration and Policy.—The problems of public administration reflect, therefore, these interrelations with opinion, legislation and adjudication. They also reflect the stage of civilization, the time, place and environment generally of the particular political unit. Thus, at the top of the administrative structure is an official who can speak for, and to, the dominant political power of the society. This need for making the administrative agency subservient to the original intent for which the activity was authorized and the political forces, party or factional or personal, which took the responsibility for the legislation authorizing the program explains why the headship of an administrative agency, at least of national agencies, is generally a politician and nonexpert. He is chosen because he must interpret to the experts what the judgment of those in political power is, and to the politicians and the lay public what the more technical considerations that will affect their political objectives are. The greatest quantity of public administration is in the substantive functions of government such as those of public safety and order, public health, public works, education, the development of natural resources, the facilitation of transportation, the care of the handicapped and the facilitation and regulation of finance, business and industry. Roads and harbours are built. Social insurance payments are made. Forests are guarded from fire or disease. Each field of activity has its accumulated technical knowledge, personnel, forms of organization and procedure, vocational and professional ties, associations and corporate interests, loyalties and issues. For any particular jurisdiction in which a number of these functions are administered, the problem of allocating available revenue to each, of determining priorities and of co-ordinating the application by each agency of policies in which account should be taken of what other agencies are doing is one of the most important responsibilities of the highest administrative authority. At this point in the structure and process of government there is a meeting and mingling of political policy, general management and the conduct of the particular functional departments.

MANAGEMENT

Direction and General Staff.—The heads of the administration in any jurisdiction have a double responsibility of helping to formulate legislation on the one hand, and of directing and co-ordinating the administrative agencies to carry out the authorized policies on the other. This latter task becomes difficult in those stages of civilization in which many functions are undertaken through government since it includes the proper assignment of activity to organization units and the co-ordination of several organization units, each of which has some necessary share in the activity but each of which is also likely to develop its own personality, attitudes and jealousies. Hence, the top administrative policy group, in modern times often called a "cabinet" from the meeting place in the king's quarters (hence his "cabinet council"), and its chairman or chief—prime (*i.e.*, "first") minister, premier or president—need to have the problems presented to them analyzed by persons of integrity, competence and experience. This has come to be called "general staff service" from the influential and famous Prussian general staff. Elements of this important step in the administrative process are to be found wherever government has been effectively used. Thus, planning, inherent in the process of formulating policy, becomes essential also in its wise application, whether in the conduct of war, the prevention of epidemics, the facilitation of transportation or the relief of destitution.

Auxiliary Services.—The responsible political chiefs of administration have been found by widespread experience to need other aids to ensure economical and efficient application of policy. These are agents for obtaining and facilitating the best use of personnel, physical materials and equipment, architectural and engineering services and finances. Since such tools are aids both to general direction and to the operating officials (who are on the front lines in the field, building highways, waging war or constructing irrigation projects), they are frequently called the auxiliary services.

Characteristic auxiliary services are those which recruit and examine applicants for government employment, budget offices which prepare estimates and supervise expenditures authorized by the appropriating and taxing authority, purchasing agencies which prepare specifications describing needed materials, purchase them and inspect, store and deliver them and printing, architectural and construction agencies. They are also frequently known as the "housekeeping services" since they perform them for the various operating agencies. Their justification lies in their ability to perform for all the operating departments these specialized tasks more effectively and economically, and to maintain general standards of salaries, prices and procedures.

There is inevitably some clash between such auxiliary agencies with their responsibility to the administrative chiefs for over-all policy, and the particular operating agency with its enthusiasm for and special knowledge of its own field, and hence resentful of controls that are often called "red tape" (used historically to tie up documents for filing). To the operating official, there looms the threat of what is termed in the British civil service the "treasury mind"; its cousin is found in all large organizations in all times and places. To the official zealous in pressing forward his project, the scrutiny of some part of it by another agency which has no immediate apparent responsibility for the success or failure of the project or its initiator, is irksome. The auxiliary or general staff official, however, is equally impressed with the necessity of relating the single project to the other activities of the government, of bringing the enthusiasm of the official within the bounds and standards which the accumulated experience indicates as effective norms and economical expenditures.

Personnel and budget policies illustrate the fact that auxiliary and general staff services (which intermingle through day-to-day activities) are more than narrow technical matters. They are of central importance in the operation of any political system.

Personnel.—Long and varied experience in all parts of the world demonstrated the necessity, for effective administration, of a reservoir of accumulated knowledge of the administration of a function—a knowledge that can be obtained only from persons of ability and integrity who have been given an opportunity for a career, within the appropriate general political, legislative and judicial controls, in administration. That is not the only reason why spoils systems, wherever they exist, have been disastrous (except in situations in which they may have served as alternatives to more costly revolutions). Their primary evil is that they undermine any use of parties and legislatures as reasonably accurate instruments of recording political sentiment and ideas, since they replace the relationship of agency for the public by agency for the chief spoilsman and turn responsible public affairs into irresponsible private rackets. Their administrative evil is that they prevent the accumulation of knowledge that only experience can give. No person of ability and integrity would be willing under spoils conditions to seek a satisfying career, and inevitably the agency sinks in effectiveness and in public confidence and any public objective is lost. Even in revolutionary conditions a new government is generally reluctantly forced to rely upon such officials of experience and knowledge as it can find for carrying on those services necessary for the safety and welfare of populations—especially in a society partly urban. The knowledge referred to here is not only the knowledge of a substantive problem, such as preventive medicine, for example, or highway construction, but the more subtle knowledge for which long experience inside the working of human institutions is required. This is the knowledge of who knows what, of how to use procedures and codes to hasten or delay business, of how to avoid arousing group and individual jealousies, of "moving through the correct channels" and of winning the agreed consent of all those necessary to a policy. The term "bureaucracy" is sometimes given, often in

disparagement, to governments in which the "permanent" or "career" officials exercise or condition power. Such a dependence on officials, however, is inevitable and necessary in governments exercising many and interrelated functions.

The selection and training of civil servants has therefore been an important problem of government since early times. The system of widespread recruitment on the basis of examinations in the classics was a feature of the government of China for hundreds of years. The training of officials for the administrative posts in the mediaeval papacy and empire included courses in such universities as Bologna and Naples. The palace school of the Ottoman empire was the nursery of the civil, military and naval officer classes. The ruling families of the German principalities founded universities in which their civil servants (often jealously opposed by the feudal nobility) were educated. In both 19th-century Germany and France, the rise of a larger and more varied civil service was accompanied by the development of opportunities for secondary, university and specialized education that reflected also the enlargement of the middle class. The École Libre des Sciences Politiques in Paris and the development of careers in municipal administration in Germany illustrate these tendencies. The Trevelyan-Northcote report on the civil service in Great Britain in 1853 was influenced by such educators as Benjamin Jowett of Balliol and John Stuart Mill. The expansion in the functions of government in the United States prior to World War I created an interest in the education of administrators which revived strongly with another expansion in the decade 1930–40.

In general, educational qualifications for administration reflect the general social conditions of the time and place and the classification of the positions to be filled. A more fluid and democratic society opens its opportunities for secondary and higher education widely and this tends to prevent the formation of a special official caste sheltered by inherited privileges. The "single-party" system of government tends to create a new form of special privilege dependent upon party allegiance. But in all systems, a job analysis will reveal the need for continuous education after entrance if there is to be an adequate supply of recruits for the higher directive and technical positions. Hence, the questions of "in-service" training, of educational leave and the recruitment through promotion and from outside the service are as much the subject of discussion and experiment as the older question of "pre-entry" training. At this point the interest of students of public administration turns to developments in education and psychology generally as well as to experience in industry and commerce.

The Budget.—The outstanding instrument whereby the total program of a government for a given period of time is set forth by organization unit, types of expenditure and in other detail is the budget. In most states (notably Great Britain, which contributed most to its development as an important tool of government) the budget originates in the executive departments in the form of estimates of proposed expenditures and the revenues to cover them, is submitted to the legislature for investigation, amendment and legal authorization and is then administered by the budget and other finance agencies. The budget process ends with an audit to determine whether expenditures have been properly based upon the legal authorization—an audit frequently made by an agency of the legislature, or otherwise independent of the administrative chiefs. The budget as authorized by the lawmaking process is thus inevitably the total plan for all the activities of the government for the next fiscal period (generally a year), including the provision for personnel and materials. The long evolution of representative government has centred largely in the development of a good budget system, including "the control of the purse strings" by the elected representatives of the people; that is, the submission to them by the executive (usually in name, at least, by the king) of the proposals for expenditure, taxation and loans and the scrutiny and amendment, acceptance or rejection of these by the representatives, sometimes with the aim and result of forcing the king's administrative chiefs and policy advisers from office. The cabinet system, whereby the chief executive officials must possess the support of the majority of the legislature, thus had its origins; while the importance of legislative control over expenditure, and of the appropriation process, is illustrated also by provisions concerning them in the constitution of the United States and in the development of government everywhere.

The Planning Process.—The function of cabinets and chief executives as well as the heads of large departments in the preparation of policy for submission to the legislative authority became complex and difficult with the widening and interdependence of the functions of government. Thus, in a metropolitan area the design of streets and highways, water supply, parks and schools is dependent upon population, industrial, commercial and technological trends as well as changes in the ideas held by citizens as to standards of living. As a result, the usual budget processes are sometimes supplemented by special staff agencies for investigation and analysis, or by regular and continuing agencies to which the term planning is applied. Planning as an inherent need in the structure and process of administration was diagnosed and recommended by Frederick W. Taylor in his pioneer work in scientific management, although, as noted above, it has been called into existence in some form, as in military affairs, wherever thought has been applied to the problem of the improved preparation of programs.

The "mercantilist" and "cameralist" policies of the early modern state caused the rise of career civil services and methods of training for them. A similar increase in collective services, whether in the U.S.S.R. with its elaborate central, regional and local programs of state action, or a cut-over region of sparse population requiring long-time land policies in the United States, or a great urban agglomeration such as London, Bombay or New York, made desirable and necessary the establishing of planning agencies. Their function is to gather and analyze data concerning the problems of the political organisms they serve and to submit reports on their studies to the political chiefs, the legislatures and the electorate. Sometimes these agencies are also given some operating responsibility and power. Thus, they may be given the enforcement of controls over land use or authority to determine priorities in the allocation of resources to projects. Whether such planning agencies should be exclusively research and advisory in their functions or should have in addition operating functions and powers is a subject of controversy among students of administration. It is agreed, however, that there should be close and sympathetic working relations and an interchange of personnel between them and the budget and other general staff and auxiliary services and the substantive departments.

It may again be stressed that the budget should reflect, as the most comprehensive record of operations proposed for the next fiscal period, the result of the planning process as registered in the working and financial program which the chief executive and his associates are responsibly proposing to the highest lawmaking body of the jurisdiction. Thus, the estimates which are proposed will presumably be supported and justified by the analyzed data. Viewed in this light the planning process in administration is not, as sometimes argued, in opposition to legislative authority but essential to it. A legislature, in fact, may rightly demand that such preliminary collection and analysis of data be undertaken by the executive to ensure a better preparation of proposals placed before it. The use of the fiscal policy of a government to affect general economic conditions by its influence on investment and employment increases the need for careful planning of the estimates.

Internal Operation.—The directive, general staff and auxiliary agencies exist to serve the substantive or operating departments, and it is through them that the functions of a political system are applied. In these basic substantive departments there is a division of labour reflected in an organization of units whose heads are related in some line of responsibility and power. The system may be recorded on organization charts and in standard specifications for every position whereby the duties, qualifications, rates of payment and official titles are set forth. The relation of the different levels, the flow of correspondence, reports, memoranda and dockets of official business and the arrangements for conference between units (bureaus, divisions, sections, branches, regional offices, etc.) may also be guided by written and official codes of procedure. The procedure to be followed in relations

with the public generally by correspondence, interview, investigation or inspection, or hearings of an informal or formal type, tends to become standardized and codified. This results in a standardizing of practice that leads to charges of red tape, bureaucracy and the stultifying of initiative. A failure to regularize procedures, however, leads to criticisms of unfairness, capriciousness and abuse of power and an invitation to corruption. The interests affected by the function administered are generally organized in economic or professional associations. Sometimes representatives of these interests are brought into official participation in the administrative process through committees advisory to the agency or committees given some power of administering the program for which the agency is ultimately responsible. At its extreme, such a system might be termed "the corporative state" so much discussed in political theory in recent decades, although never actually embodied in any completeness.

Among the groups involved in the administrative process with some special interest or emphasis of their own are various organizations of the civil servants. Since the number of civil servants in a modern state may be great, collective action in the effort to affect rates of pay and conditions of employment generally developed despite opposition. In some systems, a regular procedure was established (as notably in the "Whitley councils" in the British civil service) for consultation between the directive and personnel officials and the representatives of the civil service organizations.

Thus, the maintenance of some balance in modern administration between the interests and attitudes of legislatures, parties, executive leaders, auxiliary service agencies, interest groups affected and the civil servants themselves is no easy task. The systems appear sprawling, cumbersome and unwieldy and too far removed from the situation from which the call for governmental action originated. Internal operation is complicated further by the relating of decisions taken at the centre to the varied conditions in the field.

The problem of clarifying and explaining the complex task of a department led to increased interest in methods of reporting. Experiments in the use not only of printed and illustrated reports but of the motion picture, the radio, television and direct face-to-face discussion and conference were undertaken. Legislatures are inclined to oppose these on grounds that they may become an alternative to the party system as a means of consulting public opinion and may stimulate public pressure for legislation favourable to the agency employing them.

The problems of internal operation in public administration are in many ways akin to or identical with those in other social institutions, including industry and commerce. The comparative study of institutions, including the relation of individuals in the smaller face-to-face groups, brought scholars and administrators together from many fields to share experience and plan and conduct research. Psychologists, personnel managers, anthropologists, sociologists and many other workers find a common field in what is given various names, such as social relations, human relations or the study of the human group. A special challenge was raised by growth of international programs and agencies in which the problems of a substantive field such as health are complicated by the need for co-operation by peoples of different cultures. The training of administrative personnel for such programs began to reflect the new emphasis on human relations, and also the area or regional studies whose origins may be found long ago in the policies of missionary societies and colonial offices, as well as in World Wars I and II.

DECENTRALIZATION AND DEVOLUTION

Whenever the size in area and population of the jurisdiction served by an administrative system is large, the adjustment of general policies and standards to varied local or otherwise specialized circumstances constitutes a major problem. If too great freedom is given to officials to adjust standards to the particular instance, effective general legislation becomes difficult or impossible, and programs may get distorted and special interests may injure the general good. Partisan, sectional, factional or other special favours and corruption may follow. And yet the particular knowledge of the persons whose life work is in an industry, or is concerned with a commodity or profession, or with a particular region or locality, should be employed if a policy is to be wisely administered. The states of the world have in all times, from ancient China or the Roman empire to the present, attempted to meet this problem either by leaving or giving some measure of local self-government to local areas, or by creating regional units in their central administrative agencies to which some discretionary powers for making decisions within the general rule for problems arising within the area are given.

A variant of the same principle is the assigning of powers for the administration of a statute or general policy of the state to a professional, commercial or industrial association or representatives of such interests. Thus, we may find, as in the Germany of the Weimar republic, not only *Länder* or member states within the Reich but local units within them and also an economic council. Similarly, in Great Britain, which we ordinarily think of as a unitary or relatively centralized state, there are county councils, rural district councils, boroughs and also boards possessing statutory powers in the steel industry or dealing with a commodity such as milk or bacon. In the United States the same problem of relating general policies to the particular situation confronted the constitution makers in 1787, resulting in a federal system, but persists to the present and indeed becomes more complicated as new units such as soil-conservation districts or local housing authorities are created with direct relations with national agencies.

The grant or taking of power by economic groups was advocated perhaps more strongly at about the time of World War I, and a political theory designated "pluralism" or "functionalism" had a period of success. It was indeed supposed to have been reflected in the doctrines of the Russian bolshevists and the fascists in Italy, as well as in the creation of economic councils in France and Germany. Probably local circumstances and situations in the latter two states, just as in the establishment of the National Recovery administration in the United States, with its industrial codes, had a much greater importance, while the Russian and Italian systems quickly revealed themselves as highly centralized single-party controlled governments struggling to secure and retain power and therefore in no position to yield power to regional or commodity or other groups except as forced by circumstances to do so.

The point is, however, that circumstances (*i.e.*, the increasingly complex nature of the activities that go to make up modern economy, the strong pull of neighbourhood and region and all kinds of provincialisms and the necessity to achieve political as well as administrative success for policies) do press for the adjustment of general policies to particular situations and do require the consultation at least by administrators with persons and organizations affected by those policies. It is characteristic of modern legislation affecting industry in some states, for example, that councils on which employers and employees, or members of a profession, are represented, participate in drafting rules and regulations under the act.

Relations of a national or central authority with provincial and local governments are made more complicated by the rise of metropolitan cities that spread over several separate political jurisdictions, the inequality of tax resources of local units, the pressure for national minimum standards of public services and the interdependence of economies. A partial answer to these conditions is found in the grants distributed from national funds to local units on condition of meeting certain required standards, with resulting inspection from the centre, generally entitled "grants-in-aid," and in the employment of officials of one level of government for enforcing the laws of another. The relation of levels of government remains, however, as one of the most difficult and perplexing problems of public administration.

CONTROLS AND STANDARDS

Obviously public administration is certain to be subjected to criticism in part because the objectives sought are disliked or the methods employed are viewed as unjust or inefficient or corrupt.

Over the centuries various devices for its control have evolved. These efforts are designed to confine it to the political objectives for which a particular administration is established, which we may call political control; or to ensure most economical and efficient methods, which we may call executive control; or to ensure observance of the accepted rules of fair conduct as understood by the particular society to apply to the relation of officials with the public, which we may call judicial control; but they necessarily intermingle, and broadly speaking, with the rise of representative government, a somewhat stronger emphasis inevitably was placed in most states upon political control. This is exercised through making the chiefs of administration politically responsible either to the legislature or to the electorate by some form of popular election.

Probably the most famous example of the evolution of political control is the wresting of power from the king and its allocation to a committee of party leaders representing a majority of the house of commons in Great Britain. This system, called "cabinet" or "parliamentary" government, was a model for most states to follow (with varying success). The U.S. "presidential" or "congressional" system makes the chief executive, except in city manager-council government cities, responsible to the electorate. Both systems, however, operate through parties; and at times the British prime minister takes on presidential attributes, and the U.S. president similarly at times plays a role in relation to congress somewhat akin to that of the prime minister in relation to the house of commons.

The more detailed devices of party and legislative control vary greatly; but most legislatures employ committee investigations of administration, scrutiny of budget estimates, the control over expenditure and audit and frequently the questioning of executive chiefs on the floor as well as in committee. These matters are usually topics of discussion at meetings of the Interparliamentary union, the conference of delegates from the legislative bodies of the states of the world.

Executive control is exercised through general staff and auxiliary services as described, and in modern complicated and large structures necessarily employs the techniques of the formulating of general standards, as of personnel, enforced by special auxiliary agencies. Probably the most important control is wielded through the analysis of budget estimates by the central financial control agency of the chief executive and his colleagues.

The struggle of legislatures first for independence of the monarchy and later for supremacy is paralleled historically in many states by a similar effort of the courts for independence; and in some states, notably the United States, the system of written constitutions and a federal distribution of powers has been the basis upon which has been constructed the exercise of judicial review not only of the acts of officials but of the constitutionality of the statutes whereby the officials may have justified their actions.

In many states, notably those influenced strongly by the traditions and precedents of the Roman law, a series of special courts evolved in which controversies involving official acts of civil servants are adjudicated, and the resulting case law, as in France, constitutes an important part of the public law. Administrative law is thus everywhere a branch of public and constitutional law that grows in importance as the extent and complexity of the functions of government increase. Questions of the competence of the authority, the adequacy and justice of the procedure, the extent of the grant of discretionary power, the adequacy of the evidence in support of the administrator's action and the finality of the administrative decision are typical issues. The study of comparative government, and in particular of comparative jurisprudence and administration, is resulting in a greater familiarity on the part of scholars and of some practitioners with the similarities between different systems and a tendency to discover devices in one system that may usefully be adopted in another. Many precedents and theories framed long ago during the struggles with monarchy are being reappraised in the light of the contemporary complexities of administration.

While legislative, executive and judicial controls are of basic importance, it should not be forgotten that in the daily life of the administrator his own knowledge, character and sense of personal and professional responsibility, constituting a series of inner standards and checks, are probably more immediately and intimately influential. Hence, the rise of professional organizations, of research, of in-service training, of journals devoted to administrative questions have increasing importance and constitute a professional control which has operated, indeed, at times in all societies.

The increasing association of citizens through advisory committees with administration, and their sharing in fact with the exercise of some of the discretionary power in rule making, and the necessity for many types of administration of winning the understanding if not the active support of the citizen, characteristic increasingly of many types of administration, is another less recognized but important control over public administration. Many statutes and programs involve matters touching intimately the lives of great numbers of citizens; it is impossible to enforce them (as, for example, systems of social insurance or of highway safety or disease prevention) without extensive efforts to acquaint citizens concerning them. But in that process, the official is often educated himself as to attitudes, habits, capacities and problems of those whom he is supposed to serve; he is probably less concerned with possible legislative, judicial or even higher executive action regarding his work than with the people and problems immediately at hand. In this sense, we may consider administration as moving into a stage in which a two-way educative process is discernible; and while it may seem a far cry from the edicts of ancient rulers, one suspects that even they, too, had sometimes to consider how far they could go with subjects unaware of or opposed to their aims and measures.

PUBLICAN: *see* LICENSED VICTUALLER.

PUBLICANI, the name given in ancient Rome to a body of men who either hired state property or monopolies to farm for their own profit or bought for a fixed sum the right to farm the taxes due to the treasury from the public land in Italy, or the land held by Roman subjects in the provinces. In early times the senate entrusted to officials the control of the sale of salt (Livy iii, 9), and it was a development from this that the state, instead of appointing officials to manage its monopolies, let out those monopolies to individuals. A regular system was established by which the censors who held office every fifth year placed the sources of public revenue in the hands of individuals or companies, who on payment of a fixed sum into the treasury, or on giving adequate security for such payment, received the right to make what profit they could out of the revenues during the five years elapsing before the next censorship. The assignment was made to the highest bidder at a public auction. The same system was applied to the public works, the *publicanus* in this case being paid a certain sum, in return for which he took entire charge of a certain department of the public works. That this system was well established at the time of the Second Punic War is assumed in Livy's account of the various offers made by the wealthier class of citizens to relieve the exhausted treasury after the battle of Cannae (216 B.C.). On the one hand we have companies offering for branches of the revenue a price which was calculated rather to meet the needs of the state than to ensure any profit for themselves (Livy xxiii, 49). On the other hand individuals are represented as undertaking the management of public works on the understanding that they would expect no payment until the conclusion of the war (*ibid.* xxiv, 18).

Since wealth was a necessary qualification for the post, and wealth at Rome became more and more confined to the commercial class, the *publicani* became identical with the class of capitalists and traders. This was distinct at Rome from the senatorial class, which was excluded from it by definite enactment (*see* SENATE), and, except in face of common danger, was often hostile to it. It was in their capacity of *publicani* in the wealthiest provinces that the capitalist or equestrian *iudices* (*see* EQUITES) became a menace to the provincial governors who represented the senatorial power. When the demands of the equestrian party determined the policy of the state we can trace the interests of the *publicani* as

the motive of its action. Thus the fate of the Roman business men in Cirta led to the Jugurthine War in 112 B.C.; the disorganization of Asiatic commerce by the pirates led the *equites* to support the proposal to confer extraordinary powers on Pompey in 67 B.C.; and the quarrel over the contracts for the taxes of Asia in 60 B.C. led to the downfall of the senatorial party.

Under the empire the *publicani* were subject to close supervision. The name appears as "publicans" in the New Testament.

PUBLIC AUTHORITIES PROTECTION ACT. This British statute was enacted in 1893 and represents, to some extent, a consolidation of previous statutes limiting the time within which actions may be brought against "public authorities," including thereunder local government authorities, justices of the peace and, it has recently been held, Crown servants also. It goes, however, far beyond the particular statutes which it proposed to "generalize and amend" in that it imposes new and most invidious restrictions on any plaintiff who seeks to sue a "public authority" for a wrongful act. These are dealt with in the article *Petition of Right*. The statute which requires all such actions to be brought within six months does not, however, extend to actions for breach of contract, as distinct from tort by public authorities. Such actions are subject to the ordinary period of limitation prevailing in actions between subject and subject, *i.e.*, private persons, namely six years. The Act has been described as "intended to protect public bodies from expense when they are unsuccessfully sued in respect of acts done or omitted to be done in the exercise of statutory powers or duties" (Lindley M.R. in *Fielding* v. *Morley Corporation*, 1899, 1 Ch. at. p. 4). The description is inadequate, however. As is shown elsewhere (*see* PETITION OF RIGHT), the statute operates in practice to deter persons wronged from suing at all, and penalizes them on technical grounds with special costs for suing even where they would have had an undoubted cause of action had the action been brought within the prescribed period of time. The "protection" afforded by the statute extends not only to any wrongful acts done "in pursuance or execution or intended execution" of a statutory duty but also in pursuance of any "public" duty or authority. All these terms, as also the question whether the act complained of arises out of a constructual relation or not, whether it occurred in the execution of a "duty" or merely in the exercise of a "power," as also the relation between a "continuing" act and "continuous" damage, have been the subject of endless litigation. The "protection," in other words the privilege, conferred by the statute extends not only to a public authority but also to all officers and servants acting under its orders. (J. H. Mo.)

PUBLIC HEALTH. The term as used in Great Britain connotes in the broad sense principles and measures which aim at promoting and safeguarding the health of the community in contra-distinction to those which are concerned in the main with the treatment of declared disease in the individual. For public health in the United States *see* Section II.

I. GREAT BRITAIN

The original conception of public health requirements in Great Britain was fairly simple—the improvement of drainage and sewerage, the provision of adequate and satisfactory water supplies, scavenging, the isolation of cases of infectious disease. Then came the supervision of housing conditions, the clearance of slum areas, the provision of open spaces and the efforts to provide a cleaner atmosphere. More attention is now paid to food supply as in provision for the analysis of food-stuffs, in the supervision of the production and distribution of milk, the elimination of tuberculosis from dairy cattle, the control of slaughtering and inspection of meat, the inspection of premises used for the preparation or storage of food. Action regarding infectious disease has passed beyond isolation of the individual attacked and disinfection of premises to the supervision of contacts and careful investigation of possible sources of infection, and the system of port sanitary control has been placed on a scientific basis and all these matters, as they develop, are referred to and accepted as public health measures. The present century has witnessed public health development in other directions. There has been the growth of activities which aim at the conservation of young life, the early treatment of physical defects, and the inculcation of healthy nurture with the object of ensuring healthy citizens. These have found expression in the Maternity and Infant Welfare and the School Medical services. Public provision has been made for the treatment of certain diseases which, from their economic or social importance, can best be countered by organization on a communal rather than an individual basis, such as tuberculosis, venereal disease, and the crippling effects of infantile paralysis. (*See* also MATERNAL AND CHILD HEALTH.)

The statutory authority for this work is furnished by various Acts of Parliament. The charter of public health administration is the Public Health Act of 1875 which has been amended by the Acts of 1890, 1904, 1907 and 1925. Other important health enactments are the Public Health (Water) Act, 1878, the Infectious Disease (Notification) Act, 1889, the Infectious Disease (Prevention) Act, 1890, the Open Spaces Act, 1906, the Milk and Dairies (Consolidation) Act, 1915, the Public Health (Smoke Abatement) Act, 1926, and various provisions in the Housing Acts. The later developments of public health have their basis among other enactments, in the Education (Administrative Provisions) Act, 1907, the Education Act 1921, the National Insurance Act 1911, the Venereal Disease Act, 1917, the Maternity and Child Welfare Act, 1918, the Public Health (Tuberculosis) Act, 1921, and in various regulations framed by the Ministry of Health.

The foregoing refers to legislation for England and Wales. The Scottish and Irish Acts, though similar in objects and results are usually different in form and adjusted to the national conditions of those countries.

Central Authorities.—The authorities concerned in the administration of public health are central and local. In England and Wales the chief central authority is the Ministry of Health. This department had its origin in certain movements which can be traced back to the beginning of the 19th century. Interest of the State in the physical health of its citizens is a comparatively modern development, and may be traced broadly to four chief causes; first, to reaction against the anarchy of the Industrial Revolution; secondly, to the gradual development in the latter part of the 18th century of a humanitarian spirit, as evidenced by the work of John Howard in the reform of prison life, the movement for the abolition of the slave trade, and the efforts of Sir Samuel Romilly and others to infuse a spirit of humanity and common-sense into our penal laws; thirdly, and probably the most important, to the appearance for the first time of Asiatic cholera in Europe and the threat of its invasion of England; and fourthly, to the establishment of the central Poor Law Commission in 1834.

The first Secretary of this Commission was Mr. Edwin Chadwick, one of the great public health pioneers of the 19th century. He forced upon public notice the importance of sickness and ill-health in the production of poverty, and insisted that the prevention of disease was one of the first duties of the State. Largely as a result of his efforts the first Central Health Department, the General Board of Health, was established, prematurely as it afterwards proved, in 1848. Ten years later this board was dissolved and its duties distributed amongst other offices, but in 1871 they were gathered together again and, with those of the Poor Law Commission, transferred by Act of Parliament to a newly-created department, the Local Government Board. This board remained for nearly 50 years the principal central authority for public health, until in 1919 its functions, together with other health functions, such as health insurance and the medical inspection of school children, which had come to be entrusted to separate central authorities, were transferred to the Ministry of Health. The Ministry of Health Act, 1919, by which the Ministry of Health was established, had as its purpose the prevention of overlapping and competition between certain of the central departments by bringing the health services which they administered into a single department under a Minister of Health.

Among other central authorities concerned with questions of

public health are the Medical Research Council, a Committee of the Privy Council, which co-ordinates research on medical subjects, the Board of Trade, which is responsible for the health services of the mercantile marine under the Merchant Shipping Acts, the Ministry of Agriculture and Fisheries which has certain powers and duties relating to the production of food and milk, the Ministry of Pensions which has the care of disabled officers and men after they have left the naval, military and air services, and the Home Office, in respect of industrial hygiene control under the Dangerous Drugs Acts, etc.

Local Authorities.—The local authorities charged with the administration of public health services are the Rural and Urban District Councils, the latter including the Metropolitan, Municipal and County Borough Councils. These bodies are assisted in the discharge of their duties by a technical staff consisting of the Medical Officer of Health and the chief Sanitary Inspector, whom they are required by law to appoint, together with what additional assistance may be necessary. In the smaller districts the duties are sometimes performed by a part-time Medical Officer of Health who is also engaged in general practice, and by a whole-time Sanitary Inspector. In the larger cities the staff of the Public Health Department may number several hundred persons. The Poor Law Guardians have important health functions in relation to the medical care of the poor, and are also responsible for the administration of the Vaccination Acts.

County Councils other than County Borough Councils are not health authorities within the meaning of the Public Health Acts, but they have been given important duties under the Isolation Hospitals Act, under the Tuberculosis Regulations, the Maternity and Child Welfare Act, the Venereal Diseases Regulations, and also in regard to school medical inspection, and the tendency of present-day policy is gradually to shift much of the responsibility for these and similar personal health services from the smaller urban and rural authorities to the County Councils, and thus, by increasing the strength and efficiency of local administration, to diminish the need for detailed control and interference by the central departments.

Public Health Personnel.—The first local authority to appoint a salaried Medical Officer of Health in Great Britain was Liverpool in 1847. In 1848 the Corporation of the City of London appointed Dr. (afterwards Sir) John Simon to be its Medical Officer of Health. The larger cities followed and in 1872 the practice had become so general that the Public Health Act of that year made it obligatory on every urban sanitary authority to appoint a Medical Officer of Health. The Public Health Act of 1875 extended this obligation to all local authorities, both urban and rural.

At first no special qualification was prescribed, but in the Local Government Act of 1888 a clause was inserted requiring that after the 1st of January 1892 every Medical Officer of Health of a County or of a district containing a population of 50,000 or more inhabitants should be not only legally qualified in medicine, but also be the registered holder of a Diploma in Sanitary Science, Public Health or State Medicine. By an Order issued by the Ministry of Health in 1922, this requirement was extended to all Medical Officers of Health, so that to-day no candidate is eligible for such an appointment unless he holds a Diploma in Public Health, except by special dispensation of the Minister of Health. The Sanitary Officers Order of 1922 also laid it down that every Sanitary Inspector appointed by a local authority should possess a recognized qualification in Sanitary Science.

In the brief survey which follows reference is made to some of the more important matters dealt with by local public health authorities.

Vital Statistics.—Vital statistics furnish a measure of the influence of various conditions and occupations on the health of the population and a means by which the value and efficacy of the ameliorative and preventive action taken by local health authorities can be assessed. Every Medical Officer of Health is required to furnish each week to the Registrar General a return of all cases of infectious disease notified in his district. These returns, together with those supplied by the local registrars of births and deaths, are the material on which the Registrar General bases his Weekly Report, and also his Quarterly and Annual Statistical Surveys. This information is supplemented by Annual and special reports of Medical Officers of Health and from the results of investigations by Medical Officers of the Ministry of Health and by other departments and voluntary bodies interested in the physical, industrial and social welfare of the people.

Environmental Hygiene.—Long before the discovery of bacteria and their relation to disease, sanitarians recognized the close association of dirt and pestilence and the importance of cleanliness in the prevention of infection. It is difficult to believe that elementary health services such as the provision of a public water supply, drainage, sewerage and sewage disposal, the regular removal of house refuse and the cleansing of streets, which are to-day accepted as indispensable to civilized life, were practically unknown through the greater part of England and Wales less than a century ago. These services are now regularly undertaken by all local sanitary authorities. Control is exercised over building to ensure freedom from dampness, adequate lighting, ventilation, drainage, closet accommodation in houses intended for human habitation. Many of the larger towns have long since reached out beyond these elementary objectives, undertaking other services which have, directly or indirectly, a beneficial effect on the welfare of the community—the provision of cheap transport which has helped to overcome the housing difficulty, the provision of gas and electricity which has lessened labour in the homes and contributed to a cleaner and more wholesome atmosphere, the provision of parks and pleasure grounds where the people may recruit from their labour and the children play in safety.

Infectious Disease.—Local health authorities have been entrusted with important duties in regard to the prevention and control of infectious disease and have developed elaborate machinery for this purpose. The Infectious Diseases Notification Acts of 1889 and 1899 made certain of the commoner infectious diseases notifiable to the Medical Officer of Health and gave local authorities power to add to their number where it seemed necessary and expedient to do so. Since then other diseases have appeared in epidemic form, such as cerebrospinal fever, anterior poliomyelitis (infantile paralysis), encephalitis lethargica (sleepy sickness), and the central department, acting under authority of the Public Health Act 1875, has made these diseases notifiable by regulation and prescribed the measures which should be taken for their prevention and control.

The measures adopted by a local authority to control the spread of an epidemic disease are briefly,—isolation of the patient, either in the home or, where this is not practicable, in hospital, search for the source of infection; observation of the contacts; disinfection; and, where an efficacious vaccine is available, vaccination.

Under the authority either of the Public Health Act 1875 or of the Isolation Hospitals Act 1893, most local authorities have provided hospital accommodation for cases of infectious disease occurring in their districts.

Diphtheria, Tuberculosis, etc.—It is obvious that infectious diseases which are indirectly transmitted through the agency of some medium such as water, milk, food, flies, etc. are more easily prevented than those which are spread directly from person to person, and the measures that are applicable to the one do not always prove successful in the case of the other. For this reason typhoid, cholera, and other intestinal infections which formerly exacted such a heavy toll of life, no longer cause health authorities serious anxiety. In the same category one may place malaria, typhus and other insect-borne diseases. The diseases which are conveyed by personal infection, such as scarlet fever, diphtheria and the various epidemic nervous diseases, are much more difficult to control. The infection of many of these maladies is very widely spread throughout the community and many persons contract the disease in what may be called a sub-clinical form without being conscious of it. The occasional clinical cases are often merely the apex of a considerable pyramid of infection, the greater part of which is submerged and unrecognized. One of the great problems of preventive medicine is to elicit the factors which

determine these periodic clinical or epidemic manifestations of an infectious disease. Various theories have been propounded, but none of them is entirely satisfactory. Other diseases, such as tuberculosis, have a dual character, *i.e.*, they may be transmitted directly from person to person or may be conveyed through the medium of some food such as milk or infected meat. Tuberculosis is a disease of great economic importance because the chief burden of mortality falls on the middle or productive years of life. It is for this reason that special measures have been taken to combat it in the form of notification, dispensaries, sanatoria and the other machinery established under the Tuberculosis Regulations. Somewhat similar measures, suitably modified, have been devised for the prevention and treatment of venereal diseases.

Food Inspection.—The most important measures dealing with food inspection are the various Sale of Food and Drugs Acts 1875–1907, the Public Health (Regulations as to Food) Act 1907 and the Milk and Dairies (Consolidation) Act 1915. Under these powers regulations have been made by the Central Authority dealing with such subjects as milk and cream, meat, shellfish, imported food, preservatives and the prevention of tuberculosis. To a country which imports a large proportion of its meat from abroad it is very important to have some means of supervising production at the source. Agreements have been entered into with the chief producing countries by which these countries undertake to inspect and stamp all meat intended for export to England. This reduces the inspection necessary on arrival. A certain amount of inspection is carried on both at the ports and at the chief distribution centres in order to ensure that the producing country fulfils its undertaking. The results of this method of control have been extremely satisfactory and every opportunity is taken to extend the system.

The local sanitary authority exercises supervision over the quality of the food distributed in its district and the conditions under which it is stored and sold to the public. For this purpose officers are appointed for the inspection of slaughterhouses and dairies, and samples of food are regularly submitted for analysis.

School Medical Service.—The introduction of compulsory education made it apparent that many children were unable, through ill-health, to benefit from the education facilities provided. This led to the establishment of the medical inspection of school children in 1907 and the gradual evolution of the present School Medical Service. The most important statute dealing with this subject is the Education Act of 1921 which re-enacts and amplifies previous powers and imposes on local education authorities the duty of making adequate and suitable arrangements for the medical inspection and treatment of children attending public elementary schools and also the medical inspection of scholars attending secondary schools. Education authorities are also required to make special provision for blind, deaf, defective or epileptic children.

This systematic inspection has revealed a vast amount of unsuspected disease and minor defects which, if left uncorrected, lead in time to serious crippling. It is estimated that out of a total school population of some 7 millions, over a million children require medical treatment, apart from uncleanliness and dental diseases. The seeds of much of this ill-health are sown before the children enter school, a fact which emphasizes the importance of the pre-school welfare work which has already been referred to. On the other hand, the full fruition of school medical inspection can only be assured by continuation of the supervision during the critical transition years of early industrial life. Here the advantages secured by the National Health Insurance Acts of 1911–1924 are becoming apparent. With certain exceptions these provided for compulsory insurance against sickness of all employed persons between the ages of 16 and 70. (For further industrial welfare measures *see* INDUSTRIAL WELFARE AND MEDICINE and LABOUR LAW.)

Port Sanitary Administration.—Port sanitary authorities are constituted by order of the Ministry of Health. They carry out duties imposed by the regulations relating to cholera, plague and yellow fever and other "quarantine" work according to the system of International Sanitary Conventions to which this country is party; the Aliens Order 1920, the Port Sanitary Authorities (Infectious Diseases) Regulations 1920, and the Public Health (Imported Food) Regulations 1925. The sanitary staff of a port sanitary authority consists of the Port Medical Officer of Health and such assistants as the volume of work demands. In recognition of the national importance of this work, half the approved expenditure of a port sanitary authority is defrayed out of Central Governments funds.

International Health.—Many public health problems are international in character and there is evident need for some organization which will enable the nations to pool their experience and, where necessary, to co-operate in the application of such measures as are practicable for the prevention and control of disease. The first attempt to secure international uniformity in matters of quarantine was made in Paris in 1851 when a Convention embodying the precautions against infectious diseases which were then regarded as appropriate was signed by the participating countries. Modifications have been introduced into this Convention from time to time and in the Rome Agreement of 1907 an office or bureau called the International Office of Public Health was established in Paris to consider how best the convention could be amended and kept abreast with medical science. England, by reason of its vast international traffic, has been very directly interested in these conventions and has long been at pains to introduce a spirit of reasonableness into their requirements. The last convention, which was signed in Paris in 1926 by the representatives of 70 different nations, embodies most of the views that have long been held and practised in this country. This convention aims at securing what is necessary for the prevention of the introduction of disease with the minimum of interference to commerce and travel.

In the Peace Covenant a clause was introduced providing for the establishment of a health organisation at Geneva under the aegis of the League of Nations. The functions of this organisation cover practically the whole field of preventive medicine wherever co-operation between the nations is desirable or essential. By arrangements with the international office in Paris it undertakes the collection and dissemination of current information on epidemic disease: it gives assistance in times of national emergency as during the great epidemic of typhus in Russia in 1919, during the epidemic of malaria in Southern Russia, in Greece during the influx of refugees from Asia Minor and other parts of Turkey, and during the recent outbreak of dengue in Athens. It has done much to secure the standardization of various medical preparations, such as insulin, pituitrin and certain of the antitoxins. It has promoted inquiry into cancer, certain aspects of maternity and child welfare and tuberculosis.

Public Health Finance.—The expenses of the public health services are defrayed for the most part out of local rates (general district rate or special rate), but assistance is given by the Central Government in respect of what are known as the "grant aided services." Thus half the approved expenditure on school medical inspection, maternity and child welfare work, tuberculosis and port sanitary services, and three-quarters of the expenditure on venereal diseases is defrayed from funds provided by the Treasury. With the exception of certain of the larger boroughs, half the salaries of the medical officers of health and of the sanitary inspectors is refunded out of Exchequer contribution grant.

The question of the substitution of a block grant covering all health services for these special grants-in-aid is at present under consideration by Parliament. (G. BUC.)

II. THE UNITED STATES

A definition which expresses admirably the social and scientific conception of public health in America is that of Winslow, "Public health is the science and art of preventing disease and promoting physical health and efficiency through organized community efforts for the sanitation of the environment, the control of community infections, the education of the individual in principles of personal hygiene, the organization of medical and nursing services for the early diagnosis and preventive treatment of disease, and the development of social machinery which will ensure to every individual a standard of living adequate for the maintenance of

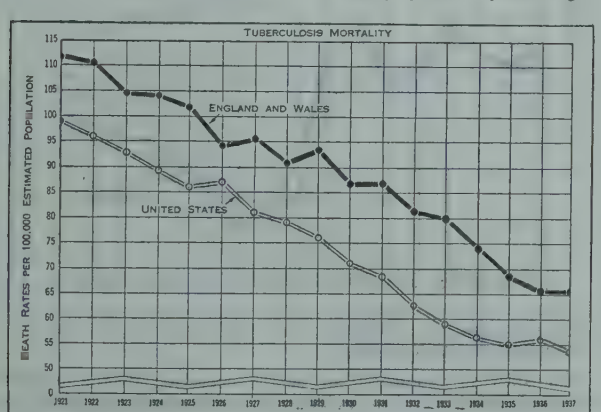
[6]Includes capillary bronchitis.
[7]All forms.
[8]Includes deaths from all causes not otherwise indicated.

health." Progress in public health is shown by the following facts.

Increase in the Average Length of Life.—The health of the people of the United States has been improving consistently for the past 50 years as is revealed by the official morbidity and mortality rates and estimates of life expectancy. Even as late as 1880 the average length of life in the New England States and New York city probably did not exceed 40 years. By the beginning of the present century this had increased to 49 years for the original Registration States and in 1920 to 56 years for at least the 85% of the population in the registration area. Latest studies (1940) show the average duration of life for the white population is beyond 60 years. It is entirely possible, without any additions to the present knowledge of the causes and means of prevention of disease, that an average duration of life of 70 years may be attained by 1970.

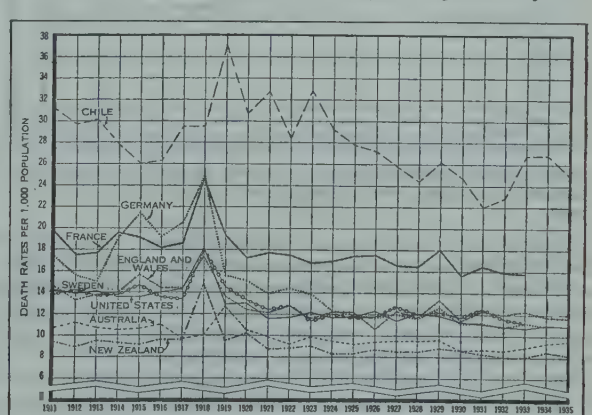


BY COURTESY OF BUREAU OF MEDICAL ECONOMICS OF AMERICAN MEDICAL ASSOCIATION

FROM ANNUAL REPORT, CHIEF MEDICAL OFFICER, MINISTRY OF HEALTH, 1937; BUREAU OF THE CENSUS AND U.S.P.H.S. REPORTS, 1938

Decrease in Death Rate.—In 1870 there were 30 deaths from all causes for each 1,000 of the total population of New York city; in 1937 there were 11·4. Similar changes have occurred in other large cities and in the rural populations, although the city rates were higher in the beginning and have fallen at a more rapid rate than have those of rural communities. In some instances the city rates have been, for recent years, lower than the rural. Since 1900 the general death rate for the registration area of the United States has fallen from 17 to 11·4 per 1,000 of the population.

The past quarter century—1910–35—during which an increasing shift of the population took place from rural to urban residence (55% urban in 1927), was characterized by a greater improvement in general health conditions in both city and rural regions than in any previous similar period of time.



BY COURTESY OF BUREAU OF MEDICAL ECONOMICS OF AMERICAN MEDICAL ASSOCIATION

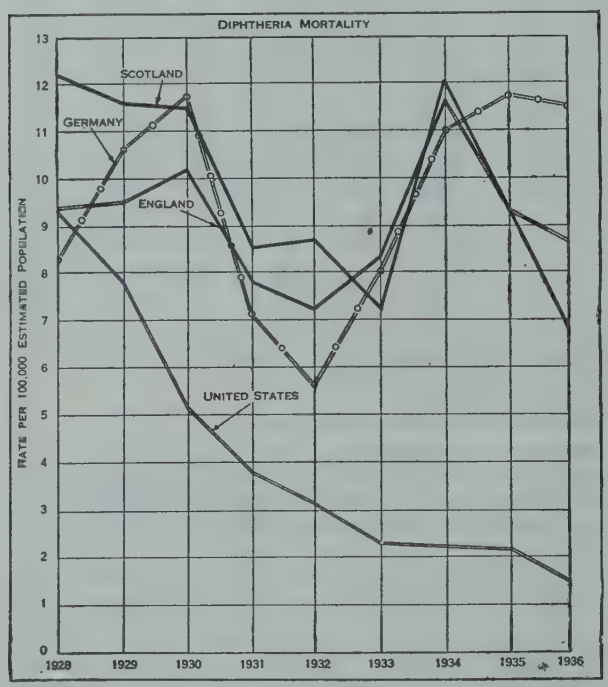
GENERAL DEATH RATES OF THE UNITED STATES REGISTRATION AREA AND CERTAIN FOREIGN COUNTRIES FOR EACH OF THE YEARS FROM 1911 TO 1935—FROM MORTALITY STATISTICS, U.S. BUREAU OF THE CENSUS

The advantage of the rural dweller over the city dweller is found in each decade of life, at least up to the age of 50, and this applies to both sexes.

Changes in Specific Death Rates.—More indicative than are general death rates, of the success of sanitation, personal hygiene and the application of administrative government and social resources for disease prevention, are the changes in the death rates from tuberculosis, typhoid fever, diarrhoea and enteritis among children, diphtheria and the infant mortality. All of these have fallen without exception in those States and cities where reliable records are available.

Typical experience is expressed in the following:

The greatest reduction in the death rate from tuberculosis has been in children under ten. The highest tuberculosis death rates for the country as a whole are those of women from 20 to 30 years of age and for men from 45 to 60.



BY COURTESY OF BUREAU OF MEDICAL ECONOMICS OF AMERICAN MEDICAL ASSOCIATION

FROM ANNUAL EPIDEMIOLOGICAL REPORTS, HEALTH ORGANIZATION, LEAGUE OF NATIONS, 1931-36: SPECIAL ARTICLE, *J.A.M.A.*, JUNE 26, 1937

Typhoid fever, from being an endemic disease of cities, chiefly due to polluted water, is now characterized by its epidemic character resulting from carriers, milk products, oysters and accidental occasional failures of water purification. The endemic typhoid areas are now the small towns and villages of rural States where unprotected water and unpasteurized milk are used.

Diarrhoea and enteritis, from being the leading cause of death in children under five, and particularly among city children and especially in the summer months, now plays a minor rôle, is less prevalent in cities than in rural areas and is hardly more frequent in summer than in winter.

Diphtheria. Now that means of permanent and universal protection of children against diphtheria by active immunization are available, in addition to the resources for specific therapy and determination of susceptibility, the practical disappearance of diphtheria as a frequent cause of death in children under five years of age is within sight.

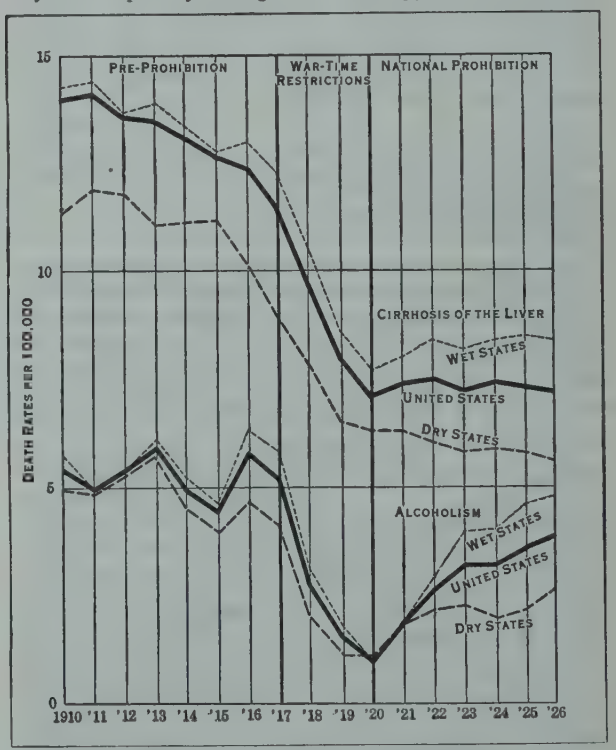
Infant Mortality. While 50 years ago one out of every four babies born alive died within the first year of life, now only one in 20 is so sacrificed. This saving in child life has occurred wherever education of the mother has been provided by doctors and nurses, and water and milk supplies have been safeguarded. It is common to find infant mortality rates lower in the cities than in rural communities, a reversal of the conditions 50 or even 25 years ago.

Increasing Death Rates.—The saving of life in the early years of childhood, particularly from diseases peculiar to infancy and from communicable diseases affecting chiefly children under five, and from tuberculosis in persons from 15 to 30 years of age, since about 1900, has, together with the limitation of immigration altered the age composition of the population to a degree affecting the rates from such causes of death as affect persons over 45 years of age. Of these the most important are heart diseases, cancer and diabetes.

The increases in the death rates from heart diseases, cancer and diabetes are in part due to the higher age grouping of the population as a whole, but in addition to this, the death rates for each decade over 45 show increases for each of these diseases.

Deaths from violence and accidents, particularly those due to automobiles, and from appendicitis have increased sharply in recent years. Deaths from causes connected with childbirth have not declined greatly, and those in the United States are above those of other countries with reliable records.

While in 1866 in New York city one death out of every 2,400 was due to diabetes, now (1940) one in 40 is from this cause. The increase, while greater in the cities, is found also in rural populations and among the coloured as among the white races, but everywhere especially among women over 35 years of age.



MORTALITY DUE TO ALCOHOLISM AND CIRRHOSIS OF THE LIVER IN THE UNITED STATES (1910-1926)

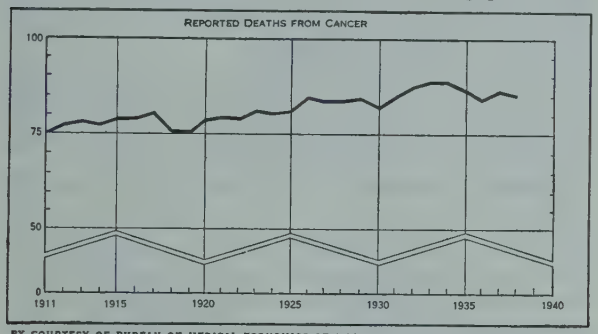
The shift in proportion of deaths occurring in the various decades of life is a striking evidence of the effective control of the communicable diseases of childhood and early maturity.

Drop in the Birth Rate.—With the reduction in loss of infant life has come a lowering of the birth rate in the United States as a whole and for each State and racial group. Within the past 50 years the birth rate has dropped from approximately 40 per 1,000 population per annum to 16·7. From 1921–25 the birth rate was 22·5 in the birth registration area and in 1936 it was 16·7.

The Three Eras of Public Health.—For the first 125 years of the life of the nation, public health work was limited to control or improvement of man's physical environment and enforcement of quarantine by the exercise of the authority of the official health agencies, the boards and departments of health acting

under the police powers which are reserved to the States under the federal constitution. This may be called the era of sanitation, the great accomplishment of which was the reduction of communicable diseases transmitted largely, if not exclusively, through drinking water polluted by human wastes. Sanitary disposal of sewage, the protection and purification of water supplies, the control of nuisances and the improvement of housing constituted the first effective attack on environmental hygiene and saved the cities from destruction. At the beginning of this era death rates in the large cities equalled or exceeded the birth rates. The health officer relied upon legal rather than scientific authority, upon the force of police powers rather than the power of education and authority, upon his individual or departmental services rather than upon the technical assistance and popular influence of volunteer co-operating agencies and associate professional groups.

Not until Lemuel Shattuck in Massachusetts in 1848 and Dr. Stephen Smith and his associates in New York city in 1865 had disclosed by careful surveys of the health of the population the



BY COURTESY OF BUREAU OF MEDICAL ECONOMICS OF AMERICAN MEDICAL ASSOCIATION

STANDARDIZED DEATH RATE PER 100,000 INDUSTRIAL POLICY-HOLDERS, AGES 1-74 YEARS. THE 1938 RATE IS PROVISIONAL.—SOURCE: "TWENTY-FIVE YEARS OF LIFE CONSERVATION," AND STATISTICAL BULLETINS, METROPOLITAN LIFE INSURANCE COMPANY

true extent of preventable disease and death, and the fact that the death rates in the cities were higher than the birth rates did the public demand something approaching qualified direction and consistent scientific operation of a well-organized department of health. The first State department of health was organized in Louisiana in 1853.

In 1900 there began the movement for public education in health which has been a factor of tremendous importance ever since, not only in the widespread dissemination of popular information about preventable disease, but in bringing to the support of the official health department or health officer interest, knowledge, financial assistance and public opinion through the influence of volunteer or unofficial health agencies.

The initial movement of this educational or public informational era of public health was that of the tuberculosis committees and societies and national, State, and local associations, now operating with undiminished vigour and sustained interest and financial strength as the National Tuberculosis Association. The three simple facts with which the public was approached were the communicability, curability and preventability of tuberculosis. Once accepted, it was inevitable that knowledge of these facts should lead to appropriate communal action. The National Tuberculosis Association, its 48 State societies and 1,300 other local societies have been the exciting, if not the driving, force which has brought 600 tuberculosis clinics, 60,000 sanatorium beds for tuberculous patients (1922), a tuberculosis division in all important State and local health departments and a scientific program of prevention uniformly accepted as an essential part of the work of the public health officer and department of every community.

The most important features of the program of the National, State and local tuberculosis associations since the beginning of the movement in 1904, have been those measures which have brought about "notification and supervision of persons afflicted with tuberculosis; the construction and maintenance by cities, counties and States, of institutions for the care and treatment of tuberculous patients of all types; institutions for the prevention of tuberculosis, such as preventoria, open-air schools and camps; the instruction of the public in the methods of avoiding and curing tuberculosis; and finally the intensive scientific study of methods to be used in the prevention and treatment of tuberculosis."

Following the leadership and example of the tuberculosis associations, there were developed similar private health agencies first as local societies and later on a national scale to carry a lesson of prevention and of health on the subject of infant mortality and child hygiene, on pre-natal care of the expectant mother, on social hygiene, a synonym in the United States for venereal disease control, on mental hygiene, cancer, blindness, heart diseases, etc., until the country was swept with successive waves of specialist health propaganda to stimulate appropriate public and official action. It is not unusual to find that twice as much money is spent for public health through the private agencies as is invested by the taxpayers in their official health department.

The third era of public health which was just emerging in 1928 as a definite new phase, out of that of public information or health education, had its inception in the World War experience from which the conviction developed that only by the systematic use of the periodic health examination could all the potential benefits of preventive medicine be made effective for the individual.

With the common action of the American Medical Association and the unofficial and official health agencies through the National Health Council in 1922 an agreement was reached which has been followed with much success. The objective of the present era of public health is to obtain from the prenatal stage until old age for each individual the benefits of personal medical guidance in a healthy way of life, in addition to medical services for the care of sickness. The supervision of the expectant mother, the guidance of the infant's growth, the supervision of the development of the runabout child of two to five, the protection of the health of young people and adults of middle age until their years of work are over in old age all depend for their effectiveness upon individual application of the principles of personal hygiene according to the requirements of age, sex, work, personality and the limitations of inheritance and of economic and social status.

The policy has been to inform the public through official and volunteer health agencies of the benefits to be obtained from a periodic medical examination and to train physicians to carry out the technical service required. Personal interest in and responsibility for individual health is essential if the present knowledge is to be effectively applied through the mechanism of medical examinations and health conferences.

In all health matters pertaining to interstate and foreign commerce the responsibility rests with the Federal Government through the U.S. Public Health Service of the Federal Security agency. In addition to large functions in medical relief, particularly for merchant seamen, the Public Health Service maintains active consulting and co-operative relations with State and local health authorities, carries on widespread attack upon the venereal diseases through a variety of channels, supervises and controls the standards and production of biological products used for diagnosis and treatment of disease, maintains an effective information and education service of national scope, and carries on researches in sanitation, preventable diseases and vital statistics.

Health activities of various kinds are carried out under six other Cabinet departments and many more independent establishments of the executive branch of the Government.

Local health organizations may not set up standards or enforce local ordinances inconsistent with those established by the competent State authority.

Not only cities, towns and incorporated villages, but counties and rural districts to an increasing degree maintain self-contained health departments adequately performing the essential functions.

A minimum provision for any unit of population of 50,000

persons or over as conceived by the professional public health workers of the United States is as follows: a full-time health officer, qualified by training and experience, free from partisan political interference in tenure of office, and paid a salary in proportion to the responsibility of the position; a board of health or advisory health council; trained personnel, including public health nurses to the number of one to every 3,000 of the population, capable of carrying on the seven functions previously described, and a budget based upon an appropriation from public funds of $1.00 to $2.00 per capita for health purposes.

Adequate provision for the organized care of sickness in any community of 50,000 persons or more includes at least:

A general hospital with a capacity of five beds for each 1,000 of the population for the use of general medical and surgical patients, and for maternity cases, and space for the cubicle isolation of acute communicable diseases (one bed for each 2,000 of the population). Beds for diagnosis and observation of tuberculosis, venereal disease and mental patients should be included.

A tuberculosis sanatorium with accommodations for one patient for every 1,000 of the population.

Hospital facilities for three mental patients for each 1,000 of the population. Institutional provision for chronic invalids and convalescent patients according to the social, economic and industrial status of the people.

While all local health departments do not have direct responsibility for the care of the indigent and other sick of the community, the hospital care of the acute communicable diseases and often of tuberculosis and venereal diseases is commonly under the health officer.

Interest in treatment and prevention of all sickness is within the proper province of the health officer and unless the institutional and private physician facilities for the diagnosis and care of sickness are adequate, a community cannot have a wholly satisfactory service for health.

ORGANIZED HEALTH WORK

In the United States the problem of the proper or desirable division of public health authority between Federal, State, and local agencies is one as yet unsettled. By the Federal Constitution, the State is the ultimate authority and each State jealously guards its autonomy in matters pertaining to public health.

In the same way the local authorities demand ultimate power in relationship to certain health functions which relate wholly to the health problems of the local community. The development of many nongovernmental health agencies is also to be considered in the evaluation of public health work in the United States.

The chief questions of recent years have related to the inequality of the distribution of the benefits of modern public health and medical science. Thus recent years have seen the conduct of a National Health Survey to determine the amount of chronic disabling illness and the extent of medical service available for its care. Innumerable surveys have also been made of local, State, and national health services. As a result there has been proposed a National Health program, involving the appropriation of vast funds to be distributed to the individual States as grants-in-aid for specific health purposes. Moreover, under the Social Security Act of 1934 extensive funds have been appropriated to the United States Public Health Service and the Bureau of Maternal and Child Welfare in the Department of Labor to carry on extensive preventive, medical, and educational services in the individual States. Under this system, the States must match the appropriation of the national Government and must submit plans for the approval of national bureaus before grants are made.

There is also widespread agitation for compulsory sickness insurance in some of the individual States and by certain agencies which would ask the Federal Government to provide funds for establishing such systems in the individual States. (*See* also HEALTH VISITOR.)

PUBLIC HOUSE, in its general English acceptation, a house in respect of which a licence has been obtained for the consumption of intoxicating liquors. Public houses are frequently distinguished as "tied" and "free." A tied house is one rented from a person or firm from whom the tenant is compelled to purchase liquors or other commodities to be consumed therein. A free house has no such covenant. (*See* LIQUOR LAWS AND LIQUOR CONTROL; TEMPERANCE; PROHIBITION.)

PUBLIC OPINION SURVEYS. The public opinion survey, based on sampling a representative cross-section of the population, was first established as a periodical service in the United States in 1935. The antecedents of the representative sample survey were the market survey and the straw poll.

History.—The *market survey* was originated in 1912 by Roy O. Eastman, then advertising manager for a manufacturer of breakfast food, to determine the readership of various magazines in which his advertisements appeared. In 1919 Eastman set up the first survey department within an advertising agency, and in the same year Percival White established an independent surveying organization, serving agencies and advertisers. From that time on the practice of market surveying, with a crew of interviewers calling on consumers to ask a series of questions about their use of the advertiser's product, spread rapidly through the advertising world. One of the principal practitioners was the J. Walter Thompson Co., an advertising agency with offices in many parts of the world. In nearly all of these places surveys were conducted from 1922 on. The market survey usually was restricted to facts about the uses of products, and paid only incidental attention to opinion. Moreover, the market survey seldom attempted to report on a full cross-section of the population, but confined itself to those who were the most likely market.

The *straw poll* began as an intermittent practice of U.S. journalism in 1824. In that year the *Harrisburg Pennsylvanian* sent out reporters to inquire among the citizens of Wilmington, Del. whether they were going to vote for Henry Clay, Andrew Jackson, John Quincy Adams or William H. Crawford for president. Similar polls were conducted in 1883 by the *Boston Globe;* in 1904 by the *New York Herald;* in 1908, 1912, 1916 by the *New York Herald* in collaboration with the *Cincinnati Enquirer,* the *Chicago Record-Herald,* the *St. Louis Republic* and others; in 1916, 1924 and 1928 by the Hearst newspapers. The most celebrated of the straw polls was that conducted by the *Literary Digest* between 1916 and 1936, after which time it was discontinued because its results compared unfavourably with those of the newer representative sample surveys. The *Literary Digest* straw polls consisted of large numbers of ballots mailed to voters in all parts of the U.S. In a single poll as many as 20,000,000 ballots were mailed, and 3,000,000 were returned filled out by the recipients. The average state-by-state error of the *Digest* polls in predicting election results in 1924 and 1928 was 12% of the plurality forecast, and the extreme error was 39%. The straw polls were unreliable because they did not secure a true cross-section of the voting population. The failure arose from two causes: (1) available mailing lists represented chiefly the upper income strata of the voting population—automobile owners, telephone subscribers, etc.; (2) returned ballots came in larger proportions from those in the upper economic and educational levels of the lists used. These two factors compounded to make the straw poll results a reflec-

tion of the upper income and educational groups. Straw polls were used mainly to forecast election results, but in 1922, 1930 and again in 1932 the *Digest* asked questions about the law prohibiting the sale of alcoholic beverages, and in 1922 questions about granting a bonus to veterans of World War I.

The *representative sample survey* of public opinion was first presented in the July 1935 issue of the magazine *Fortune*. The editors reported and discussed a survey made for them by the market research firm of Cherington, Roper & Wood. Later the successor firm of Elmo Roper, conducting periodical surveys under the editorial direction of *Fortune*, charted large areas of U.S. opinion and recorded major changes in the U.S. view of the world and of governmental policies. In Oct. 1935, Dr. George Gallup, as director of the American Institute of Public Opinion, released a public opinion survey to a group of Sunday newspapers. Subsequently he released the findings of the institute's interviewers, first weekly and later several times a week, to a list of daily and Sunday newspapers throughout the U.S. Similar institutes were started in other countries, usually with Dr. Gallup's advice.

In 1937 a somewhat different type of organization, using questionnaire surveys as well as other surveying methods, was set up in Great Britain by Tom Harrisson and Charles Madge under the title of *Mass Observation*. Starting in 1943, a number of regional surveys were set up within the U.S. Even earlier, regular surveys of certain "interest groups"—farmers, housewives, students, etc.—were established by publishers serving those groups. The principal opinion surveys regularly publishing in 1945 were as follows:

Year Founded	Name	Principals and Home Offices
	National Surveys	
1935	*Fortune* Survey of Public Opinion	*Fortune*, New York, and Elmo Roper, New York, N.Y., U.S.A.
1935	American Institute of Public Opinion	Dr. George Gallup, Princeton, N.J., U.S.A.
1936	British Institute of Public Opinion	*News Chronicle*, London, England, Dr. Henry Durant, director
1937	Mass Observation	Advertising Service Guild, London, England
1939	Twohey Analysis of Newspaper Opinion*	James S. Twohey Associates, Washington, D.C., U.S.A.
1939	Institut français d'opinion publique	*Liberation*, Paris, France
1941	National Opinion Research Center	Marshall Field Foundation, Inc., in association with the University of Denver, Denver, Colo., U.S.A.
1941	Canadian Institute of Public Opinion	Toronto, Canada, Wilfrid Sanders, director
1941	Australian Public Opinion Polls	Melbourne, Australia, Roy Morgan, director
1942	Svenska Gallup Institutet	Stockholm, Sweden, Sven O. Blomquist and Tord Palender, dir.
1942	Instituto Científico de la Opinion Publica Mexicana	Dr. Laszlo Radvanyi, Mexico City, Mexico
1945	Danish Gallup Institut	Wahl Asmussen, Copenhagen, Denmark
1945	Suomen Gallup Oy	Artturi Raula, Helsinki, Finland
	Regional Surveys	
1943	Iowa Poll	*Des Moines Register & Tribune*, Des Moines, Iowa, U.S.A.
1944	Minnesota Poll	*Minneapolis Star Journal & Tribune*, Minneapolis, Minn., U.S.A.
1944	The Bulletin Poll	*The Evening Bulletin*, Philadelphia, Pa., U.S.A.
	Interest Group Surveys	
1935	The Companion Poll	*Woman's Home Companion*, New York, N.Y., U.S.A.
1938	The Farmer Speaks	*Successful Farming*, Des Moines, Iowa, U.S.A.
1938	Wallace-Homestead Poll	*Wallace's Farmer and Iowa Homestead*, Des Moines, Iowa, U.S.A.
1940	*Fortune* Forum of Executive Opinion	*Fortune*, New York, N.Y., U.S.A.
1943	Institute of Student Opinion	*Scholastic Magazines*, New York, N.Y., U.S.A.
1943	Wage Earner Forum	Macfadden Publications, Inc., New York, N.Y., U.S.A.

*Not a "poll"—*see* description under Press and Radio Analysis below.

METHODS OF SURVEYING PUBLIC OPINION

Sampling.—Except in those rare instances when all or substantially all of the people whose opinions are sought can readily be reached, opinion surveys of all types depend upon a sampling of the group being examined. The effort in sampling is to select people from the group in such a way that the completed sample will be in all significant respects a small scale model of the population it is designed to represent. If men and women occur in equal numbers in the population, then men and women are represented in equal numbers in the sample. If a third of the population are 50 years of age or older, then a third of those in the sample will be selected because they are 50 or older. If 5% of a certain population live in a certain city, then 5% of the sample will be drawn from that city. This principle of correspondence of sample to the population is usually applied in national samples to the following categories: sex, age, geographical region, community size, socio-economic level. Refinements and extensions of these controls are often used, and in special samples, where less than a national total is sought, special controls are also needed. For instance, a proper sample of wage earners would have to parallel the actual distribution of wage earners by types of industry. Samples on which reports are published customarily range in size from 500 to 5,000 cases, the most common number for a national sample being 3,000. A margin of 3% is normally allowed in such a sample to cover both statistical and sampling error.

Questionnaires.—The commonest type of public opinion survey relies on a fixed questionnaire uniformly administered to all members of the sample. The character and wording of the questionnaire has much to do with the impression gained from the final results and is a far greater factor in over-all accuracy than are the more easily adjusted statistical controls of the sample. The problems of questionnaire wording and interpretation have to do with the meaning of words and the prevalence of the concepts conveyed, and so cannot be dealt with adequately here. But certain common question forms are worth noting. They are:

1. the direct question, calling for a yes-or-no or no-opinion answer;
2. the multiple choice or list question, calling for the choice of one or more items in a list presented;
3. the open question, calling for a wide variety of volunteered answers which are recorded as given and later classified;
4. the attitude scale, usually calling for response to one of five verbalized attitudes offered on a given subject, the attitudes arranged to reflect unqualified approval, qualified approval, neutral feeling, qualified disapproval, unqualified disapproval (the neutral position is sometimes omitted);
5. the loaded question, which tends to force a certain kind of answer and which, therefore, often reveals the degree of uncertainty of the public when its answers are compared with those to a similar question loaded in a contrary sense;
6. the information question, usually of the direct or list types, but revealing knowledge or ignorance rather than opinion, and of use in opinion work chiefly for its correlation with expressed opinion.

Interviews and Mail Ballots.—Questionnaires are administered either by interviewers calling upon people at their homes or places of business or by mailing to selected lists. Mailing does not produce satisfactory results from a national cross-section for the reasons given above in the discussion of straw polls. But mail ballots sent to lists of fairly homogeneous people often produce results of a reliability higher than that achieved with interviewers. Within a homogeneous group the sampling error is minimal—*i.e.*, those who return ballots do not differ significantly from those who do not. But a person filling out a questionnaire by himself seems to be more likely to tell the truth on matters that affect his social prestige than is a person faced by an interviewer.

Observation.—The questionnaire supplies a uniform stimulus to call forth a varying response from a sample of the public. But public opinion is formed in actuality not so much by questions and answers as by a process of reading, listening, reflection, and spontaneous discussion. Therefore, if the things people choose to read and listen to, and the things people choose to discuss among themselves can be properly observed and intelligibly recorded, another approach can be made to public opinion.

Mass observation, as applied by the British organization already referred to, attempts the approach to spontaneous discus-

sion. The method is to have a large number of observers note in diaries what has been said in their hearing on topics of national interest. The diaries are periodically turned in and summarized. The method leaves much to be desired in exactness and runs many risks of subjective interpretation, but often succeeds in conveying the "feel" of opinion far better than a questionnaire can. The method is also used with more exactness in the observation of public behaviour as an index to public opinion. It was noted, for instance, that there was a close correlation between war news and the number of people carrying gas masks on the streets of London in 1939, 1940 and 1941. When the news was bad the proportion carrying gas masks went up, until by 1941 the news stimulus had apparently worn out. Similarly in the U.S. a correlation was noted in 1944 between the war news and the numbers volunteering as blood donors. When the news was good the number of volunteers dropped off.

Press and Radio Analysis does not report public opinion directly, but, by discovering what people read and listen to and what topics editors bring up, it throws a great deal of light on public opinion formation and change, as well as upon the operations of propagandists (*see* PROPAGANDA). Much of the early work in press analysis was done by Harold Lasswell, formerly associate professor of political science at the University of Chicago, from 1927 on. The first of the regular surveys of editorial opinion was published by James S. Twohey for a limited list of subscribers in business and government offices. The first press analysis prepared for a general readership was published in *Fortune* for Sept. 1944, and reported on the content of 50 labour papers taken as a sample of the some 928 labour papers published in the U.S. The radio popularity ratings published by Archibald Crossley after 1930 gave the approximate audiences of the news commentators and hence furnished a clue to the popularity of certain opinions. The Office of Radio Research under Dr. Paul Lazarsfeld at Columbia university, by itself and also in collaboration with Dr. Frank Stanton of the Columbia Broadcasting System, published a number of studies of radio coverage and of the reactions of listeners to programs.

FINDINGS OF SURVEYS

Elections.—The most publicized, though probably the least useful, of all the findings made through public opinion surveying is the election forecast. It is undertaken by serious surveyors of opinion because it provides dramatic validation for a method that can be of general public service only if it is widely accepted as valid. The record in U.S. national elections is as follows:

Error in Predicted Majority in Percentage Points

	American Institute of Public Opinion (Gallup) *less than*	*Fortune* Survey of Public Opinion (Roper) *less than*	Crossley *less than*
1936	7	1	7
1940	3	1	—
1944	2	1	2

In all, the American Institute through 1944 predicted 116 national, state and local elections with an average error of less than 3%.

Political Opinion.—The chief use to which public opinion surveying had been put in the U.S. regularly by 1945 was the reporting of popular sentiment on the large questions of policy currently before the people. Opinions were sought on U.S. entry into war, on drafting men for the army and for work, on peace terms, on tariffs, on taxes and on most of the matters that make up the agenda of a government. In Great Britain in 1934–35 surveying was put to a dramatic use when the opinions of 12,000,000 people were recorded on the League of Nations, with especial reference to armaments and the application of sanctions to aggressors. This survey was an unofficial plebiscite rather than a sample survey, but its very scope gave weight to the finding that a clear majority of the people of Great Britain favoured a rigorous application of sanctions. In the U.S., surveys traced the path of thought that the people followed between 1939 and 1941 in making up their minds about U.S. participation in World War II. In 1944 and 1945 surveys in various countries allied against the axis powers followed sentiment concerning treatment of the enemy.

Civic and Social Problems.—In addition to their use on matters of current national policy, surveys have been widely used to determine general public or special group attitudes toward proposals and practices in the fields of education, medicine, race relations and labour relations. Surveying on a local scale has been useful in getting the views of the community on such purely local concerns as street repairs, street lighting, water supply and curfew regulations. Contributions have been made to public health work by surveys reporting the incidence of common colds throughout the population at certain times.

Administrative Uses.—After 1939, increasing use of public opinion surveys was made by administrators in government and in business both in Great Britain and the U.S. Surveys in Great Britain provided clear clues to the effectiveness or ineffectiveness of various domestic propaganda drives sponsored by the government. Surveys conducted by the U.S. army gave valuable information on morale of the troops and on demobilization plans. Surveys of a variety of types were used to check on the rationing and price control programs. Large corporations "affected with a public interest," began to make regular checks of public attitudes toward them.

RECORDS

Published Material.—Little of the public opinion material gathered for journalistic use was available in book form in 1945, but nearly all of it was accessible in some form. The *Public Opinion Quarterly* carried and indexed summaries of Gallup findings from 1935 on; of *Fortune* findings from Sept. 1939 on and added certain other surveys afterward. At Princeton university, the Office of Public Opinion Research, directed by Dr. Hadley Cantril, filed the tabulating cards of its own and of the U.S. and British Gallup surveys. At Denver university, the National Opinion Research Center, directed by Dr. Harry Field, began publishing in Sept. 1943 a fortnightly summary of outstanding surveys in the U.S. and abroad. After 1943 *Fortune* maintained a file of all published surveys, indexed by subject. At all three of these centres the archives were opened to qualified inquirers.

Unpublished Material.—The great bulk of public opinion surveying done for administrative purposes has remained unpublished and inaccessible. Much of the governmental material has been marked for release at some later date. A small part of the corporation material has been similarly marked.

BIBLIOGRAPHY.—Hadley Cantril and research associates in the Office of Public Opinion Research, *Gauging Public Opinion* (1944); Paul F. Lazarsfeld, *The People's Choice* (1945); William A. Lydgate, *What America Thinks* (1944). (R. WD.)

PUBLIC RELATIONS, the activities connected with interpreting and improving the relationships of an organization or an individual with the public. The persons in charge of these activities are usually known as public relations directors, public relations consultants, etc.

Professional associations in the public relations field have maintained that the use of titles of this kind is justified only in the case of those who operate on a policy-making level, so that they have a voice not only in securing publicity for the activities of their employers, but also in making those activities conform to the public interest. However, the term has been widely used by publicity men without regard to this distinction.

The first industries to make general use of the term public relations were U.S. railways and public utilities. For example, the *Electric Railway Journal* for Dec. 13, 1913, said in an editorial that "the subject of the public relations of public utility companies occupied almost exclusively the attention of three important conferences this week in New York." Earlier uses of the term include an address by Dorman B. Eaton on "The Public Relations and Duties of the Legal Profession" to the graduating class of the Yale Law school in 1882. Thomas Jefferson used the term in his address to the 10th congress in 1807, but in the sense of foreign relations.

Forerunners of Public Relations.—While the term public relations did not come into general use until after World War I, many of its basic activities are as old as history. Primitive priests and medicine men performed public relations functions on behalf of their tribes when, in order to eliminate customs that were found to endanger the health or safety of the tribe, they built bodies of legend to give sanctions to their prohibitions.

In the 5th century B.C., the Greek poet Simonides put his muse at the service of publicity, selling songs of praise. This practice seems to have been generally considered in bad taste. However, even the fastidious Pindar accepted money from those he glorified in his odes. Among his patrons were the great merchant princes of Aegina. Plato in his *Republic* attacked poets as special pleaders, and advocated the suppression of all except those hired by the state to serve its welfare.

The Rosetta stone is an example of the governmental public relations work of the priests of ancient Egypt. The inscription, made in accordance with a decree passed by a general synod of priests in 196 B.C., informs the reader that the boy king Ptolemy V has been generous and just, and his policies conducive to prosperity.

In 60 B.C., shortly after he had become consul, Julius Caesar decreed that the acts of the Roman senate should be publicized. A bulletin, the *Acta Diurna,* was posted, and also issued in manuscript form. This publication announced that Caesar had been

offered the crown, and had refused it.

Augustus Caesar, foreshadowing a feature of Benito Mussolini's policy, ordered publicity given in the *Acta Diurna* to citizens who were rearing large families.

Gaius Maecenas, friend and adviser of Augustus, helped direct the genius of Virgil and Horace into channels that greatly enhanced the public prestige of the emperor. John Buchan, in his biography *Augustus* (Houghton Mifflin Co., 1937), sums up the role of Maecenas: "It was his task to feel the pulse of public opinion and to advise the blunter intelligence of the Princeps, and not less to create opinion for his day and for all time."

Under the influence of his friend and patron Maecenas, Horace portrayed Augustus as a symbol of enlightenment and peace. Similarly, Virgil in the *Aeneid* bolstered the pride of citizens by telling that the greatness of Rome had been foretold from the earliest days. In this feat of retroactive prophesy, he included the statement that Rome's ultimate grandeur was to be achieved by the men of the Julian house—the family of Augustus.

In the dark ages, wandering minstrels were made welcome at great castles largely because of the influence on public opinion they were able to exert on behalf of their patrons. The Anglo-Saxon scop or bard had become a respected personage by the 5th century.

The mediaeval guilds performed a public relations function for their members by maintaining the standards and dignity of their crafts. However, in contrast to modern trade associations, which publicize their methods, the guilds emphasized the "mysteries" of their vocations. Thus business became wrapped in a tradition of secrecy which tended to leave it defenseless against its critics.

A powerful handicap to the mediaeval businessman was the doctrine of St. John Chrysostom that "whoever buys a thing in order to make a profit selling it, whole and unchanged, is the trader who is cast out of God's temple." St. Thomas Aquinas amended this doctrine to permit a profit, but at a "just price" which involved a small margin.

In Augsburg, Ger., the house of Fugger, extending its banking and trading interests internationally on a large scale in the early 16th century, was hampered by restrictive laws and adverse public opinion. Jakob Fugger took his problem to Konrad Peutinger, a humanist scholar and an adviser to Emperor Charles V. Peutinger, a great forerunner of the modern public relations man, wrote a series of essays on the moral and legal aspects of trade. He pointed out that merchants were frequently forced to sell their goods at a loss, and maintained that accordingly every trader should be free to get as high a price for his wares as they could command. He argued also against restrictions on monopolies and cartels. Largely because of Peutinger's activities, the Augsburg council voted to do away with restraints on business.

In England, up to the middle of the 18th century, when it became possible for writers to look to the public for their livelihood, it was not unusual for authors who lacked private patrons to be in the pay of political groups. Swift put his talent at the disposal of the Tories, Prior and Addison of the Whigs. From 1731 to 1741, Walpole used nearly £50,000 of secret service funds for the pay of writers and printers.

In France, Racine and Molière were among the distinguished writers who supplemented their incomes by writing eulogies of royalty.

Napoleon Bonaparte made adroit use of opinion-moulding techniques throughout his career. In 1793, when there was a general revolt by Southern federalists or counter-revolutionaries against the new constitution, Napoleon's regiment was among the units engaged in suppressing the uprising. Sent on a mission to Beaucaire, he wrote a pamphlet, *Souper de Beaucaire,* to prove that the rigours of the revolutionary government were mild compared to the vengeance that the *ancien régime* would exact if disunion opened the way for its return. The pamphlet brought the young officer to the approving notice of the Convention.

In 1796, placed in charge of the army of Italy, Napoleon drafted a proclamation to his unpaid, badly equipped soldiers that gave a dramatic lift to their morale. William Milligan Sloane, in *The Life of Napoleon Bonaparte,* says of the French entry into Milan: "No scene in the history of warfare was more theatrical. The pageant was arranged on the lines of a Roman triumph, and the distances so calculated that Bonaparte was the one impressive figure." [1]

Having used pomp as an effective publicity instrument, Napoleon now showed that he could do likewise with simplicity. On his return to France he dressed plainly, visited minor officials who would normally have been expected to make the overtures—and saw to it that the modesty of his conduct was reported in the official journal, *Le Moniteur universel.*

In colonial America the talent of Samuel Adams for wooing public opinion proved a great asset to the Revolutionary cause. Typical of his practical approach to such questions is the letter he drafted for the Committee of Correspondence on Dec. 16, 1773. "We inform you in great haste that every chest of tea on board the three ships in this town was destroyed the last evening," the letter begins, and continues: "without the least injury to the vessels or any other property."

Developments in 19th and 20th Centuries.—In the early 19th century, U.S. newspapers frequently granted the hospitality of their news columns to publicity stories in return for paid advertisements. Other papers, inadequately staffed, accepted contributions without too close a scrutiny as to the motives of the writers. Shortly after the Civil War, land promoters, railroads, politicians and financial groups were making systematic use of such opportunities.

In 1869 James McHenry, press representative of the Fisk-Gould financial group, obtained wide publication of material in their interest. Shortly after this, a number of business and political organizations installed publicity departments, under the name of "literary bureaus."

Promotion-minded businessmen realized that it was possible to create news events that the newspapers would report as a matter of course. An outstanding instance of this occurred in 1892 when the manufacturers of "Sapolio" sent a 14-ft. sloop to Spain to participate in the 4th centennial of Columbus' voyage to America.

The technique of creating news events had already been brought to England by Thomas J. Lipton, who in 1881 arranged to have the world's biggest cheese manufactured in the United States, and created an effective fanfare of publicity when it reached his main store in Glasgow, Scot.

In the last decade of the 19th century and the first of the 20th, publicity men were multiplying in New York city. Almost all of them were former newspaper reporters. Knowing the ingredients of a lively newspaper story, some of them—particularly theatrical press agents—drew freely on their imaginations.

In 1909 the American Newspaper Publishers association, alarmed at the spread of press agentry, appointed a Committee on Free Publicity. One bulletin issued by it listed 757 "space grabbers."

However, most newspapers continued to use a substantial amount of material from publicity sources. A parallel situation occurred later in Britain. *Report on the British Press,* published by Political and Economic Planning in 1938, stated: "Some newspapers are very much opposed to accepting material from press agencies, and not long ago the Home and Southern Counties Newspaper Federation, representing nearly 300 newspapers, made a concerted attempt to eliminate it. Nevertheless, many of these newspapers continued to print such material, the news-value in them proving too strong a bait."

In both instances the attempted boycotts resulted in a more objective attitude toward publicity. In an article entitled "The Press Agent, His Rise and Decline," published in *Collier's* in 1911 (Crowell-Collier Publishing Co., New York, N.Y.), Will Irwin said: "No more may such as Channing Pollock trick the newspapers by having a popular actress develop a case of aphasia on the steps of the Eden Musee; no more may Toxen Worm draw column after column of space by strewing tanbark before the theatre to 'save the nerves' of an overstrung English star."

Irwin's epitaph for trickery was premature; many years later some of the old press agent devices were still in use, together with

[1] From *The Life of Napoleon Bonaparte,* vol. 1. Copyright, 1939, D. Appleton-Century Company, Inc. Reprinted by permission of Appleton-Century-Crofts, Inc.

such new ones as obtaining mention of clients in syndicated columns by attributing to them witty remarks invented or borrowed for the occasion. However, the article included a defense of the better type of press agent that might well stand as a vindication of his successor, the public relations man:

"A press agent, a special pleader it is true, but perhaps a fair one, helps wonderfully to mutual understanding. . . . The corporation head, associating only with his kind, may be as foolish as any man in misunderstanding the public. The press agent is always a graduate newspaperman. As such, he is an expert on public opinion. He can counsel against these unsympathetic follies; and often he does."

Leaders of business and finance had already begun to think along these lines. Until recently they had been opposed to any publicity except commercial puffs, and had strongly rebuffed newspapermen. The prominent banker George F. Baker told a reporter: "It's none of the public's business what I do." J. P. Morgan said to another "I owe the public nothing." William H. Vanderbilt, when pressed for a statement about reduction of train schedules on his railroad by a reporter who talked insistently of the public interest, exclaimed: "The public be damned!" Associated Press editor Melville E. Stone said in his memoirs that Vanderbilt's ire had been directed at the reporter rather than the public. However, great damage had been done.

The businessman's belief in his right to secrecy was an honest one, rooted in a tradition dating back to the mediaeval guilds. But it was dangerous to rest on real or supposed rights, in view of popular antagonism toward big business. This attitude was equally traditional; in fact, one of the motivations of the Boston Tea Party had been the fear that the British East India company would crush small merchants by selling directly to consumers.

A clash between the two traditions was forestalled for a long time by the availability of homestead lands in the west, which tended to mitigate causes of discontent. The drying up of this source of opportunity was accompanied by an epidemic of attacks on big business.

In 1886 there was a series of strikes, some marked by violence. Edward Bellamy's *Looking Backward,* 2000–1887, published in 1888, held out to a million readers the promise of a future utopia without the debasing effects of trade. In 1894 Henry D. Lloyd attacked the trusts in *Wealth Against Commonwealth.* In 1902 *McClure's Magazine* launched a series of articles indicting municipal politics and big business. Theodore Roosevelt gave the name of "muckraking" to this type of journalism. However, he had given encouragement to it by his rebuke to "malefactors of great wealth."

A series of harrying congressional investigations of big business accompanied the attacks. "We are passing through a reform —yea, a revolutionary period in business affairs," Henry Clews wrote in the *Annals* of the American Academy of Political and Social Science for July 1906. He called on banking and insurance interests to drop their policy of secrecy, which, he said, was "obviously in defiance of public sentiment."

Another development of 1906 was the appointment of Ivy L. Lee, a former newspaperman, as publicity adviser to a group of anthracite operators. The mine owners had stirred the anger of the press by their haughty attitude in labour disputes. Soon after Lee's appointment it was announced that they would supply the press with all possible information.

Lee then sent to city editors a declaration of his policies, in which he said: "This is not a secret press bureau. All our work is done in the open. . . . If you think any of our matter ought properly to go to your business office, do not use it."

Retained by the Pennsylvania railroad the same year, Lee made information concerning accidents available to the press for the first time. In 1921 his firm issued its bulletin, previously called *Notes and Clippings,* under the title of *Public Relations.*

In 1923 Edward L. Bernays published *Crystallizing Public Opinion.* This book, describing publicity functions and techniques with an emphasis on social responsibility, did much to popularize the term public relations and to gain recognition for specialists in the field.

Meanwhile, men were being hired in the service of the federal government under such titles as "director of information," "editor" and "supervisor of information research." These provided a loop-hole in a congressional act of 1913, which forbade the spending for "publicity experts" of any funds not specifically designated by congress for that purpose.

In Britain, the Empire Marketing board began using large-scale publicity for the promotion of trade in 1924. *Report on the British Press* says of the Empire Marketing board that "before its demise in 1933 it had established the archetype of Government Public Relations Departments."

In Britain, as in the United States, appointment of public relations directors by government departments during World War II was the prelude to increased postwar emphasis on public relations. The British public relations journal *Persuasion* pointed out in its issue for the winter of 1949: "The war made a great difference to the relation between a local authority and its people. . . . When peace came, the climate for formalized public relations was good."

One indication of the greatly heightened interest in the United States was the fact that many colleges were adding courses in public relations to their curriculums. Boston university established the first school of public relations in 1947.

Philosophy of Public Relations.—A realistic view of the public relations field avoids over-idealization on the one hand, or a cynical view on the other.

The basic purposes of a public relations department are the establishment and maintenance of good will. It is obvious that the more the organization does to merit this good will, the easier the task of the public relations director will be. When he invites public attention to his company in connection with some attractive phase of its activities, he cannot be sure of limiting the interest of the press or public to that particular area. The efficient public relations executive therefore works forcefully for the elimination of policies that he believes to be open to criticism.

A typical illustration of this point occurred at a conference in which plans for the construction of a winter resort were being discussed. Business executives associated with the project started with the assumption that it would provide only high-priced accommodations, since inexpensive ones would be unprofitable. The public relations consultant argued that low-priced rooms and meals should be offered also, in view of the fact that the project was backed by a railroad. His view was that a public service corporation would be inviting antagonism if it were associated with an appearance of exclusiveness. This opinion prevailed.

Following is another example of enlightened self-interest in public relations, cited by Glenn and Denny Griswold in *Your Public Relations* (Modern Industry Books, 1948):

"Suspicion and resentment had existed for years between neighboring small towns and agriculture on the one hand and San Francisco and its business interests on the other. . . . Mr. Lundborg" (general manager of the San Francisco Chamber of Commerce) "organized a committee of 83 leading farmers and of businessmen whose enterprises depended on agriculture. They sponsored a program of doing things to help farmers instead of boasting about the city's virtues. First they enlisted the help of newspapers, radio stations and grocery store chains to help dispose of an apple crop so abundant that it threatened ruin to many farmers. Within two weeks the surplus was lifted, prices had been maintained and farmers began to see some good in city business."

A significant sidelight on this story is the fact that it involved the public relations policy with which chain stores were combating campaigns to tax them out of existence. The method of an earlier day would have been merely to fight propaganda with propaganda. In this instance, propaganda was one of the weapons employed; but it was given powerful assistance by an intensive effort to win good will through service. Helping farmers to dispose of surplus crops was part of that program.

The public relations director or consultant frequently needs a high degree of persuasiveness in order to gain a hearing for a

long-range point of view in councils concerned with immediate commercial objectives. In order to be an efficient representative of his company he must also be a representative of the interests of its employees, of the local communities in which it has factories, of the retailers who distribute its wares, of the consumers who buy them, and of the public at large. It is not necessary for him to be an altruist in order to do this; he need only realize that it is easier to correct sources of irritation than to justify them.

Public relations consultants have stated that they could not have secured a serious hearing for some of their plans, involving immediate sacrifices for long-range objectives, if not for the respect engendered by their extremely high fees. On the other hand there have been many occasions, before as well as after the term public relations came into use, when businessmen have shown an innate talent in this area. For example, the suggestion box system, which later became a feature of thousands of public relations programs for maintaining employee morale, was used by the William Denny Shipbuilding company of Dumbarton, Scot., in 1880. Denny, after he had given many awards for ideas submitted by employees, said: "The scheme has the effect of making the workmen of all departments into active thinking and planning beings instead of mere flesh and blood machines."

Another Scotsman who showed a keen insight into some phases of public relations was Andrew Carnegie. During his boyhood, when he was an employee of the Pennsylvania railroad, Carnegie submitted to the *Pittsburgh Journal* an article on "the attitude of the city toward the Pennsylvania Railroad Co." In his memoirs Carnegie tells that this article brought him to the notice of the counsel for the railroad. Also, though he shared the weaknesses of industrialists of his era in other ways, he gave a building rent-free for the use of a co-operative store for employees.

Nevertheless, though early parallels can be found for every basic phase of public relations, as an organized activity it represents a major change in the philosophy of business—the recognition of the ultimate authority of public opinion. At the halfway mark of the 20th century, thousands of top-ranking business executives were devoting a major share of their time and planning to an activity that had been trivial or nonexistent in the programs of their companies a generation before.

Publicity as a Public Relations Tool.—When a policy has been set and the public relations representative is seeking publicity for it in news media, he must put his reliance not on techniques of persuasion but on his judgment as to what constitutes an acceptable story.

A story with intrinsic news value, simply and clearly presented, usually receives an objective hearing. A statement made in 1926 by Louis Wiley, business manager of the *New York Times,* is representative of a policy that gained wide acceptance with mass media: "If so-called publicity is legitimate news, it should be printed for the readers of the newspaper regardless of whether it benefits private interests or not. If it is not legitimate news, then it should not be printed, regardless of who may be pleased to have it appear."

In both large and small organizations, public relations departments are usually watchful for such publicity opportunities as anniversaries that may be of local or general interest, public events in which it would be logical for the president or some key official of the company to participate, incidents involving celebrities, and developments susceptible to treatment in text or photography as human-interest stories. In the handling of adverse news, such as that of accidents, experience indicates that the harm is minimized by candid answers to inquiries.

The policy on publicity expressed by Louis Wiley represented an important step forward for the public relations worker; but this did not mean that he was on an equal footing in a newspaper office with the paper's own reporters. The news value of a story had to be such as to be clearly and quickly apparent to the editor, who was constantly being flooded with copy by his own staff and the wire services.

In some cases the solution to this problem was found in the creation of news events—a practice that was not new but which was now followed with much greater respect for the judgment of editors. It became an important factor in the public relations programs of trade groups. For example, a group of soap manufacturers, anxious to combat the statement by some cosmeticians that soap was bad for the skin, turned to a public relations consultant, who advised formation of a cleanliness institute. This was not a dummy organization but one that conducted an actual cleanliness campaign, welcomed in public schools. It received widespread publicity. On another occasion a public relations counsel initiated soap sculpture contests on behalf of the industry. This type of oblique publicity was found to be of great value.

Similarly, when the National Cotton council was faced with the competition of paper bags with cotton ones as containers for feed, its public relations department sent emissaries to show farm wives how they could convert cotton feed bags into attractive dresses. Photography editors of newspapers and magazines were attracted by the novelty of the idea, which proved an effective stimulant for the sale of cotton.

The attitude of many editors toward this type of public relations was summed up by Stanley Walker in *City Editor:* "Once Irene Castle cut her hair, and her photograph was attractive. Barber shops, beauty parlors, hairnet manufacturers, the comb industry and the hat business were affected for better or worse. Businessmen are at the mercy of a million such whims. It is better for them to attempt some intelligent direction of these whims, so that they will know what to expect. Otherwise some morning they may find themselves ruined."[1]

A classic example of the unexplainable whims mentioned by Walker is chronicled by J. Henry Harper in *The House of Harper.* Discussing the publication of the novel *Lorna Doone,* Harper tells that at first this novel attracted little attention. Later, when the marriage of the marquess of Lorne (who had no connection with the book beyond the accidental similarity of his name) was headlined in the press, the novel was somehow associated in the public mind with this glamorous event, and its sales rocketed.

Publicity, which is capable of this freakish power, is a versatile instrument in the hands of a resourceful man or woman with newspaper experience. It proved a major factor in removing a once widespread prejudice against the game of billiards; it helped greatly to popularize bowling and other sports; and it has contributed to the making of fashions and literary and theatrical reputations.

Given an assignment that has a reasonable justification for its existence, a publicity man has many avenues of approach. A favourite one is to interest celebrities in the project, and use their names as a springboard. Another is to devise contrasts of a striking nature.

An illustration of a combination of the two methods occurred in New York city in the early 1920s, when a publicity man, admiring the work of an unknown artist, volunteered to bring it to public notice. A private exhibition was arranged for the artist's work, which included a series of panels depicting a boxing match. Several well-known fighters were then induced to come to a tea at which the pictures were shown. A Sunday newspaper devoted a full page to photographs of the artistic-pugilistic tea.

Publicity of this harmlessly playful type survived as an effective aid to some public relations programs. An instance of this was the formation, on behalf of doughnut manufacturers, of a mock-serious society known as the National Dunking association.

Perhaps the major significance of this type of publicity is that it permits imagination, judgment and energy to do the work of money. It is capable of putting a low-budget public relations office, representing a small business, a college, a church group, or a philanthropy, on a par with the most powerful organization.

Public Relations Advertising.—As some big corporations became increasingly aware of the importance of courting public opinion, they supplemented their publicity efforts with a new type of advertising—one that was not designed to gain business

[1]From *City Editor,* copyright 1934 by Stanley Walker. Published by J. B. Lippincott Company.

but to clarify their policies and improve their relationships with their employees, the local community and the public at large.

The Bell Telephone company was active in this field as early as 1908. After World War II Bell Telephone, unable to supply the demand for new installations, published a series of advertisements explaining why delays were unavoidable. The flood of complaints subsided to a point below the prewar average.

Several public opinion surveys revealed that the average American believed the profit margins of industry to be excessive. However, the popular idea of what constituted a fair percentage of profit proved to be substantially higher than the percentages that industry was actually earning. This was the basis for effective educational campaigns.

In public relations advertising by management in connection with labour disputes, a temperate policy, anticipating the day when the strike will be settled, has been found to be a wise one. During the strike at the General Electric plant in Bridgeport, Conn., in 1946, the company presented the view that wages must be geared to production, but avoided strident controversy. One advertisement was devoted to announcing that the strikers' insurance under the company's employee plan was being kept in force.

Industrial Relations.—Winning the good will of its employees is one of the major objectives of every industrial organization. The morale of a factory's workers affects many economic factors. Among these are the quantity and quality of production; the company's position in competing in a tight labour market for the services of skilled workers; its popularity or unpopularity in the local community, which in turn affects the treatment it receives from the municipal administration; and its reputation through the country as a whole.

No public relations technique can offset substandard wages or unsatisfactory working conditions. However, even a policy that is intended to be equitable may run into trouble if administered in impersonal, bureaucratic fashion. Accordingly, an efficient public relations director makes a strong effort to keep management sensitive to human values. Employees are informed of new developments promptly, before there has been an opportunity for these to be distorted by rumours. They are encouraged to submit complaints as well as suggestions. Advance proofs of institutional advertising are posted on factory bulletin boards. Facts on the company's earnings and prospects are made available. In some organizations, regular "job holders' meetings," similar to stockholders' meetings, are held. Issuance of publications for employees has become a standard practice.

An illustration of the scope of this work in a large organization was provided by the program of the International Harvester company. *Employee Relations,* a report by E. M. Claypool in *Public Relations Handbook,* edited by Philip Lesly, (copyright 1950 by Prentice-Hall, Inc.) states: "Organization of the Harvester employee relations program is divided into six main groups: labor relations, personnel, wage administration, salary administration, education and training, and group insurance. The activities of these groups are coordinated by a vice-president in charge of industrial relations who works in close harmony with the director of public relations. They use such industrial relations techniques as apprentice courses, student training, job training, supervisory training, vacations, collective bargaining, employees' benefit associations, group life insurance, hospital and surgical benefits, accident compensation, and scientific personnel selection and placement.

"An outstanding feature of the Harvester educational program is that any group of reasonable size may arrange for a course in any desired subject, whether the course is related to their present jobs or not. This policy encourages employees to develop hobbies and to broaden their intellectual horizons.

". . . Each plant has its own publication that acquaints employees with persons, departments, and activities removed from their immediate vicinity as well as those with whom they work."

Scope of Public Relations Departments.—Almost every form of the printed and spoken word, and of photography, is used in public relations work. At mid-20th century, many public relations departments included the following activities in their routine responsibilities: issuing news releases to newspapers, radio stations, trade journals and popular magazines; arranging press conferences; answering queries from the press and public; preparing text and illustrative matter for public relations advertising, pamphlets, employee magazines, manuals for the training of new employees, reports to stockholders and form letters; planning documentary motion pictures, recorded television programs, film strips, lantern slides, charts and recorded talks; planning and publicizing exhibitions and "open house" days at factories; and planning research surveys for gauging the opinions of employees, customers, or the general public. In addition, in cases where the product of the company is an expensive one, such as an automobile, the public relations department may have the duty of preparing a magazine for free distribution to listed customers. Some corporations issue special magazines for their stockholders. Public relations directors of trade organizations, long-established companies, and various institutions also have arranged for the publication of books, sometimes by well-known writers, telling the history of the organization or industry. These books are usually placed on sale through normal channels, but often are subsidized to assure the publisher against loss.

Some organizations employ not only a public relations director, with a staff under his supervision, but also a public relations consultant, to provide an outside point of view on questions of policy, or the public relations department of an advertising agency.

Most public relations work involves a combination of logical and psychological methods. Experience has repeatedly proved that exaggeration and distortion defeat their own purpose; but often it is possible to switch from an unpopular concept, expressed in a standardized term, to a popular, or at least an acceptable one, without doing violence to truth. Walter Lippmann, using the word stereotypes to describe these concepts of the mass mind in *Public Opinion,* influenced many public relations experts. An illustration of this type of thinking is the substitution in public relations advertising by labour unions of the term "union security" for "closed shop." Another is the use by manufacturers of "billiards" for "pool," which had taken on the connotations of shabby poolrooms.

Much specialization has developed in public relations work in areas such as banking, agriculture, education, philanthropy, etc. Also, many public relations executives specialize in the use of various media, such as audiovisual materials and stockholder reports.

Harlow and Marvin M. Black, *Practical Public Relations* (1947); Eric F. Goldman, *Two-way Street; The Emergence of the Public Relations Counsel* (1948). (J. Ay.)

PUBLIC SCHOOLS. In the United States this term is used to describe free, tax-supported, public controlled and directed, nonsectarian schools. The term public school in England includes not only the schools of ancient foundation such as Eton, Harrow and Winchester, but also schools of comparatively recent creation such as Clifton, Cheltenham and Marlborough. As forming part of the secondary school system of England (*see* SECONDARY EDUCATION) they are included in the official statistics as non-aided schools.

PUBLIC UTILITIES,[1] a designation for a special grouping of industries. These industries should be distinguished from state services or public works, which are administered as public functions and hence supported by taxation, and from that variety of industrial, commercial and agricultural undertakings which are usually comprehended under the term "private business." Public utilities, properly so-called, need not be privately owned. In almost every country a varying number of them are owned and operated by the state. But these publicly managed enterprises, instead of looking to the state for financial support, sell their services to the general public. Both publicly and privately owned utilities sell their services at prices which are not fixed in the open market but are governmentally fixed. This is the most important aspect of the process known as public utility regulation. Although economic and technical evolution is continually changing the character of these industries besides creating new ones, public utilities may be classified according to the generalized function which they perform in economic life.

The following have been treated as and classified into groups of public utilities: (1) services of transportation (common carriers); (2) services incidental to transportation; (3) services facilitating communication; (4) facilities providing power, light, heat and refrigeration; (5) facilities providing water and sanitation in urban communities; (6) facilities regulating water-supply for agricultural purposes.

HISTORICAL SURVEY

Public utilities are closely associated with our developing civilization, supplying wants so fundamental for communal living that government has at all times subjected them to some measure of control. With the growth of trade in ancient empires facilities providing transport and communication were set up. The governmentally maintained highway system of the Roman empire and its many aqueduct systems are celebrated ancient public works. The need of some system of public communication was so great that even our letter post has its ancient parallel. In the more populous ancient cities, systems of sanitation also became a necessity. Along with this came the recognition that services used collectively should be supplied by the state. Public utilities thus began as state functions. By the middle ages most

[1]The writer is indebted to the Macmillan Company for permission to adapt from his work, *Outlines of Public Utility Economics,* certain summaries for substantial portions of this article.

of the ancient public utilities had declined or virtually disappeared. By slow stages, upon the manors and in the mediaeval cities, these public facilities again appeared. Of great importance in British and American legal history is the fact that out of the economic and legal relationships of feudalism there arose the concept of a "public calling" upon which is based the present-day policy of public utility regulation.

The modern national state gradually supplanted the elements of the feudal system of social control. The expanding domestic system of manufacture was displacing the guild and manorial system of production; foreign trade was growing. National systems of transport involving highways and canals were undertaken and the regulation of utilities became national rather than local.

Effects of the Industrial Revolution.—The greatest impetus in the expansion of public utilities came with the industrial revolution. The factory system so stimulated production that the need for ever-expanding markets became the limiting factor in economic evolution. Cities grew as never before, creating a new municipal need for systems of water-supply, sanitation, transport, communication, illumination and finally of power.

But the philosophy of *laissez faire* was not fertile ground for extending public functions. Thus, although the rapid industrial changes intensified needs, the tendency was to give greater scope to private enterprise.

However, the evils of a system which left the supply of basic economic wants to private industry insufficiently regulated by government became too flagrant to be overlooked. Beginning about 1840 the revolt against *laissez faire* doctrines caused an enlargement of the scope of governmental action. The older public utility services were continued for the most part as public enterprises, while the newer services were supplied by private initiative under some form of public supervision and assistance. Thus emerged the modern notion of a public utility, distinct from strictly governmental services and strictly private business.

Need for New Utilities.—The beginnings of the modern postal system date back to the 15th century. In the 18th century England was covered with improved roads built by public authority or by private turnpike companies. The first canal in a new era of canal building was completed in 1761. The first steam railroad was built in 1825 and the first regular steamboat began operation in 1812. The steam railway developed into the backbone of land transportation, yet canals and inland waterways continued to serve as important arteries of commerce. With the coming of the automobile, in the United States as elsewhere, highway systems were reorganized upon an unprecedented scale. The motorbus and the motor truck made use of this development and soon were rapidly cutting into the short-distance traffic of steam railroads. After 1850, systems of rapid, world-wide communication were perfected. The commercial electric telegraph and the telephone are now of tremendous importance. (*See* TELEPHONE; TELEGRAPH.) After 1900 radiotelegraphy and after 1907 radiotelephony increased the varieties of means of communication. The ancient art of irrigation underwent a rebirth.

In the field of municipal public utilities local transportation was supplied, at first, by fleets of omnibuses in the '20s of the 19th century. The horsecar came in the 1830s. Artificial gas for illumination was introduced commercially in London in 1812 and was widely in use for lighting by 1840. A new development in water-supply systems appears to have been introduced by the municipality of London in 1583, followed by Plymouth in 1585 and by Oxford in 1610. Boston in 1652 installed the first modern central water-supply system of the gravity type in America. Central water-supply systems became general in the large cities by 1820. Growing out of experiences in the cholera epidemic, British sanitary authorities put forward the trilogy of public hygiene—street paving, canalization and water supply. As a final achievement in the development of municipal sociology came a new city-planning movement, begun in Paris about 1850. (*See* TOWN AND CITY PLANNING and related articles.)

New public utilities centring in cities developed out of the industrial applications of electric power. In 1882 the first central station for electric lighting began operation in the United States. By 1885 electric power was applied to street-railways. The first hydroelectric plant began operation in 1882, the precursor of a new movement in power production.

In this historical survey it is important to note that public utilities were not definitely segregated from public functions until the *laissez faire* philosophy of the 18th century restricted the scope of governmental activity and created institutions and processes whereby the supplying of these changing public needs could be left to private initiative. Industrial interdependence now prevails. Thus public utilities, although privately owned, were subjected to governmental regulation. The term socialization has been chosen to describe this latest phase of utility development because it implies that government may actively promote these enterprises through public ownership or arrive at the same result by creating private agencies and controlling them through well-conceived policies of regulation.

ECONOMIC CHARACTERISTICS

Developments in the engineering arts bring changes in economic organization. For instance, lighting of the home was transformed first from a self-sufficient household industry (as the making of candles) to a commercial competitive industry (the supply of candles, lamps, whale oil and petroleum), and then to monopolistic industry (electric lighting), where central sources of supply satisfy all demands. Perhaps the most significant economic conclusion founded upon these changes is that the social value of public utility services is increased and the economic cost of rendering them is reduced by a consolidation of enterprises. The individual user of water in urban centres no longer had to depend for his supply upon his own well, nor did he have to buy from one of several competing sources. He resorted to a single common source of supply along with other users. This was found to be more convenient, economical and, indeed, the only practical solution. But this process of integration of supply was a long process. In some public service industries it was not completely realized. The tendency toward monopoly, however, whether the result of a competitive struggle or brought about by legislation, became a fundamental characteristic of public utility business.

Every public utility must be in possession of the natural resource upon which that industry is based. A gas or electric company must have possession of sites for the location of its works; a transportation company must have rights of way and terminal sites. These properties must have strategic locations. Limitation in the choice of this agent of production tends to make the cost of acquiring or leasing these facilities greater than it would be if the industry had a wider range of choice. Furthermore, utilities must make allowances in advance for probable increase in the required capacity. For these reasons utilities are provided with the governmental power of eminent domain which makes possible the compulsory sale of private property. Thus the law recognizes that, socially considered, these properties are being put to the highest uses of which they are capable.

Fixed Capital Characteristics.—All the varying stages of transmutation of capital can be found in constructing public utility plants. The so-called free or liquid capital is changed into durable and specialized types of buildings, structures and equipment, capable of use in only one industry. The roadway and track of a railway, for instance, is so completely specialized that only the rails and rail-fastenings can be salvaged. These characteristics of specialization, durability and immobility are included in the definition of fixed capital. It is also well to bear in mind the specialized managerial and engineering talent required in constructing and operating these enterprises.

A utility which has assembled its plant and thereby incurred heavy construction costs of a fixed character anticipates that the product can be sold at a profit. If expectations are not realized the utility will suffer a pecuniary loss because the government has not generally undertaken to secure the utility against such risks. It is therefore highly important that each enterprise take into account the economic principle of proportionality which requires that enterprises be so planned that the maximum of physical output may be secured at the lowest possible money cost and that

this maximum supply does not exceed the reasonable, long-run demand for service.

But there is another aspect of the matter. Technical improvements involving much fixed investment of capital are also more economical. A double-track railway has more than twice the efficiency of a single-track railway. Electrical generators of large capacity cost less per kilowatt than do generators of small capacity. The cost of operating large plants thus tends to be less than for small plants. Public utilities are therefore anxious to increase the volume of business. Economical operation is also secured by interconnection of power sources into so-called super-power systems. A super-power system consists of two elements: the utilization of highly economical generating stations, steam or hydro, and the interconnection of power stations by transmission lines.

Not only is the fuel consumption per unit of output reduced by using only large steam plants but the investment cost per unit of capacity is also lowered. By interconnecting such power systems the reciprocal sale of power from one system to another is made possible, and a common reserve is made to serve for a large area. Co-operative action thus ensures the utilization of surplus power, safeguards the service from interruptions and secures the advantages of long-hour use of investment by building up the diversity of use. This movement for interconnection grew particularly in the instance of natural gas and electric utilities.

Availability of Utility Services.—There are also peculiarities arising out of the time when the demand of customers comes, and these have a special influence upon cost of production. All public utilities must stand ready to supply their services when demanded, and from this point of view utilities may be divided into two classes according to the ease or difficulty with which they meet this situation.

The first class comprises the utilities which must adjust themselves to demand variations by having constantly ready a productive capacity equal to or exceeding the maximum demand for service. Thus utility plants will have spare capacity for service at other times in the shape of idle equipment and reserves of employees. This class of utilities has been called the service type and is exemplified by electric utilities, telephone and telegraph utilities, the different kinds of transportation utilities and the postal service. There the nature of the service is such as not to permit of delay if it is to be performed efficiently. Technical development has not been successful in making available for instant use surplus service which existing equipment might have produced at times of low demand. Changes in the volume of business can not be met by a policy of meeting peak requirements in part by stored supplies of the past. This has a tendency, therefore, to increase the cost of operation.

The second class consists of those utilities where the inequalities in customers' requirements may be met, at least in part, by a policy of production and storage of surplus to meet future deficiencies. This class has been called the product type. It is exemplified by water and gas utilities which may produce at a uniform rate, impounding the water and storing the gas not required to meet the immediate demands against the excess demands of the future. Storage facilities thus enable the product type to operate at a uniform output within the productive limits for which the plant was designed. Utilities of the second class need have a producing capacity equated only to meet an average demand, but they must provide storage capacity.

Therefore, it is necessary to compare the operating efficiency of the product-type utility, based upon a constant output with costs enhanced by an added investment in storage facilities, with the operating efficiency of the service-type with its lessened efficiency resulting from a variable output and with costs enhanced by standby losses and the carrying charges for idle equipment. The services of public utilities are thus conditioned by factors which tend to differentiate them from other business enterprises. They minister to wants which are regarded as basic. From a social point of view they are necessary economic functions because they are the basis for the specialization of occupations and the interdependence which exist in modern economic society.

SOCIAL CONTROL OF PUBLIC UTILITIES

Public service enterprises are regulated by governments throughout the civilized world. It is impossible in this article to trace this development or to outline the modern structure of regulation. Those desiring a detailed presentation are referred to the bibliography. In this summary is mainly given a discussion of the development of social control of public utilities in Anglo-American countries. The regulation of national systems of transportation and communication is also excluded except in so far as their prior development has influenced the course of regulation of local utilities.

Munn v. Illinois Decision.—The legal basis of public utility regulation may best be disclosed by considering the famous decision of the U.S. supreme court in *Munn* v. *Illinois* (94 U.S. 113 [1877]). In this decision is focused the common historico-legal background of public utility regulation in both the United States and Great Britain. *Munn* v. *Illinois* involved the validity of an Illinois statute fixing maximum rates for storing grain in elevators at Chicago. Munn had been engaged in the elevator business since 1862, long before the enactment of the statute, and had been in the habit of charging rates fixed by agreement among the elevator owners in Chicago and had continued to charge these rates although they were in excess of those fixed by the act. Munn was convicted and fined in the state courts but appealed to the U.S. supreme court upon the ground that the act violated the 14th amendment in that it deprived him of his property without due process of law.

Chief Justice Waite, in upholding the validity of the statute, said in substance that under the circumstances in which the elevators were being operated in Chicago (*i.e.*, standing in "the very gateway of commerce and taking toll from all who pass") they had become business "affected with a public interest and had ceased to be *juris private* only." This was not his own language but was quoted from Lord Chief Justice Hale who had penned it about 200 years before in England. This legal doctrine, he said, had been a rule of the law of property ever since; that under this rule and in exercising the police power of the state, "it had been customary in England from time immemorial and in America from its first colonization to regulate ferries, common carriers, hackmen, bakers, millers, wharfingers, innkeepers, and so forth," and to fix maximum charges. In further explanation of this "public interest" doctrine, the court said that private property is being used "in a manner to make it of public consequence, and affecting the community at large. When, therefore, one devotes his property to a use in which the public has an interest, he, in effect, grants to the public an interest in that use, and must submit to be controlled by the public for the common good, to the extent of the interest he has thus created. He may withdraw his grant by discontinuing the use; but, so long as he maintains the use, he must submit to the control."

In a later case (*Charles Wolff Packing Co.* v. *Court of Industrial Relations of the State of Kansas*, 262 U.S. 522 [1923]), Chief Justice W. H. Taft of the U.S. supreme court gave further precision to this "public interest" doctrine by saying: "In a sense, the public is concerned about all lawful business because it contributes to the prosperity and well-being of the people. The public may suffer from high prices or strikes in many trades, but the expression 'clothed with a public interest' as applied to a business means more than that the public welfare is affected by continuity or by the price at which a commodity is sold or a service rendered. The circumstances which clothe a particular kind of business with a public interest, in the sense of *Munn* v. *Illinois* and other cases, must be such as to create a peculiarly close relation between the public and those engaged in it, and raise implications of an affirmative obligation on their part to be reasonable in dealing with the public."

Between 1923 and 1934, and particularly during the depression years, a series of cases involving the constitutionality of price regulation was decided by the United States supreme court. With a dissenting minority of liberals, the court ruled against the regulation of the resale price of theatre tickets in New York city and of the fees of private employment agencies in New Jersey. With-

out dissent it forbade the regulation of the retail prices of gasoline in Tennessee. A divided court decided against the regulation of competition among artificial ice plants in Oklahoma. This negation of the extension of regulatory power was halted in 1934 when New York was upheld in its efforts to stabilize the fluid milk supply industry and rescue it from price-cutting tactics through the fixing of minimum prices by a milk control board. The seeming confusion behind these contradictory opinions can be explained by noting that the trend was in the direction of extending the use of the police power in the interests of public health, safety, morals and the general welfare, while the hard core of public utility regulation in the interests of monopoly control continued without abatement.

Obligations of Public Utilities.—The affirmative obligations upon public utilities arising out of their peculiarly close relation to the public are usually spoken of as that system of rights and duties which constitutes the law of public service undertakings. Briefly, this law places upon a public utility the extraordinary duty to render reasonably adequate service to all who apply. It is required to serve them up to the limit of its capacity, with capacity being defined as the limit of profitableness. It may not let customers' wants go unsatisfied. Nor may it attach unreasonable conditions to contracts for service so as in effect to negative its duty "to serve all comers." Furthermore, it must serve without discrimination all customers similarly circumstanced. Finally, a public utility must observe more than ordinary care in the rendition of service in view of the dependence of the public upon such service and the hazards associated therewith. On the other hand, the same law concedes a public utility the right to collect a reasonable price, to render service subject to reasonable rules and regulations and to withdraw service under prescribed conditions after giving notice to customers. While customers are given the right to demand that a public utility live up to its duties, they are, on the other hand, required to accept reciprocal obligations.

In determining whether a given industry is subject to this coercive law of public utility the courts have adopted certain practical tests of both a legal and an economic nature. The economic tests look to the presence of elements of natural monopoly in such number and strength that competition cannot work successfully. Under these conditions fair prices, in the sense of competitive prices, are not realized. The power of the state will be used either to regulate industries so as to restore equality of bargaining power by maintaining competition and controlling competitive practices, or used to promote the inherent trend toward monopolistic organization by conferring upon such industries legal monopolies and then controlling their economic relations by means of the system of rights and duties just outlined.

From an economic point of view it is clear, therefore, that the concept of a public utility is made up of two ideas: (1) the idea of monopoly; and (2) the idea of common necessity. Both must be present in order that an industry may become a public utility. Neither alone will suffice. The supply of housing facilities is a necessary economic function, and when it is furnished upon a competitive basis the customer is not coerced. But when, in emergencies such as the acute housing shortage (*see* HOUSING) during World Wars I and II, the consumer is forced to bargain for a necessity under conditions of temporary monopoly, the courts will uphold the regulation of rents. Yet the character of regulation will be such as to enable the industry to reachieve normal condition. The emergency having passed, as building operations are resumed competition again sets in and the reason for regulation disappears. The housing industry therefore represents a borderline case which, nevertheless, ought not to be classed as a public utility under normal conditions.

Legal Conception of a Utility.—When freedom of choice is seriously restricted—that is, when the coercion residing in private property makes itself felt as a monopolistic power—public interest arises in proportion as equality of opportunity to choose is restricted, provided that the wants supplied are recognized as a common necessity. Monopolization of a luxury will not call forth regulation, for public opinion is the arbiter in the selection of those common economic needs whose monopolization engenders regulation. The concept of public utility thus becomes a legal instrumentality to achieve an improvement of the standard of life. In a society which is accustomed to look to governmental initiative for the supply of common needs, the facility will be supplied as a public function. On the other hand, a society which is distrustful of the state will leave the supplying of such common needs to a private agency under a franchise privilege, not as a matter of common right, but as an agency of the state.

Since the law had long recognized the rights and duties of public utilities, this legal conception attained a certain fixity in the form of legal rules. But the number and kind of industries that may be subjected to these rules is not fixed. It may be said that the legal notion of public utility is that of a fixed concept with a changing content. The industries at any time recognized as "clothed with a public interest" are not necessarily the industries which may legally be classified as public utilities at another time. The industrial and political situation as mirrored in public opinion will determine: (1) the number and kind of industries classified as public utilities; (2) the elaboration of the system of rights and duties which make up the institution; (3) the regulating agencies and instrumentalities employed (whether the legal rules and decrees of courts or the charters, special franchises and statutes of legislatures); and (4) the subordinate administrative standards which are evolved in practice. The trend in the development and application of the institution will be a resultant of the amount of social inertia, of the pressure of the economic environment and of the influence of intellectual progress. Special attention should be directed to these dynamic factors: (1) the growth and extension of monopoly; (2) war and other conditions creating special emergencies; (3) the movement for conservation of natural resources; (4) the movement for public ownership.

Regulation in the United States has been accomplished in three distinct ways: (1) judicially by means of suits at law where the common law duties and rights of public utilities are applied in specific cases; (2) legislatively by means of corporate charters or special franchises; (3) legislatively by means of the police power of the states or its federal equivalent, the power of congress over interstate and foreign commerce. Judicial regulation is the oldest and constituted almost the only form of control during the first half of the 19th century. Legislative regulation later largely supplanted judicial regulation, but the latter remained in the background as a potential agency which might become active again if legislative regulation should disappear. The function of the judiciary by 1898 had been restricted to the review of legislative and administrative acts.

Legislative regulation by means of the charter or special franchise was the next to be tried. The special franchise is now generally conferred under constitutional or statutory authority by local governments. The method of special franchise regulation is applied to so-called local public utilities, furnishing telephone, gas, electric, water and transportation services in local communities.

The weakness of legislative regulation by charter was that the maximum rates therein provided were largely in excess of those actually charged by the companies. Competition of carriers with each other, the decreasing unit cost of operation on account of increased utilization of plant capacity, the decline in the level of prices after the Civil War, continuous improvements in technique, made necessary and possible the rendition of service at rates below those fixed in the charters. The failure to provide adequately for financial and accounting control enabled the issuance of more stock and the padding of investment accounts, thus vitiating the control based upon net income. Special franchise regulation followed the procedure applied in the case of carriers. Maximum rates were fixed in the local franchise of telephone, gas, electric and water undertakings. These maximum rates soon became obsolete because the growing business of the companies required more complex and flexible rate schedules. Moreover, the companies began to appreciate that increased earnings, both gross and net, could be secured by means of rate reductions.

When state legislatures in the case of national carriers and local councils in the case of local utilities attempted to adjust these rates downward, they were met by the objection that the change would violate a contractual obligation and confiscate the property of the companies. Only when the franchise was silent on rate questions or when the power to alter, amend or repeal the terms of franchises was reserved, could the power to regulate rates or service be exercised by state or local legislatures. Another evil that had crept into the administration of public utilities as a result of the ineffectiveness of rate control was discrimination in rates. This was also induced by the fact that competition had never been entirely eliminated. Added to this, in the case of the limited term franchises of local utilities, was the growing insecurity of tenure. Failing to obtain a renewal the properties would be worth only their scrap value. Often there were no provisions for public purchase or for purchase by some other grantee at the end of the franchise period. The inducement was too great, therefore, to manipulate operations so as to enable investors to recoup their capital out of earnings.

About 1870–80 a policy was adopted of fixing rates by direct legislation. Legislatures realized that statutory regulation should be general rather than specific; that the rate and service problems require continuous attention; that the subject matter of statutes should be the laying down of principles and standards; that the new policy of continuous regulation required an effective agency, sufficiently informed by experience to carry legislative standards and principles into effect. This agency is the modern administrative commission, acting as an agent of the legislature. All states except Delaware set up regulatory commissions with varying jurisdictions. The Interstate Commerce commission (1887), the Maritime commission (1938), the Federal Power commission (1920) and the Securities and Exchange commission (1935), were established as federal commissions to regulate the interstate operations of national utilities. The administrative commission applies the common law rule of reasonableness to the concrete facts in each case and names the particular rate or service regulation reasonable under the circumstances. Practically all states prohibited discrimination in rates for service. This legislative injunction was made operative in connection with another one calling for publicity of rates and providing that only rates and regulations on file and approved by the administrative authority are the lawful rates. In six states designated local utilities continued to be controlled by means of franchises.

Regulation of all public utilities was hampered by the insistence of the courts after 1898, when the epoch-making case of *Smythe* v. *Ames* was decided, upon defining the basis for rate-making which commissions might use. The major conflict was over the weight to be accorded reproduction costs as compared with actual original costs in the determination of the "fair value" of the investment. With the rise in the levels of prices, particularly after 1914, commissions were inclined to use the standard of actual investment costs while the utilities were contending for reproduction costs. In a series of decisions culminating in *McCardle* v. *Indianapolis Motor Co.* (272 U.S. 400, 1926) the courts upheld the position of the utilities. But the courts receded from this extreme position after the depression set in and in 1942 in *Federal Power Commission* v. *Natural Gas Pipeline Co.* (315 U.S. 575) conceded that the particular formula of rate-determination was within the discretion of commissions, so long as the result was not arbitrary or confiscatory. This decision definitely revitalized regulation by commissions.

REGULATION IN EUROPE

On the continent of Europe practically all of the telephone and telegraph systems and so many of the railroad systems became nationally owned and operated that there is little opportunity for the development of anything like the Anglo-American system of public utility control. This also holds true in a large measure of local utilities. Where local utilities are privately owned they are operated under franchise contracts with the municipalities.

Great Britain.—In Great Britain until 1948, railroads and so many of the local utilities were in private hands as to cause considerable development in policies of social control.

Regulation of public utilities in England was accomplished by the method of private bill legislation, a special act of parliament for each undertaking performing the double function of conferring a franchise and of laying down regulatory standards. Usually certain applicable general laws were by reference made a part of the special act, such as the legislation controlling the acquisition of land by condemnation as set forth in the Lands Clauses Consolidation act of 1845.

Other important general legislation was contained in the following: Railways Clauses Consol. act, 1845; Companies Clauses Consol. act, 1845; Waterworks Clauses act, 1847; Gasworks Clauses act, 1847; Harbours, Docks and Piers Clauses act, 1847; Tramways act, 1870; Electric Lighting (Clauses) act, 1899.

In certain cases of common occurrence special legislation by parliament establishing public service undertakings was made unnecessary by permitting some appropriate department of the government to issue provisional orders under general legislation after due inquiry. But full parliamentary control was retained by requiring confirmation of provisional orders, either by parliament itself or, in some cases, by an agency such as the board of trade, made effective by resolution of each house of parliament.

The English system of regulation was, accordingly, comparable to the charter or special franchise system in the United States. Legislation of this type were the Gas Regulation act of 1920, the Electricity Supply acts of 1919, 1922 and 1926 and the Railways act of 1921. The focal point of control was the regulation of rates. In the case of private gas companies the first method of control, after a brief preliminary period of competition, was the so-called "official revision system." Maximum rates and maximum dividends were fixed in special acts but the power to reduce rates was given to the court of quarter sessions.

Later another method, the system of sliding scales, was used, the adoption of which was optional. There was established a standard selling price for gas and a standard maximum rate of dividend. Then it was provided that the dividend rate might vary in inverse ratio to the rate of charge.

In order to bring about mergers and reorganizations in the electrical industry which would make possible the generation of electricity in large units and the attainment of greater economy and efficiency, the Electricity act of 1919 created a board of electricity commissioners of five members, appointed by the minister of transport with the approval of the board of trade. Most of the regulatory powers over electric undertakings vested in governmental departments were transferred to this body. On the whole the act failed to achieve its end because many public and private authorities refused to co-operate. Accordingly the Electricity act of 1926 created a central electricity board with power to carry the "scheme" prepared by the electricity commissioners into effect.

With the inauguration by the Labour government in 1945 of the policy of nationalization, the remaining segment of private ownership of utilities passed into the hands of the government. Communication facilities (postal service, telephones and telegraphs) had long been a government monopoly and operated by the central government previous to World War I. The war period added the cables and wireless services. The British Broadcasting corporation became a public agency operating all radio broadcasting.

World War I had demonstrated the need of further coordination and consolidation of railway transport. This was accomplished under the Railways act of 1921, when 123 companies were consolidated into four great regional monopolies. The period between World Wars I and II seems to have brought the realization that co-ordination of domestic water transport and highway transport with railway transport was necessary. Consequently, when all forms of domestic transportation were nationalized on Jan. 1, 1948, under a minister of transport, he was required to set up four regional railway executives, a dock and inland waterways executive, a road transport executive, a hotel executive and a London transport executive.

In electricity supply, although the Central Electricity board had succeeded in establishing the British grid and was by 1938

supplying more than 97% of the energy required by the distributing undertakings of Britain, local agencies, both public and private, were continuing to distribute this energy as formerly. Complete nationalization of all phases of electric supply was accomplished on April 1, 1948, with the establishment of a British electricity authority.

Integration of gas supply was much less extensive. When on July 30, 1948, an act nationalized the entire artificial gas industry of Britain, the properties of 1,056 gas utilities, both public and private, were transferred to gas boards set up for 12 separate areas. Some national co-ordination between them was to be achieved by requiring their operations to be co-ordinated with the National Coal board. Thus public monopoly and ownership had become the dominant policy in Britain as well as on the continent.

Continental Europe.—Similar movements to bring about the large-scale generation of electrical energy were also being pushed in Italy, France, Germany and elsewhere. In Germany public joint-stock companies were created, similar to the German Railways company, with the shares in the hands of the private companies and cities co-operating under the plan. By means of these so-called "mixed undertakings" it was planned to separate the technical administration and financial management from the political arm of the government, at the same time providing for flexibility in the economic area within which service was supplied.

PUBLIC WELFARE LAW: *see* POOR LAW.

PUBLILIUS (less correctly PUBLIUS) **SYRUS,** a Latin writer of mimes, flourished in the 1st century B.C. He was a native of Syria and was brought as a slave to Italy, but by his wit and talent he won the favour of his master, who freed and educated him. His mimes, in which he acted himself, had a great success; he was perhaps even more famous as an improvisatore, and received from Caesar himself the prize in a contest in which he vanquished all his competitors, including the celebrated Decimus Laberius. All that remains of his works is a collection of Sentences (*Sententiae*), a series of moral maxims in iambic and trochaic verse, which has been much interpolated with later extracts.

The best texts of the *Sentences* are those of E. Wölfflin (1869), A. Spengel (1874) and W. Meyer (1880), with complete critical apparatus and index verborum; recent editions with notes by O. Friedrich (1880), R. A. H. Bickford-Smith (1895), with full bibliography; *see* also W. Meyer, *Die Sammlungen der Spruchverse des Publilius Syrus* (1877).

PUBLISHING. Publishing is the selection, reproduction and circulation of written matter. It is older than both printing and paper, though in modern times it has come to depend upon both. Printing from blocks was invented in China some time before the middle of the 9th century; printing from movable type was invented there by the middle of the 11th century. But at neither time was printing thought of or encouraged other than as an excellent device for avoiding the errors of transcription that often marked the work even of the best manuscript scribes and copyists. In Europe, printing from movable type was invented by the middle of the 15th century. But there, as in China, its major advantage over older methods of reproduction was thought to be the standardization of scripture and of official texts. Neither in Asia nor in Europe was printing viewed at first as being useful in the wide dissemination of literature, learning or political or religious discussion. As an instrument of publishing, indeed, printing had to fight its way; it became a great instrument of spiritual and intellectual development and theological and scientific discourse, but the earliest reaction, which persisted for centuries in the west as in the east, was one of opposition by church, government, university or other powerful interests, such as the Brahmin caste in India, to its use in giving wide publicity to certain ideas and information.

The Earliest Books.—Before the invention of printing and of paper, publishing was carried on by means of professional scribes or skilled slaves making numerous transcriptions of manuscripts on papyrus or parchment. Flourishing industries producing papyrus or parchment rolls for sale on which were inscribed the classics of ancient literature, religion and law were to be found in Egypt under the Ptolemies and in the major cities of Greece and republican Rome. Often under the Roman empire, as often under later western kings, princes, parliaments and presbyteries, censorship and intimidation controlled or attempted to control publishers' output, thus interrupting the continuous history of commercial publishing for long stretches. Yet these ancient enterprises were authentic prototypes of modern publishing houses. Their work consisted in selecting manuscripts for reproduction in quantity, in taking the risks of compensating authors in advance of public sale for rights to such manuscripts, in determining the size, price and format of editions of different titles, and in developing markets in which such editions could, by various means, profitably be sold. They were publishers in every modern sense of the word, even though their products were not yet books.

Books in the form with which the world has long been familiar, that is, made up of pages bound together at one side, had a long and obscure development of their own. By the 4th century the bound book had become moderately well-known, at least among the jurists of the later Roman empire. Its first real vogue, however, was in Ireland, two or three centuries later, the climax of the remarkable flowering of intellectual and religious spirit there being the Book of Kells, not infrequently mentioned, according to one authority, as "the most beautiful book in the world."

To distinguish it from the old *volumen,* or roll (from which, oddly enough, the word "volume," often used interchangeably with "book," is derived), the early bound book was called a codex. The codex became the typical book of the middle ages, and theological codices were produced in large quantities especially in the monasteries of various church orders, which were the publishing centres of the day. Codices in law, medicine, rhetoric and other fields of learning came from the rising universities which, in certain cities, early grasped control over the publishing industries from the church and the state. In such centres, the second-hand market was as well-known to mediaeval students as it became to those of the 20th century and to 20th-century textbook publishers as well. The difference was that the universities, as publishers but not commercial ones, strove (in these early efforts at price-fixing which became such a feature of publishing in the 20th century) to keep prices down for the students and thus encouraged the use of old copies. This also relieved the universities of producing large new editions every year.

The codex, of course, like the papyrus and parchment rolls that it replaced, was written entirely by hand. In the scriptorium or "writery" of the monastery, scribes more or less devoted to their work toiled during the daylight hours (fear of fire from artificial light prompted the monasteries to forbid work on books at night) copying page after page of ancient classics, thus laboriously accomplishing the great task of preserving them as well as the Bible. "After the scribe had finished his quaternion, or group of four sheets in eight leaves," writes Douglas C. McMurtrie, "his work was proofread in comparison with the original by a second person, and the sheets were then sent to the rubricator, who inserted titles, headlines, chapter and other initials, notes, and the like. If the book was to be illustrated, the sheets next went to the illuminator. After he had completed his work on the volume, it was ready to be bound." This procedure was not very different, in essence, from manuscript preparation in a modern publishing house—except that with modern printing and illustrating methods, these and related publishing tasks need be performed only once for an edition of many thousands, and not over and over again for every individual codex or book.

Printing and Publishing in Modern Europe.—Though the early history of publishing owes nothing to printing, Johann Gutenberg's invention of printing from alphabetical type gave a great boost to publishing in Europe after the middle of the 15th century. Gutenberg probably was not the first European to use movable letter type successfully. After his epochal achievement, however, Mainz, his home in Germany, became the indisputable

publishing centre of the continent, and Germany itself the source and fount of subsequent printing and publishing developments in the western world. Before 1500 about 30,000 books were printed in Europe; of these, more than two-thirds came from such great German centres of learning as Leipzig, Cologne, Basel, Nuremberg, Augsburg and Strasbourg. More important, it was Germans, trained in these cities, who introduced modern printing and publishing into Italy about 1460, where it played an important part in the spread of Renaissance culture and trade. Similarly, it was Germans, trained in turn in Italy, who carried the printing industry and modern publishing to France in the early years of the 16th century.

It was only then that a broadening of the lay market for books took place. In 1501 Aldo Manuzio designed the first books in small format, which eventually replaced the huge, elaborate and costly codex, just as the codex had replaced the awkward *volumen*. In succeeding decades, especially in France, much attention was given to typography, and names still commonly used for type faces in the 20th century became well-known, from the work, for example, of Claude Garamond and Robert Granjon. A customer of both of these typographical artists, Christophe Plantin, was the most famous of the early printers who became publishers. Born in France in 1514, Plantin fled from Paris in 1548 to escape religious persecution. He settled in Antwerp, Belg., and there made his fortune. In the end he returned to the good graces both of the church and the university, gaining from the Holy See the monopoly of publishing liturgical books for the Spanish empire, and becoming late in life, printer to the University of Leyden, itself a great publishing centre of the time.

Though many early printers remained faithful to the church and to their princes, the publishing of printed works quickly became one of the major means of organizing protestant and radical opinion in the late 15th and early 16th centuries. This naturally led to reprisals against the new publishing industry, especially in Germany, and in self-defense the publishers and printers organized into independent corporations and guilds of their own. These lasted until the 19th century in many countries. Where printing and publishing was not shut down or forced underground, as was the case in Nuremberg and Augsburg early in the 16th century, it was controlled by other means. Thus in France, as early as 1474, the new independent printers and their printed books were brought under the same licensing regulations by which the University of Paris alone had monopolized the work of the old scribes and the publication of their manuscripts. This was indeed a signal recognition of the rapid rise of the printer to publishing eminence; yet it was also an onerous burden to the new publishers who were out of sympathy with officialdom.

Between them, official controls on the one hand and guild restrictions on the other impeded the development of printing and publishing for centuries. On the continent, one result was the emigration of printers and publishers to England where, from 1476 to 1536, it is estimated two-thirds of all printers, binders and stationers were aliens. But even in England from 1534, when the Stationers company or guild was first organized into the monopoly of all English book publishing, to 1710, when the first copyright act was passed in the reign of Queen Anne, there was constant harrassment of publishers, which, in due time, was carried across the ocean to America as well. It was on an occasion during this epoch, when some freedom of publishing, bitterly won, was challenged by new efforts at control, that John Milton wrote his *Areopagitica* in 1644.

In France, control was more or less thorough until the revolutionary copyright law of 1793 freed publishing and printing from all existing monopolies. This freedom was short-lived, however, ending under Napoleon's First Empire and not restored until the declaration of the republic in 1870. French restrictions had a salutory effect on the publishing industries in the Netherlands and Belgium where, during the 17th and 18th centuries, large editions of the works of Molière, Boileau, Voltaire, Rousseau and others were issued clandestinely for the French market.

As is usual with excessively rigorous controls, they often were poorly enforced; and as is usual with official monopolies, they often bred strong, if *sub rosa*, competition. Both of these situations, whatever the prevailing atmosphere, permitted printed literature and learning to spread rapidly in Europe between the 16th and 20th centuries, and authorship and publishing to flourish because of it. The English Copyright Act of 1710 freed the individual author and enterprising publisher from monopolistic printers and recognized the right of both to negotiate for the best royalties and other terms for the publication of literary property. But this right had been recognized as early as Roman times, when publishers of the empire bid competitively for the exclusive privilege (for which they paid fees, not royalties) of duplicating literary creations. What was significantly new about the English act was its recognition of the right of the whole public to literary property after a specified term. That is the nub of modern publishing copyright; it protects authors in their rights to literary property and publishers in their acquisition of such rights; but more than that, it gives the public, increasingly eager for great published works, freer access to such property after a limited number of years—under Queen Anne's act the term was 14 years, with the author retaining the privilege of renewing for another 14 years; in the United States in the 20th century, it was 28 years, with the same privilege for another 28 years; in most other countries, the term is the remaining years of the author's life, plus 20 to 50 years.

The development of copyright practice since the early 18th century is an authentic clue to the growth of professional authorship and commercial publishing, and by the protection it affords, a stimulus to both. But it is more than that. It is also an authentic clue to the growing thirst for access to literature and learning among the populace who, with the centuries, became more and more literate. Roman usage and common law had acknowledged the author's right—if he could assert it—to his property in perpetuity. English and later continental statutes freed this property for public use after protecting the author and publisher for specified periods of time.

Toward Contemporary Publishing Practice.—Just as the monasteries gradually yielded their monopoly of publishing to the universities, and the universities to the corporations and guilds, and the guilds to the competitive printers, so the printers, under the pressure of this growing market for literary works, gradually surrendered their dominant position to the booksellers.

None of these transitions took place in a day. Even as early as the 1580s in England, the pressure of costs for printing equipment and the like forced printer-publishers to appeal to booksellers for capital and credit. Thus in 1582 Christopher Barker complained to the queen: "The booksellers being growen the greater and wealthier number have nowe many of the best Copies and keepe no printing howse, neither beare any charge of letter, or other furniture but onlie paye for workmanship . . . [with] the artifice printer growing every daye more and more unable to provide letter and other furniture, requisite for any good worke; or to gyve mayntenaunce to any such learned Correctours as are behovefull. . . ." Yet it was not until the 18th century that the bookseller had his great day as publisher. By then the reading public, especially in England, was growing much faster than before and trade in popular new books (as distinct from the earlier staples of the whole industry: Bibles, commentaries, textbooks, dictionaries and the like) was booming. To meet the new demands circulating libraries were established as early as the 1720s, and new authors were developing sufficiently large popular followings to be able to insult and dispense with their former aristocratic patrons. By the late 18th century booksellers whose names continued to adorn modern publishing houses as late as 1950—such as Constable and Longmans—had already become kingpins of the publishing industry. Only a few decades later in the new world itself, Harper, Scribner, Dutton, and Little, Brown had become well-known.

Thus, with the rise of the bookseller, contemporary publishing began, and with the more or less simultaneous rise of the novel and the novelist it flourished. Both developments reflect the ascendancy of the middle classes, and thus had their greatest vigour in England and America. They followed more deliberately

on the continent, where literacy was slower to become nation-wide and where extremes of wealth and poverty kept the middle class markets small.

The unity of bookselling and publishing, in turn, persisted far longer in England than in the United States, where the great development of new writers (after piracy of English titles was successfully abated late in the 19th century) gradually stimulated the creation of independent publishing houses which were neither printers nor booksellers. This change in turn brought with it new independent printers, binders and booksellers—the first two to produce, under contract, books arranged for by the new publishers; the second to sell those books to the ever growing public.

By the third decade of the 20th century still newer publishers appeared in numbers in England and the United States and in Germany and France on the continent, devoted almost exclusively to so-called trade books—that is, general books of fiction, popular biography and history, books of memoirs and inspirational psychology, books of sentiment and sentimental learning. Many houses among the older group and some among the newer ones as well continued to have all kinds of special departments for Bibles, other religious books, school and college textbooks, medical books and similar works that once were the foundation of the entire publishing industry. But the newer vogue was the trade publisher as such. The age of specialization had indeed set in, and nowhere more strongly than in the United States, where the industry was less encrusted with old traditions and thus afforded the most suitable soil for the new flowerings.

The Age of Specialization.—In the 20th century in the United States, as elsewhere, the number of new titles published each year grew steadily, except for dips in war years or their immediate aftermaths. At their peaks, about 35,000 new titles were published in Germany, 15,000 in Great Britain and 12,000 in the United States. These figures are not altogether commensurable; the definition of a book, almost since the time of the Romans, has always remained vague, and the categories for calculation in Germany, for example, were much broader than those used by the United States census. Even the United States census bureau has altered its definition of a book from decade to decade.

But whatever the actual figure, the relative size of the industry in the 20th century can be judged by comparing even its smallest annual volume of titles with that of earlier centuries. In the first half of the 18th century in England, for example, it has been calculated that the average annual number of new titles was about 93. The first quarter of the 19th century saw a jump to an average annual total near 600. This, as has been said, was reflected by the growth of the publishing industry itself. By comparison, the 20th-century totals make it clear why specialization in publishing could so readily be supported; indeed, they make it clear why specialization had to come.

Within trade publishing itself, moreover, again notably in the United States but not only there, the 20th century saw the development of hard cover reprinters, paper cover reprinters, specialized western story and detective story publishers, science-fiction publishers and others who profited greatly by concentrating on special books for special, but sufficiently large, markets. In distribution, moreover, the old fashioned bookseller—even the one who himself came to specialize in trade books—was supplemented by the book club, by other types of mail order houses and by the ordinary newsstand which accounted for the bulk of the sales of the paper cover reprints. How important these new avenues of distribution became is indicated by the fact that while most regular trade publishers still ordered editions ranging from 3,000 to 10,000 copies for most of their titles, for book clubs and paper cover reprinters editions often ran to more than 100,000 copies and not infrequently for the latter to more than 200,000 copies. Clearly the old middle class market had become, by the middle of the 20th century, a mass market, especially but not only in the United States. In England, where between World Wars I and II and after, the Penguin-Pelican series set such a high editorial standard, and in the United States, some of the publishers of cheap paper-covered books sought out and issued original works. In the main, however, those publishers, like the book clubs and others selling in mass markets, continued to look to the regular publishers for titles to reprint. Thus literary production in the form of books, and hence the literary health of their countries, remained such publishers' responsibility throughout.

Some bore it better than others, but virtually all sought to share it. To discover manuscripts for this publishing industry, new occupations thus became prominent after the first quarter of the 20th century. Two of these were most important: the manuscript scout, who often worked for publishers under contract by which his remuneration was a stated percentage of the retail price (usually ranging from 1% to 2%); and the literary agent, who universally worked for authors, handling all their business relations with publishers for compensation in the form of 10% of the author's royalties and other income from his literary production. The growth of the agency business reflected further specialization in the publishing industry by which the publisher, becoming more a business manager, passed over his editorial functions to others. It also reflected the broadening of the market for the work of authors, especially authors of fiction. In the 20th century to the old magazine and newspaper serial rights were added moving-picture rights, dramatization rights, radio rights, television rights, digest rights and a series of others, the sale of which required complicated negotiations and contracts and which, however much it might enrich them, most authors were themselves incompetent to handle.

In facilitating distribution of books, further specialized agencies appeared in many countries in the 20th century. These were advertising agencies, some of which merely added books to all the other products for which they sought to stimulate demand, others concentrating on books alone. Though in Germany the amount of money spent for the promotion of books remained less than 5% of the publisher's net return, and though in England it never rose much higher than that figure, in the United States 8% to 10% was a more likely figure, and for books with great sales expectations it often rose well above that amount. The spending of this money most effectively required skill and experience which the publisher often did not have; thus the development of advertising agency business in books.

Though trade books were the fastest growing part of the whole publishing industry in the 20th century, and paper cover reprints the fastest growing part of trade publishing, growth elsewhere also added measurably to the flow of books. Especially notable in the United States was the growth of the federal government as publisher—a development that reflected not only the rapidly increasing number of all kinds of government investigations, but also the growth of federal services to farmers and others not ordinarily reached by regular publishers and regular means of book distribution. Far smaller in volume was the production of the American university presses. Their work was largely in books of importance to science and learning which would, without the vigour of these presses, probably have gone unpublished and thus unknown.

All told, in 1945, according to the United States census bureau, almost 500,000,000 copies of books were printed in the United States alone. The history of the technological improvements in printing that made such production possible is a long one in itself, including the history of such familiar machinery as linotypes, cylindrical presses, rotary presses and attachments to them. Most of these came in around the turn of the 20th century; subsequent great improvements in their performance allowed them to keep up with the demand for books.

In the 20th century, moving pictures, radio entertainment, television broadcasts, the automobile, the massive illustrated magazines and other vehicles of entertainment and enlightenment occupied the attention of growing populations. All competed with the traditional book; but the book publishing industry itself enjoyed the most remarkable growth in its long and troubled history. In mid-century it was rising on the continent once again from the devastation of two wars. In the United States it remained one of the major channels of communication, one of the major forums from which were fed the spirit and the intellect,

Subscription Books.—One of the widest and most extensively developed methods of distributing books is by subscription: sales are assured by the canvassing and pledging of subscribers. Today reference works of all kinds—encyclopaedias, sets of children's books, some dictionaries, collections of popular novels—are distributed almost solely by this method and the value of the sales in the United States and elsewhere amounts to many millions of dollars.

Sales by subscription, it is believed, began in the 15th century when William Caxton is said to have initiated this method to finance the publication of *Mirror of the World.* The purpose was to ensure moneys for the production of this work and differed from the traditional practice, of having one sponsor or patron for the book, by enlisting the interest and money of many.

The idea proved attractive to printers and to authors but it was not until the turn of the 17th century that this form of distribution flourished. In most instances, the issue remained a single volume and the cost of production was assured by the persons who promised to buy the book. The method fell into disrepute after a time when some printers, selling a book in advance of publication, sold trash or no book at all.

In the 18th century larger sets of books were distributed by subscription. *Encyclopædia Britannica* in 1768 was one of the first. In some instances, where the cost of the initial production is excessive, prepublication offers are made and subsequent sales are continued under instalment or, as it is known in Great Britain, the hire purchase plan. Mark Twain in the United States adopted this idea for the distribution of Gen. Ulysses S. Grant's *Memoirs.* Albert Bigelow Paine says in his monumental biography of Mark Twain, that Twain was able to present General Grant, who needed it, the largest single royalty check, $20,000, ever given to an author up to that time, and, of course, before the volumes actually were made.

Perhaps the greatest recent venture in prepublication subscription was the publication of *Great Books of the Western World* in 54 volumes by Encyclopaedia Britannica, Inc., in 1952. It was the generosity of 500 founder prepublication subscribers which facilitated the general distribution of this costly work.

According to the American Textbook Publishers institute the subscription sales of reference books to homes and offices and to schools and libraries in the United States alone were estimated at more than $75,000,000 for the year 1950.

PUCCINI, GIACOMO (1858–1924), Italian operatic composer, was born at Lucca on June 22, 1858, of a family already distinguished in music: his great-great-grandfather Giacomo, great-grandfather Antonio, grandfather Domenico, and father Michele, having all been professional musicians. He was educated at the Milan conservatoire where he studied under Ponchielli. In 1889, *Edgar* was performed at La Scala, and in 1893 his *Manon Lescaut* in Turin. The former, based on *La Coupe et les lèvres* of Alfred de Musset, was a failure, but the latter, founded on the well-known story of the Abbé Prévost (which had been previously treated by three other composers, Halévy, Auber and Massenet) was favourably received, and still holds the stage. Its success was as nothing compared with that of the work which followed it, the sparkling *La Bohème* (Turin, Feb. 1, 1896). The libretto is based on Mürger's novel from which four scenes are taken, and the skill and resource and effectiveness with which they are treated leave no room for doubt as to the merits of the work. In *La Tosca* (Rome: Jan. 14, 1900), based on Sardou's tragedy, Puccini had an altogether different task, of which, however, he acquitted himself no less successfully. The work contains some of the strongest and most genuinely dramatic music which he ever wrote, and like *La Bohème* has enjoyed unlimited popularity at the hands of the general public from the first.

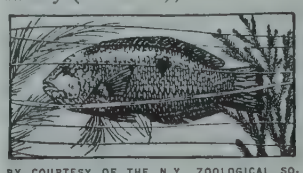
Madame Butterfly, on its first performance at La Scala on Feb. 17, 1904, was pronounced an absolute failure. Probably the libretto of the opera, with its unusual setting in Japan, had at least as much to do with this result as its music, but the Milan public's unfavourable verdict was reversed when the work was heard again at Brescia three months later, and since then its popularity has been prodigious and world-wide. If equal success did not attend its successor *La Fanciulla del West* (The Girl of the Golden West), this was accounted for by the unsatisfactory character of its "book" and by the undoubted inferiority of its music, so that the work, though favourably received when first performed in New York (Dec. 10, 1910), has never found general favour. Of the one-act operas *Il Tabarro, Suor Angelica* and *Gianni Schicchi,* which followed, all contain clever and characteristic music, but only the third, based on a most amusing libretto, has kept its place in the general repertory. As regards *Turandot,* the composer's last work, which he had not quite finished at the time of his death, and which was completed by Alfano, and produced at La Scala on April 25, 1926, critical opinion has been sharply divided. While some condemn it severely, others reckon it the composer's finest achievement. Puccini died at Brussels on Nov. 29, 1924.

See A. Weissmann, *Giacomo Puccini* (Munich, 1922); A. Fraccarroli, *La vita di G. Puccini* (Milan, 1925); and Wakeling Dry, *Giacomo Puccini* (*Living Masters of Music*) (London, 1906); V. J. Seligman, *Puccini among Friends* (1938); R. Specht, *Giacomo Puccini, the Man, His Life, His Work* (1933).

PUCHTA, GEORG FRIEDRICH (1798–1846), German jurist, was born at Kadolzburg in Bavaria on Aug. 31, 1798. His father, Wolfgang Heinrich Puchta (1769–1845), was a legal writer and district judge. From 1811 to 1816 Puchta attended the gymnasium at Nuremberg, and in 1816 he went to the University of Erlangen, Bavaria. Taking his doctor's degree, he established himself there in 1820 as *privatdozent* (teacher recognized by the university) and in 1823 was made professor extraordinary of law. In 1828 he was appointed ordinary professor of Roman law at Munich; in 1835 he took the chair of Roman and ecclesiastical law at Marburg. But he left that post for Leipzig in 1837, and in 1842 he succeeded Friedrich von Savigny at Berlin.

In 1845 Puchta was made a member of the council of state (*Staatsrat*) and the legislative commission (*Gesetzgebungskommission*). He died in Berlin on Jan. 8, 1846. His writings include *Lehrbuch der Pandekten* (Leipzig, 1838), in which he elucidated the dogmatic essence of Roman law, and the *Kursus der Institutionen* (Leipzig, 1841–47), which gave a clear picture of the organic development of law among the Romans. Other works were *Das Gewohnheitsrecht* (Erlangen, 1828–37) and *Einleitung in das Recht der Kirche* (Leipzig, 1840). Puchta's *Kleinezivilistische Schriften,* a collection of 38 essays on various branches of Roman law, was published posthumously in 1851 by A. A. F. Rudorff. The preface contained a biographical sketch of the author.

PUDDINGWIFE. A tropical American fish of the wrasse family (Labridae), called also doncella. It has a deep, compressed body, which is covered with large scales except on the head, has strong canine teeth in the front part of the jaw, and attains a length of 18 in. In colour the puddingwife is a vivid blue-green tinged with bronze or soft orange, though varying somewhat with sex and age. Spots and streaks of blue, especially on the head, fins and through the eye, add to its attractive appearance.



BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY

THE PUDDINGWIFE (IRIDIO RADIATUS), A TROPICAL FISH

PUDSEY, a municipal borough in the Pudsey and Otley parliamentary division of the West Riding of Yorkshire, England, served by the North-Eastern Region railway. Pop. (1951) 30,276. Area, 8.3 sq.mi. It has an important woollen trade and dyeing

and fulling mills. It was incorporated in 1900 and considerably enlarged in 1937.

PUDUKKOTTAI, a former princely state of southern India, lying between Tanjore and Madura districts of Madras, with which it was merged in 1948 as part of the Trichinopoly (*q.v.*) district. The area of the state was 1,185 sq.mi. Pop. (1941) 438,348. The chief, whose title was *tondaman,* was of the Kallan or robber caste. His ancestors received a grant of territory for loyal services to the British during the wars in the Carnatic at the end of the 18th century.

The town of Pudukkottai had a population in 1951 of 44,527. It is well laid out with several fine public buildings. A college affiliated to Madras university and a training school were established there.

PUEBLA, an interior plateau state of Mexico. Pop. (1950) 1,595,920. Area, 13,122 sq.mi., with its capital at Puebla (*q.v.*). On the southeast corner of the Anáhuac plateau, Puebla varies in elevation between 5,000 ft. and 8,000 ft., with numerous fertile valleys formed by the Sierra Madre Oriental which runs through the state. Endowed with a temperate, semihumid climate, crossed by main highways running southward from the national capital, and traversed by railway lines, Puebla is one of the most densely populated and important states of Mexico. Its strategic location and natural endowments in pre-Hispanic times are attested by innumerable archaeological sites and by its many towns and villages, notably Cholula, Atlixco and Tehuacán. Coffee, sugar cane, fibres, maize and cereals are its main crops, while onyx, gold and other metals occur in its richly veined mountains. Numerous short, fast rivers provide hydroelectric power. Its Nahuatl-speaking native peoples were highly developed at the coming of the Spaniards in the 16th century, and the latter founded many estates in this region, a main focus of their religious and economic activities. In the 19th and 20th centuries Puebla developed as an agricultural-industrial area in the important corridor between Mexico City and its main seaport at Veracruz. (Hd. C.)

PUEBLA, fourth city of Mexico and capital of the state of the same name (*q.v.*). Pop. (1950 est.) 140,000. It is in the centre of an important agricultural and industrial region of central Mexico. On highways to the federal capital (80 mi. N.) and main rail routes to the south and the Gulf of Mexico, Puebla is a metropolitan area which is considered the military key to the national capital and has been a commercial hub since pre-Spanish times. The city, founded by Spaniards in 1532 and named "Puebla de los Angeles," is on a broad healthful plain at 7,050 ft. above sea level in foothills of the Sierra Madre Oriental, within view of Mexico's three highest snow-topped volcanoes, Orizaba (18,696 ft.), Popocatepetl (17,883 ft.) and Ixtaccihuatl (17,338 ft.). It is a modern city whose historic and economic significance changed but remained dominant over many centuries.

Often termed the "Rome of Mexico" Puebla's architecture is notable and characteristic. Its cathedral is one of the largest and most sumptuous in Latin America, one of innumerable churches that testify to local piety. Puebla is renowned for manufacture of Talavera tiles and ware and other glazed tiles used locally and throughout Mexico for decoration. As the second most important city of colonial Mexico, Puebla has numerous historic public edifices. Notable are its Teatro Principal (1790), one of the first permanent theatres in the hemisphere. The impressive state legislative halls, municipal offices and main buildings around the public square date from independent Mexican times.

Supplied with electric power and centrally located, Puebla is a brisk industrial centre and has a long tradition in the manufacture of cotton and woollen textiles, glass, soap, pottery, leather goods and other light articles. Its onyx working is a specialty. Numerous small shops commingle with modern factories and foundries.

As the seat of a bishopric since 1550, raised to an archbishopric in 1903, Puebla is conservative and Catholic. A school of medicine, an academy of fine arts, a national university, and the Palafox collection of more than 100,000 volumes are significant landmarks. The city was named Puebla de Zaragoza after Gen. Ignacio Zaragoza (1829–62) who defended it against the French in 1862 in one of countless battles fought over this important place. (Hd. C.)

PUEBLO. The agricultural, town-dwelling Indians of the semidesert southwestern United States. They are of four distinct linguistic groups: (1) Shoshonean, comprising the seven Hopi (*q.v.*) villages in Arizona; (2) Zuñi, one town in western New Mexico; (3) Keres, comprising Acoma (*q.v.*), Laguna, Sia, Cochiti, Santa Ana, Santo Domingo, San Felipe, all but the first two in the Rio Grande valley; (4) Tano, consisting of three divisions, all near the Rio Grande; (*a*) Tiwa, five towns, of which Taos is the most northerly and best known; (*b*) Tewa, six pueblos (including Hano among the Hopi); (*c*) Jemez. The aggregate population is not far from 10,000, stationary or slowly decreasing, and approximately equally divided between the four speech groups. At the discovery in 1540 the Hopi, Zuñi and Keres may have been twice, the Tano three or four times, as numerous as to-day; the number of towns has also decreased, though some new ones have been founded. The Pueblos live on ancestral lands and cultivate these much as in the prehistoric period, though they have added wheat to maize and acquired some sheep, cattle, horses and asses; their houses, though larger, are of the old type; their religion has been successfully maintained by the Hopi and Zuñi and partly preserved alongside Roman Catholicism by the Keres and Tano. They are peaceable, gentle, unenterprising, quietly industrious and conservative. Physically they are fairly uniform; below average in stature, generally brachycephalic, with the skull somewhat flattened occipitally from the cradle board.

Of all the tribes of the United States the Pueblos are most similar to the advanced native peoples of southern Mexico, and the bases of their culture—maize-beans-squash agriculture, cotton growing and weaving, turkey rearing, painted pottery, masonry architecture, ritualism—are no doubt derived from these Mexican civilizations. They lack, however, a number of accomplishments characteristic of the Aztec, Toltec and Maya, such as metallurgy, political organization, calendrical system, ideographic writing, temples and pyramidal substructures. Since some of these traits have an age of about 2,000 years, the main influences emanating from Mexico are likely to have reached the Pueblos perhaps as much as three millennia ago.

South-western archaeology reveals a development through several stages: (1) Basket maker, possessing maize but apparently no other cultivated plants; no pottery or stone houses; spear thrower, but no bow; the physical type was long-headed. (2) Post-basket-maker, with crude pottery, slab-lined pit houses, the bow and arrow. (3) Proto-Pueblo, with the short-headed type which has persisted to the present; masonry, painted and neck-corrugated pottery, cotton, the turkey, the essentials of historic Pueblo culture, are already present. (4) Early Pueblo, in small house clusters; black-on-white and body-corrugated pottery; this is the era of most of the cliff dwellings and of the greatest geographical extension of Pueblo culture, ruins in Nevada and well north in Utah belonging to this period. (5) Great Pueblo period, with large towns like Pueblo Bonito and Aztec, centring in the San Juan drainage; the northernmost area had been given up, but the ruins in Chihuahua, like Casas Grandes, seem to be of this epoch. (6) Late Prehistoric Pueblo, with glaze-painted pottery; the San Juan area, and Chihuahua extension had been given up, but there were still Pueblos on the middle Rio Grande near El Paso. The Spanish discovery of 1540 falls in this period, which may be assumed to have continued until the influence of the missions became strong in the early 17th century, or until the general Pueblo rebellion of 1680. (7) Historic Pueblo, after the unsettlement caused by the rebellion; pottery is again painted instead of glazed, but both black-on-white and corrugated ware are long since forgotten; domesticated mammals have been introduced and sheep's wool tends to take the place of cotton for clothing.

In general, the Pueblos did not irrigate, although they knew how to choose farmlands containing sub-soil water. They are matrilineal and matrilocal, women owning the houses; but men order all public and religious matters. On the Rio Grande the clans weaken and moieties appear, until in the extreme northern towns

clans are, to-day at least, lacking. The religious edifice is the kiva, Spanish estufa, a small semi-underground structure for the performance of esoteric rites. Temporary altars are erected in these, often with ritualistic sand or meal paintings; feathers are "planted" as offerings at outdoor shrines; and for all religious organizations, offices and clans there are fetish bundles. The mythology is characterized by tales of emergence from the lower world and long tribal wandering. Cults take three chief aspects: (1) Youths are initiated into a communal men's society performing masked dances representative of gods and ancestors—kachinas. (2) Men and women are initiated individually into "fraternal" societies whose main function is curing, although there are also war and hunt societies; masks are little used. (3) Hereditary priests fast, entreat and pray for rain for the crops and communal welfare, and ultimately direct not only all religious affairs but the civil officials. Ritual symbolism is rich, especially as regards the idea of fertilization and number-colour-direction symbol patterns.

PUEBLO, a city of Colorado, U.S., on the Arkansas river at the mouth of Fountain creek, 112 mi. S. by E. of Denver, the county seat of Pueblo county and the second city of the state in size. It is on federal highways 50 and 85 and is served by the Colorado and Southern, the Colorado-Kansas, the Denver and Rio Grande Western, the Missouri Pacific and the Santa Fe railways. Pop. (1950) 63,685; (1940) 52,162. It lies at an altitude of 4,690 ft., near the coal fields of the state and many of the metal deposits, in an irrigated region of 50,000 ac., which produces 65% of all the cucumber seed grown in the U.S. and great quantities of red clover, cantaloupe, squash and onion seed. San Isabel National forest (600,000 ac.) is 20 mi. to the south and west. Pueblo is an important manufacturing centre. At Minnequa, on the mesa south of the city, is the plant of the Colorado Fuel and Iron corporation, Colorado's largest industry, employing 8,000 in the Pueblo mills, 5,000 men in mining and 5,000 in the manufacture of iron and steel. There are plants for meat packing, brooms, brick, tile, tents, awnings; also foundries and machine shops and a piston manufacturer. Pueblo is the seat of the state hospital for the insane (established 1879), and is the home of the Colorado state fair.

In 1806 Lieut. Zebulon Pike and his exploring party camped at the confluence of Fountain creek with the Arkansas ("The Forks," he called it), and the spot was visited by Maj. Stephen Long in 1820. A band of Mormons settled there temporarily in 1846–47 on their way to Utah. In 1850 a trading post was established. In 1858 a settlement (Fountain City) was made on the east side of Fountain creek, and the following winter (1859–60) the townsite of Pueblo was laid out and the first house was built on the site of the present city. Regular stage service to Denver began in 1862 but development was slow until the Denver and Rio Grande railroad reached the Arkansas in 1872. The two pioneer settlements were consolidated and chartered in 1870, when the population was about 500. By 1880 this had grown to 3,217. Other railroads reached the city in 1875, 1887 and 1888; the Colorado Coal and Iron company had its steelworks in operation in 1881; and in 1890 the population of the city was 24,558.

PUENTE GENIL, a town of southern Spain, in the province of Cordova; on the right bank of the river Genil or Jenil, a tributary of the Guadalquivir. Pop. (1940) 22,309 (mun., 27,552). It is on the Cordova-Malaga railway and is the starting point of the line to Linares. A bridge across the Genil, from which the name of the town is derived, joins the lower part of Puente Genil with the higher. The principal industry is the manufacture of olive oil. There are also flour mills and linen factories.

PUERPERAL FEVER, a medical term implying infection of some part of the genital passages following childbirth or abortion. The infection is most commonly of the raw surface inside the womb left after separation of the afterbirth, but pathogenic organisms may also gain entry through laceration of the mouth of the womb or other parts of the birth canal and may invade the blood stream, causing septicaemia.

History.—The disease has been recognized from the earliest days, and some of the greatest names in medicine have contributed to its study. In the 5th century B.C. Hippocrates stated, "If a woman in childbed have erysipelas of the womb she will usually die"; and this truth was manifest in the appalling mortality from the disease that persisted down to the 1930s. William Harvey (1651) was the first to describe the raw placental site as "one vast ulcer" in cases of puerperal fever. Charles White of Manchester, Eng. (1773), drew attention to the identity of puerperal and "surgical" fever; advised postural drainage of the womb in the lying-in period; and, by his vigorous insistence on cleanliness in the conduct of deliveries and on isolation of cases of puerperal fever, made a famous advance in the art of midwifery. Alexander Gordon (1795) noted that puerperal fever was a contagion, since it seized only such women as were visited or delivered by a practitioner or nurse who had previously attended patients affected by the disease. Jean Louis Baudelocque (1789) noted the greater incidence of the disease when hands or instruments had been introduced into the birth canal. I. P. Semmelweiss (*q.v.*) of Vienna (1847) rediscovered White's teaching and, noticing that the mortality from the disease among women attended by doctors and students who also practised dissection upon cadavers was far greater than among the women delivered by midwives, strenuously advocated washing of the hands in antiseptics before attending women in childbed.

During all this time, contagions were held to lurk in "humours" or miasmata which affected the air and the clothing and were thus borne from patient to patient directly or by an attendant. But in 1879 Louis Pasteur demonstrated a dotlike microorganism grouped in short chains which he had isolated from the lochial discharge of a woman with puerperal fever, and the bacteriological era of the study of disease had arrived.

These streptococci (*Streptococcus pyogenes, S. haemolyticus*) are only one, although the most deadly, of the causes of puerperal fever; others uncovered later are the anaerobic streptococci (which flourish in dead and dying tissues such as are to be found in the genital tract after long and injurious labour and difficult or injudicious instrumental delivery); the *Bacterium coli* and *Clostridium welchii,* inhabitants of the lower bowel; and various staphylococci commonly found on the skin and in skin eruptions of a pustular nature. Many of these organisms can be demonstrated in the vagina during pregnancy, and for some time the endogenous or autogenous theory of puerperal sepsis excused the neglect of rigid antiseptic precautions by the attendants of labour on the grounds that pathogenic germs were already present in the birth canal. However, in 1930 Leonard Colebrook stressed the fact that the anaerobic streptococci do not assume dangerous significance unless provided with the medium of bruised and lacerated tissues in which to grow and multiply and that such a development could be avoided by the utmost skill and gentleness in operative obstetrics.

In 1935 Rebecca Lancefield (U.S.) and Ronald Hare (England) showed that the haemolytic streptococci causing severe puerperal fever, scarlet fever, dangerous wound infections and tonsillitis were all of an easily identifiable group (A) which were not found in the normal birth passage before labour. Leonard Colebrook and his sister, Dora, then showed that in a series of cases of puerperal fever caused by the haemolytic streptococcus the infection had been conveyed by medical and nursing attendants or by other contacts who harboured the organisms in nose or throat. Thus was established overwhelming proof that puerperal fever is an easily preventable infection.

Infection and Symptoms.—The severity of the disease varies with the nature of the infective organism (that is, its powers of invasion of local tissues or the blood stream) and with the local and general resistance of the patient. In the gravest cases, the infecting organisms are commonly the pus-producing haemolytic streptococci and anaerobic streptococci and rarely staphylococci and pneumococci. Infection with the germs of gas gangrene (*Cl. welchii*) are rare but carry a very high mortality. Milder cases of puerperal fever are caused by infection with the nonhaemolytic streptococci and coliform bacilli.

The symptoms and course of the disease are similar to those of an acute wound infection. Fever with rigours usually arises on the third day after delivery, the pulse rate quickens and general prostration develops. The womb remains enlarged and tender, the discharges from it may be profuse and foul-smelling. Serious symptoms are persistent high fever and pulse rate, repeated rigours, sleeplessness, delirium and diarrhoea. Should the infection remain localized to the genital tract (as with coliform bacteria and nonhaemolytic streptococci), recovery is usual after a more or less severe illness (complicated by pelvic abscesses, etc.); but should invasion of the blood stream or peritoneum occur (as with haemolytic streptococci, anaerobic streptococci, *Cl. welchii*) the disease assumes the utmost gravity and, until about 1935, when sulfonamides were first used, accounted for about half the total maternal mortality in childbearing.

Prevention.—A main concern of those caring for women in childbirth is, therefore, to prevent infection from reaching or spreading among their charges. Until the development of antiseptic principles, the incidence and mortality of puerperal fever were horrifying, and the improvement reached by the first third of the 20th century was still unsatisfactory in comparison with that accompanying the prevention of sepsis after surgical operations. The more natural the labour and the less the interference, the lower the incidence of fever. Conversely, the more prolonged and extensive (*i.e.*, the higher up the genital canal) the interference and the greater the injury caused, the higher the risk of infection. Cleansing of the external genitals, disinfection of instruments and dressings and the wearing of sterilized gloves lessen the risk but will not wholly eliminate infection as it is impossible to render the skin surrounding the external genitals and anus absolutely germ-free. Hence the introduction of hands and instruments into the genital passage carries with it the risk of conveying organisms. Careful antenatal assessment of the size of the maternal passages by radiographic means increasingly prevented the necessity for these dangerous manoeuvres, and the discovery and use of powerful, yet safe, skin antiseptics with a prolonged action greatly lessened their risks. The local resistance of the tissues of the genital tract is lowered by bruising and injury and these can in large measure be avoided. The readiness with which infection may be conveyed by doctors and nurses harbouring organisms in the nose and throat has been clearly realized, and the wearing of an impervious mask over the nose and mouth during ministrations to childbearing women much decreased the danger. Antenatal measures directed to the general health of the pregnant woman—the treatment of coexistent disease such as diabetes, anaemia, tuberculosis or malnutrition—tend to raise the maternal powers of resistance to infection.

Treatment.—Treatment is, therefore, first of all preventive; the most stringent care is taken to adopt the same antiseptic and aseptic precautions in labour as for a major surgical operation and further by antenatal care to maintain the vitality at its best, avoiding all foreseeable complications in labour and generally securing natural delivery without interference. Loss of blood and exhaustion should be prevented or remedied by transfusion and restoratives. Complete emptying of, and free drainage from, the womb are essential, as are good nursing and attention to every detail of the mother's comfort and hygiene in the lying-in period. Until the middle of the 1930s, the curative treatment of puerperal sepsis consisted entirely of the above measures and, as has been said, they were successful in cases where the patient's good power of resistance, or the low virulence of the organisms, prevented the development of a generalized infection. Later, the sulfonamide group of drugs, first used by L. Colebrook and Meave Kenny in 1935, specific antidotes for infection by haemolytic streptococci, gonococci and pneumococci and *Bacterium coli*, caused a spectacular drop in the mortality of the disease; and, from the early 1940s, penicillin carried this victory over sepsis still further —more than three-quarters of the women who would previously have been doomed to die in this way now being saved. Before the era of chemotherapy, the haemolytic streptococcus accounted for about 75% of the total mortality from puerperal infection; the major instrument of death thereafter was the anaerobic group of organisms against which neither the sulfonamides nor penicillin had yet been shown to prevail and for which the only remedy lies in measures directed toward avoiding gross injury of the genital tract in labour. Deaths from puerperal infection by mid-century accounted for about one-sixteenth of the total maternal mortality, but the saving of a woman from death to leave her barren or an invalid is not enough. The incidence of the disease showed some reduction after 1935; but it was likely that the published figures did not present the real picture of the prevalence of the disease since, with sulfonamides and antibiotics, the patient's fever might be restrained below notifiable levels.

PUERTO CABELLO, a city and port of Venezuela, in the state of Carabobo, 34 mi. N. by W. of Valencia, the capital of the state. Pop. (est. 1950) 34,000. Puerto Cabello has railway and motor road connections with Valencia and from there with Caracas. Puerto Cabello is one of Venezuela's principal ports of entry, and has dock and warehouse facilities to handle a considerably greater volume of trade than it normally transacts. The protected area is small but accessible to the largest vessels calling at Venezuelan ports. Products of agriculture, chiefly coffee and cacao, and of the livestock industries, are the principal exports. Of additional importance to the port was the establishment there of the national dry dock and navy yard, which has two floating docks in operation for the repair of coasting vessels and small steamers, a large machine shop and building facilities for small vessels. Some industries took root in the city and in the area between it and Maracay and Valencia. Puerto Cabello suffered much in the War of Independence, changing hands several times and remaining in the possession of Spain down to 1823.

See A. Briceño Valero, *La Traición del Castillo de Puerto Cabello en 1812* (Maracaibo, 1941). (C. E. Mc.)

PUERTO DE SANTA MARIA, a seaport of southern Spain, in the province of Cádiz, on the right bank of the river Guadalete, with a station on the railway from Cádiz to Seville. Pop. (1940), 28,262 (mun., 29,197). Puerto de Santa Maria, commonly called "El Puerto," is probably the *Menesthei Portus* of Ptolemy. Its most important industry is the wine trade; there are also glass, liqueur, alcohol, starch and soap manufactures.

PUERTO LA CRUZ, principal port and largest city of the state of Anzoátegui, Venez., terminus of oil pipe lines and site of extensive oil refineries and storage facilities. In 1936 the former fishing village had only 1,879 inhabitants; by 1950, it had 28,315. (C. E. Mc.)

PUERTOLLANO, a town of central Spain in Ciudad Real province, on the Madrid-Ciudad Real-Mérida railway and at the north-east of the Valle de la Alcúdia. Puertollano is 2,345 ft. above sea level and has mineral baths. Its population (22,099 [mun., 24,676] in 1940) more than doubled in the 20th century.

PUERTO MONTT, a city and port of Chile, capital of the province of Llanquihue, located at the northern end of the gulf of Reloncaví, about 670 mi. S.W. of Santiago. Population (1943) 21,360. It is the southern terminal of the southern section of the Chilean state railways and is served by air lines. Its chief importance lies in its geographical location, which makes it the logical point of contact between the northern and southern sections of Chile. Puerto Montt is built on a plain surrounded by wooded hills and by grazing land. Its principal industry is lumber. The city was founded in 1853 by a group of German emigrants led by Vicente Pérez Rosales, and was named for Manuel Montt (*q.v.*).

PUERTO PRINCIPE: *see* CAMAGÜEY.

PUERTO REAL, a seaport of southern Spain, on the Bay of Cádiz and on the Seville-Cádiz railway. Pop. (1940) 12,510 (mun., 14,854). It is the Roman *Portus Gaditanus* and is probably the most ancient trading station on the bay.

It owes its modern name to the fact that it was rebuilt in 1488 by Ferdinand and Isabella. The port has good quays, a

dry dock and deep water for large steamers.

PUERTO RICO: *see* PORTO RICO.

PUFENDORF, SAMUEL (1632–1694), German jurist, was born at Chemnitz, Saxony, on Jan. 8, 1632, the son of a Lutheran pastor. He was educated at Grimma and the University of Leipzig, and then at Jena. Pufendorf quitted Jena in 1657 and became a tutor in the family of Petrus Julius Coyet, one of the resident ministers of Charles Gustavus, king of Sweden, at Copenhagen. As a result of Danish resentment of Gustavus' conduct in suddenly declaring war, Pufendorf with the rest of the suite was imprisoned. He occupied himself during this time in meditating upon what he had read in the works of Grotius and Hobbes. He mentally constructed a system of universal law; and when, at the end of his captivity, he accompanied his pupils to the University of Leyden, he was enabled to publish, in 1661, the fruits of his reflections under the title of *Elementa jurisprudentiae universalis*. The work was dedicated to Charles Lôuis, elector palatine, who created for Pufendorf at Heidelberg a new chair, that of the law of nature and nations, the first of the kind in the world. In 1667 he wrote, with the assent of the elector palatine, a tract, *De statu imperii germanici, liber unus*. Published under the cover of a pseudonym at Geneva in 1667, it was supposed to be addressed by a gentleman of Verona, Severinus de Monzambano, to his brother Laelius. The pamphlet made a great sensation. It was a direct attack on the Holy Roman Empire and the house of Austria. In 1670 Pufendorf was called to the University of Lund, where he published in 1672 the *De jure naturae et gentium, libri octo*, and in 1675 a résumé of it as *De officio hominis et civis*.

In the *De jure naturae et gentium* Pufendorf took up in great measure the theories of Grotius and sought to complete them by means of the doctrines of Hobbes and of his own ideas. His first important point was that natural law does not extend beyond the limits of this life and that it confines itself to regulating external acts. He combated Hobbes's conception of the state of nature and concluded that the state of nature is not one of war but of peace. But this peace is feeble and insecure, and if something else does not come to its aid it can do very little for the preservation of mankind. As regards public law Pufendorf, while recognizing in the state (*civitas*) a moral person (*persona moralis*), teaches that the will of the state is but the sum of the individual wills that constitute it, thus showing himself a precursor of J. J. Rousseau and of the *Contrat social*. Pufendorf powerfully defends the idea that international law is not restricted to Christendom, but constitutes a common bond between all nations.

In 1677 Pufendorf was called to Stockholm as historiographer-royal. To this new period belong *Einleitung zur Historie der vornehmsten Reiche und Staaten*, also the *Commentarium de rebus suecicis*, and *De rebus a Carolo Gustavo gestis*. In his *De habitu religionis christianae ad vitam civilem* he traces the limits between ecclesiastical and civil power. This work propounded for the first time the so-called "collegial" theory of church government (*Kollegialsystem*), which, developed later by Pfaff (1686–1760), was the basis of the relations of church and state in Germany.

This theory makes a fundamental distinction between the supreme jurisdiction in ecclesiastical matters (*Kirchenhoheit* or *jus circa sacra*), which it conceives as inherent in the power of the state in respect of every religious communion, and the ecclesiastical power (*Kirchengewalt* or *jus in sacra*) inherent in the church, but in some cases vested in the state by tacit or expressed consent of the ecclesiastical body. The theory helped towards the principle of toleration.

It was put into practice to a certain extent in Prussia in the 18th century. The theory, of course, has found no acceptance in the Roman Catholic Church, but it none the less made it possible for the Protestant governments to make a working compromise with Rome.

In 1688 Pufendorf took service under Frederick William, elector of Brandenburg, but he had no sooner arrived than the elector died. His son, Frederick III, fulfilled the promises of his father; and Pufendorf, historiographer and privy councillor, was instructed to write a history of the Elector Frederick William (*De rebus gestis Frederici Wilhelmi Magni*). Pufendorf was also created baron.

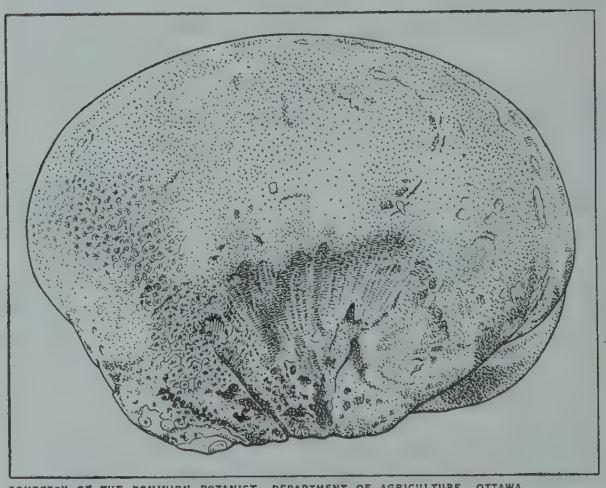
Pufendorf died at Berlin on Oct. 26, 1694.

The value of Pufendorf's work was much underestimated by posterity. Much of the responsibility for this injustice rested with Leibnitz, who would never recognize the incontestable greatness of one who was constantly his adversary, and whom he dismissed as "vir parum jurisconsultus et minime philosophus." His *Jurisprudence* is the standard one for the 17th and 18th centuries.

Bluntschli, in *Deutsches Staats-Wörterbuch* (1857–70), and *Geschichte des allgemeinen Staatsrechts und der Politik* (1864); J. Lorimer, *The Institutes of the Law of Nations* (2 vols., 1883–84); J. C. Droysen, "Zur Kritik Pufendorfs" in his *Abhandlungen zur neueren Geschichte* (1876); W. Roscher, *Geschichte der National Oekonomik in Deutschland* (1892); O. Franklin, *Das deutsche Reich nach Severino von Monzambano* (1874).

PUFF ADDER: *see* ADDER; VIPERS; SNAKES.

PUFF-BALL, the popular name of a group of fungi belonging to the Basidiomycetes (*see* FUNGI), and so called because of the cloud of brown dust-like spores which is emitted when the mature plant bursts or is struck a blow. They are common in meadows and woods and on heaths or lawns, and when young



COURTESY OF THE DOMINION BOTANIST, DEPARTMENT OF AGRICULTURE, OTTAWA

Puff-ball. A medium sized specimen of the giant puff-ball (approximately 8½ in. wide)

resemble white balls, sometimes with a short stalk, and are fleshy in texture. While white and fleshy they are edible.

The giant puff-ball, *Calvatia maxima*, may sometimes attain a weight of 15 pounds or more and measure up to 4 to 5 ft. or more in circumference. It has been estimated that a specimen measuring 15.7 x 11.0 x 7.8 in. will produce approximately 7,000,000,000,000 spores.

PUFF-BIRD, the name given to a group of birds forming the family *Bucconidae*, of the order Piciformes, which also includes the woodpeckers (*q.v.*). The *Bucconidae* are confined to the neotropical region, in the middle parts of which, and especially in its sub-Andean subregion, they are, as regards species, abundant; while only two seem to reach Guatemala and but one Paraguay. *Chelidoptera* breeds in holes in banks, and lays white eggs. The *Bucconidae* are plainly coloured, and the majority have a spotted or mottled plumage suggestive of immaturity.

PUFFIN, a sea-bird (*Fratercula arctica*), known also as bottle-nose, coulterneb, pope, sea-parrot and tammy-norie. Of old time, puffins were a valuable commodity to the owners of their breeding-places, for the young were taken from the holes in which they were hatched, and were "kept salted and reputed for fish." Puffins resort in vast numbers to certain stations on the coast, reaching them in spring with remarkable punctuality. They lay their single egg (white, with a few grey markings at first, but which speedily becomes begrimed by the soil) in a shallow burrow, which they either dig for themselves or appropriate from a rabbit.

The plumage of both sexes is glossy black above—the cheeks grey, encircled by a black band—and white beneath; the feet are of a bright reddish orange. The most remarkable feature of these birds is their huge bill. In the breeding season this is very deep, laterally flattened, parti-coloured—blue, yellow and red—and curiously grooved and embossed in places. The puffin's bill undergoes an annual moult, some of its most remarkable appendages, dropping off at the end of the breeding season. The puffin, when feeding its young, manages to arrange crosswise in its bill, a number of fish at a time. In the north Pacific we find the horned (*F. corniculata*) and the crested puffin (*Lunda cirrhata*).

PUGACHEV, EMEL'YAN IVANOVICH (1741?–1775), Russian pretender, the date of whose birth is uncertain, was the son of a small Cossack landowner. He married a Cossack girl Sofia Nedyuzheva, in 1758, and the same year was sent with his fellow Cossacks to Prussia, under the lead of Count Zachary Chernuishev. In the first Turkish War (1769–74) of Catherine II. Pugachev, now a Cossack ensign, served under Count Peter Panin and was present at the siege of Bender. Invalided home, he led for the next few years a wandering life; was more than once arrested and imprisoned as a deserter; and finally, after frequenting the monasteries of the "Old Believers," who exercised considerable influence over him, suddenly proclaimed himself (1773) to be Peter III. Pugachev asserted that he and his friends had escaped from Catherine, and were resolved to redress grievances, give liberty to the Cossacks and put Catherine in a monastery. He held a mimic court at which one Cossack impersonated Nikita Panin, another Zachary Chernuishev and so on. At the beginning of Oct. 1773 500 roubles was considered a sufficient reward for the head of the troublesome Cossack. At the end of November 28,000 roubles were promised. Still, Catherine, in her correspondence with Voltaire, affected to treat *"l'affaire du Marquis de Pugachev"* as a mere joke. By the beginning of 1774 the forts on the Volga and Ural were in the hands of the rebels; the Bashkirs had joined them; and the governor of Moscow reported great restlessness in central Russia. Pugachev captured Kazan, reduced most of the churches and monasteries there to ashes and massacred those who refused to join him. Panin, the conqueror of Bender, was sent against the rebels with a large army, but the innumerable and ubiquitous bands of Pugachev were victorious in nearly every engagement. Not till August 1774 did General Mikhelson inflict a crushing defeat upon the rebels near Tsaritsyn, when they lost ten thousand in killed and prisoners. Suvorov completed their discomfiture. Pugachev was delivered up by his own Cossacks on attempting to fly to the Urals (Sept. 14), and was brought in an iron cage to Moscow, where he was executed on Jan. 11, 1775.

See N. Dubrovin, *Pugachev and his Associates* (Rus.; Petersburg, 1884); *Catherine II., Political Correspondence* (Rus. Fr. Ger.; Petersburg, 1885, etc.); S. I. Gnyedich, *Emilian Pugachev* (Rus.; Petersburg, 1902); also the literature quoted *s.v.* CATHERINE II.

PUGACHEVSK (formerly NIKOLAYEVSK), a Russian town in the Samara province, in 52° 1′ N., 48° 48′ E., on the Irgiz river. Population 17,460. It is a collecting point for agricultural produce. Under the name of Mechetnoye, Nikolayevsk was founded in 1762 by the Old Believers who had fled to Poland and returned when Catherine II undertook to grant them religious freedom. In 1828 serious persecutions began, with the result that the monasteries were closed with the exception of three, which were handed over in 1829 and 1836 to the United Greek Church. In 1835 the name of the town was changed to Nikolayevsk.

PUGET, PIERRE (1622–1694), French painter, sculptor, architect and engineer, was born at Marseille, on Oct. 31, 1622. He travelled in Italy as a young man, and was employed by Pietro di Cortona on the ceilings of the Barberini palace. On his return to Marseille in 1643, he painted portraits and carved the colossal figure-heads of men-of-war; he also painted numerous pictures for Aix, Toulon, Cuers and La Ciotat; his caryatides for the hôtel de ville of Toulon were executed between 1655 and 1657. Fouquet employed him to sculpture a "Hercules" for his château in Vaux. In 1655, owing to a serious illness, he was forced to give up painting. In 1660 he was in Genoa, where he executed his French Hercules (Louvre) and the statues of St. Sebastian and of Alexandre Sauli in the church of Carignano (*c.* 1664). In 1669, at the summons of Colbert, he returned to France, and took up his old work in the dockyards of Toulon, until in 1685, disheartened by the destruction by fire of an arsenal he was constructing, he returned to Marseille. Here he continued the series of sculptures on which he had been employed by Colbert. His statues of Milo (1682), Perseus and Andromeda (1684), and the bas-relief, Alexander and Diogenes (1685) are in the Louvre. In 1688 he visited Paris, but court intrigues obliged him to abandon the project of an equestrian statue of Louis XIV., and he retired to Marseille, where he died on Dec. 2, 1694. His best work, the St. Sebastian at Genoa, shows energy and life. In the museum of Aix in Provence is the bust of a long-haired young man, believed to be Louis XIV., made by Puget in 1660.

See L. Lagrange, *Pierre Puget* (1868, with a catalogue of works); C. Ginoux, *Annales de la vie de P. Puget* (1894); P. Auquier, *Pierre Puget . . . biographie critique* (1903).

PUGILISM, the practice or sport of fighting with the fists (from Lat. *pugil,* boxer, Gr. *πύξ,* with clenched fist). The first mention of such fighting in literature is found in the 23rd book of the *Iliad;* another full description is in Virgil, *Aeneid.*

Although fist-fighting was supposed by the Greeks of the classic period to have been a feature of the mythological games at Olympia, it was not actually introduced into the historic Olympic contests until the 23rd Olympiad after the re-establishment of the famous games by Iphitus about 880 B.C. Onomastos was the first Olympic victor. Wearing no belt, or *ζῶμα,* the contestants, except for the cestus, fought entirely naked, since the custom had been introduced in the 15th Olympiad, and was copied by the contestants at the Pythian, Nemean, Isthmian and Panathenaic games (*see* GAMES, CLASSICAL). At Olympia the boxers were rubbed with oil to make them supple and limit the flow of perspiration, a precaution the more necessary as the Olympic games were held during the hottest part of the year. The cesti, of which there were several varieties, were bound on the boxers' hands and wrists by attendants or teachers acting as seconds. On account of the weight of the gloves worn, the style of boxing differed from that now in vogue (*see* BOXING), the modern straight-from-the-shoulder blow having been little used. Both Homer and Virgil speak of "falling blows," and this was the common method of attack, consisting more in swinging and hammering than in punching. The statue of a Greek boxer in the Louvre shows the right foot forward, the left hand raised as if to ward off a blow from above, and the right hand held opposite the breast, the whole attitude more resembling that of a warrior than of a modern boxer. The Greek champions trained for months before the games, but encounters between athletes armed with such terrible weapons as the loaded cestus were bound to result in very serious bruises and even disfigurement. Pluck was as highly thought of as at the present day, and it was related of a certain Eurydamas, that, when his teeth were battered in, he swallowed them rather than show that he was hurt, whereupon his antagonist, in despair at seeing his most furious blows devoid of effect, gave up the battle. As, on account of the swinging style of blows, the ears were particularly liable to injury ear-protectors (*ἀμφωτίδες*) were generally used in practice, though not in serious combats. The so-called "pancratist's ear," swollen and mis-shapen, was a characteristic feature of the Greek boxer.

The rules of Greek boxing were strict. No wrestling, grappling, kicking nor biting were allowed, and the contest ended when one combatant owned himself beaten. On this account pugilism and the *pancratium* (*see* pp. 758) were forbidden by Lycurgus, lest the Spartans should become accustomed to an acknowledgment of

defeat (Plutarch, *Lycurgus*). Moreover, it was strictly forbidden to kill an adversary, on pain of losing the prize. Rhodes, Aegina, Arcadia and Elis produced most of the Olympic victors in boxing, which was considered an excellent training for war.

The Greek athletic contest called *pancratium* (παγκράτιον, complete or all-in, contest), which was introduced into the Olympic games in the 38th Olympiad, was a combination of boxing and wrestling in which the contestants, who fought naked, not wearing even the cestus, were allowed to employ any means except biting to wring from each other the acknowledgment of defeat. Boxing, wrestling, kicking, dislocation of joints, breaking of bones, pulling of hair and strangling were freely indulged in. The fight began with sparring for openings and was continued on the ground when the contestants bit the dust. Sudden attacks were also taught, reminding one of the Japanese *jiu-jitsu*. The *pancratium* was considered by the Greeks the greatest of all athletic contests. It became popular in Rome during the empire and remained so until the time of Justinian. Diagoras of Rhodes, his three sons and many grandsons, who were sung by Pindar (*Olymp.* 7), were the most celebrated of the Olympic boxing champions. A celebrated fighter and wrestler was Milo of Crotona (520 B.C.).

Boxing was evidently in vogue in very ancient times in Italy, imported, in all probability, from Greece, for Livy (i. 35) relates that, at the first celebration of the great Roman games (*ludi, Romani magnique varie appellati*) by Tarquinius Priscus (6th century B.C.), boxers were brought from outlying provinces; and there was an old tradition that a school of pugilism flourished in Etruria in heroic times. During the republic boxing was cultivated as a gentlemanly exercise, and we find Cato the Elder giving his son instruction in the art (Plutarch, *Cato Major*). Tacitus (*Ann.* xvi. 3) says that the emperor Caligula imported the best Campanian and African pugilists for the gladiatorial games, and Strabo (iii. 3) records that the Lusitanians and also the Indians, who gave virgins as prizes, boxed. The art remained popular in Italy down to a late period of the empire.

Pugilism in England.—From the fall of the Roman empire to the beginning of the 19th century pugilism seems to have been unknown among civilized nations with the single exception of the English. The first references to boxing in England as a sport occur towards the end of the 17th century, but little mention is made of it before the time of George I., when "prize-fighters" engaged in public encounters for money, with the backsword, falchion, foil, quarter-staff and single-stick, and, to a less extent, with bare fists, the last gradually gaining in popularity with the decline of fencing. The most celebrated of these fighters and the one who is generally considered to have been the first champion of England, fighting with the bare fists, was James Figg, who was supreme from 1719 to 1730. Figg was succeeded by Pipes and Gretting, both of whom made way in 1734 for Jack Broughton, who built the amphitheatre for public displays near Tottenham Court road and who was undisputed champion until 1750. Broughton seems to have been a man of intelligence, and to him is ascribed the scientific development of the art of boxing. During his time the sport became truly national and the prize-fighter the companion of the greatest in the land. Among Broughton's successors were Slack, "Big Ben" Brain, Daniel Mendoza (a Jew who flourished about 1790 and was the proprietor of the Lyceum in the Strand), J. Jackson, Tom Cribb, Jem Belcher, Pearce (called the "Game Chicken"), and John Gully, who afterwards represented Pontefract in parliament.

To Broughton is ascribed the invention of boxing-gloves for use in practice. All prize-fights, however, took place with bare knuckles in roped-off spaces called rings, usually in the open air. Pugilists toughened their hands by "pickling" them in a powerful astringent solution. A fight ended when one of the "bruisers," as they were called, was unable to "come to the scratch," *i.e.*, the middle of the ring, at the call of the referee at the beginning of a new round. Each round ended when one fighter fell or was knocked or thrown to the ground, but a pugilist "going down to avoid punishment," *i.e.*, without being struck by the opponent, was liable to forfeit the fight. Wrestling played an important rôle in the old prize-ring, and a favourite method of weakening an adversary was to throw him heavily and then fall upon him, seemingly by accident, as the manoeuvre, if done intentionally, was foul. The fighting was of the roughest description, low tricks of all kinds being practised when the referee's attention was diverted, gouging out an adversary's eye being by no means unknown. Until 1795 pugilists wore long hair, but during a fight in that year Jackson caught Mendoza by his long locks and held him down helpless while he hit him. This was adjudged fair by the referee, with the result that prize-fighters have ever since cropped their heads. Nevertheless, there were rules which no fighter dared to overstep, such as those against kicking, hitting below the belt, and striking a man when he had fallen.

From the time of Cribb the English champions were Tom Spring (1824), Jem Ward (1825), Jem Burke (1833), W. Thompson, called "Bendigo" (1839–45), Ben Caunt (1841), W. Perry the "Tipton Slasher" (1850), Harry Broome (1851), Tom Sayers (1857–60), Jem Mace (1861–63), Tom King (1863), and again Mace, until 1872. In America boxing began to be popular about the beginning of the 19th century. The first recognized national champion was Tom Hyer (1841–48), who was followed by James Ambrose (born in Ireland), called "Yankee Sullivan"; John Morrissey (afterwards elected to the United States Congress); John C. Heenan; Tom Allen (of England); Jem Mace (of England); J. Kilrain; John L. Sullivan (1880–91). Sullivan was the last of these to fight with the bare fists. Pugilism (*i.e.*, fighting with the bare fists) was driven out in favour of boxing (*i.e.*, fighting with the glove) by public opinion and by the general adoption after 1866 of the Marquis of Queensberry rules. The last championship fight under the old prize ring rules was fought between Frank Slavin and Jem Smith in Belgium, the latter retaining the championship. The old prize ring being illegal and extinct no champion can succeed him. *See* BOXING.

See Egan, *Boxiana* (1818–1824); *Fistiana* (1868); *American Fistiana* (1876).

PUGIN, AUGUSTUS WELBY NORTHMORE (1812–1852), English architect, son of Augustus Charles Pugin (1762–1832), a Frenchman who settled in London as an architectural draughtsman, was born in Store Street, Bedford Square, on Mar. 1, 1812, and died on Sept. 14, 1852, at Ramsgate. He was educated at Christ's Hospital and in his father's office, where he helped to prepare a large series of works on the Gothic buildings of England. All through his life he made numerous drawings and sketches, in pen and ink or with sepia monochrome, perfect in their delicacy and precision of touch. After his reception into the Roman Catholic Church in 1833, he became a leader in the English Gothic revival. In 1837–43 he assisted Sir Charles Barry by working out the details of the designs for the new Houses of Parliament at Westminster; and though his exact share was the subject of bitter controversy after both he and Barry were dead, there is no doubt that the excellence of the details was partly due to him and to his training of the masons and carvers. Many of his executed works suffered from the fact that his designs were altered, both by cutting down their proportions and by introducing shams, such as plaster groining and even cast-iron carving. The cathedral of St. George at Southwark, and the church in Farm Street, Berkeley Square, London, are melancholy instances of this. The cathedral of Killarney and the chapel of the Benedictine monastery of Douai best express the original conception. Pugin was very broad in his love for the mediaeval styles, but on the whole preferred the Perpendicular of the 15th century as being best suited to modern requirements. He used this with success in his own house at Ramsgate and in the stately Adare Hall in Ireland built for Lord Dunraven.

In 1836 Pugin published his *Contrasts; or a Parallel between the Architecture of the 15th and 19th centuries; True Principles of Christian Architecture* (1841); *Glossary of Ecclesiastical Ornament* (1844); and *Treatise on Chancel Screens and Rood Lofts* (1851). He was a skilful etcher.

See B. Ferrez, *Recollections of A. W. Pugin and his Father* (1861); Paul Waterhouse, "The Life and Work of Welby Pugin" in the *Architectural Review*, iii., iv. (1898).

PUINAVIAN, a tribe of South American Indians, which appear to constitute by itself alone an independent linguistic

stock. The Puinavis live or lived on the border between Venezuela and Colombia, on the Inirida river, just south of 4° N. lat. *See* A. F. Chamberlain, *Sur quelques familles linguistiques . . . de l'Amérique du Sud* (J. Soc. Americanistes de Paris [n.s.], vol. vii., pp. 179–202).

PUISNE, a term in law meaning "inferior in rank." It is pronounced "puny" and the word, so spelt, has become an ordinary adjective meaning undersized. By the Supreme Court of Judicature act, 1877, a "puisne judge" is defined as a judge of the High Court other than the lord chancellor, the lord chief justice of England, the master of the rolls, the lord chief justice of the common pleas, and the lord chief baron, and their successors respectively; but the last two offices have since been abolished.

PUJA, Hindu "worship": whence *pujāri,* "priest." Colloquially the word is used for any rite; and "pujah of the flag" is the sepoy term for trooping the colours.

PUKET, sometimes spelled BHUKET (the Chinese name is *Tongkah*), leading Thai port on the west coast of the Malay peninsula, on Junk Ceylon island (also called Puket) in 7° 50′ N. and 98° 24′ E. The island constitutes one of the 70 changvads (districts) of Thailand; pop. (1937) 41,827, nearly half Chinese. Rich tin deposits have been worked by Chinese from ancient times. A European company commenced modern dredging operations in 1907. The 1938–39 tin ore production was 4,256 tons. Exports of ore from the Puket customs area (the Thai west coast) amounted to 31,873,287 bhat (about $14,000,000) in 1939–40. Rubber stood second among exports, followed by betel-nuts, oriental equivalent of chewing tobacco. European merchants began trading at Puket in the 16th century. It was besieged by the Burmese during the 18th century wars between Burma and Thailand, but was relieved by troops from the mainland.

PULASKI, CASIMIR, COUNT (1748–1779), Polish soldier, was born in Podolia in 1748, and took a prominent share, under his father Count Joseph Pulaski, in the formation of the confederation of Bar and in the military operations which followed, becoming ultimately commander-in-chief of the Polish patriot forces. Driven into exile about 1772, Pulaski went to America and joined the army of Washington in 1777. He distinguished himself at Brandywine, was made a brigadier-general and chief of cavalry by Congress, and fought at Germantown, and in the battles of the winter 1777–78, after which he raised a mixed corps called the Pulaski legion, with which he defended Charleston in May 1779. He was mortally wounded at Savannah, dying on Oct. 11th.

PULASKI, a town of Virginia, U.S.A., county seat of Pulaski Co.; 50 mi. S.W. of Roanoke, on federal highway 11 and Norfolk and Western Ry. Pop. (1950) 9,136. It is in a region of beautiful scenery and of coal, lead and iron mines, between the Blue Ridge and Allegheny mountains. It is a summer resort.

PULCI, LUIGI (1432–1484?), Italian poet, was born at Florence on Dec. 3, 1432, of a well-connected family. His elder brother Luca (d. 1470) was also a poet, and the share of each of the two brothers in the poems *Pistole, Driadeo d'amore,* and *Ciriffo Calvaneo* is not easily distinguishable. Luigi was patronized by Cosimo, Piero, and Lorenzo de' Medici. He used to find an object for his mockery in the long romances of chivalry recited in the streets and in public places. He chose for his semi-burlesque poem, *Morgante,* generally known as *Morgante Maggiore* (complete ed. Venice 1482; critical ed. Milan 1875), the epic of Charlemagne. The story centres in Ganelon's hatred of Roland and the Christian Paladins. Pulci's *Letters* were edited at Lucca 1886.

See L. Einstein: *L. Pulchi and the Morgante Maggiore* (Berlin 1902) A. Momigliano: *L'Indole e il Riso di Pulci* (1907); E. Walser: "Die Religion des L. Pulci" in *Die Neueren Sprachen* 10 Beiheft (1926).

PULICAT, a town of British India, in Chingleput district, Madras, 25 m. N. of Madras city. Pop. (1941), 3,781. The Dutch built a fort here as early as 1609, and it was for a long time their chief settlement on the Coromandel coast. Repeatedly captured, it did not finally become British until 1825. It gives its name to the Pulicat lake, a shallow lagoon stretching for about 37 m. along the coast. The seaward side is formed by the island of Sriharikota, which supplies firewood to Madras city.

PULITZER, JOSEPH (1847–1911), American editor and newspaper proprietor, was born in Mako, Hungary, April 10, 1847. His father, a grain-merchant, was Magyar-Jewish; his mother Austro-German. Pulitzer was educated privately in Budapest. Excluded from the army as a result of physical defects, and failing in an attempt to join the French Foreign Legion, he was induced by an American agent to emigrate to the United States as a prospective recruit for the Union army. He enrolled in Company L, 1st New York Lincoln cavalry, for a term of one year. Discharged on July 7, 1865, in New York city, he looked in vain for work there. In the autumn he started west for St. Louis, where he arrived penniless.

In St. Louis, with its large German population, Pulitzer's progress was rapid. While making his living by odd employments, he studied for the bar and was admitted in 1867. On March 6 he was naturalized, and in 1868 became a reporter on the *Westliche-Post* staff; in Dec. 1869 he was elected to the lower house of the legislature. Here he led a successful movement to reform the corrupt county government of St. Louis. When the revolt against Grant led to the Liberal Republican movement in 1871–72, Pulitzer helped to organize this party in Missouri and was one of the secretaries of the Cincinnati convention which nominated Greeley.

Pulitzer then became a newspaper proprietor. Some owners of the *Westliche-Post* sold him a share on liberal terms. This he soon resold for $30,000, using part of the proceeds for an extended tour of Europe. On his return he purchased a moribund German daily, the St. Louis *Staats-Zeitung,* for a song, and sold its Associated Press franchise to the *Globe* for $20,000. In 1876 he took an active share in the presidential campaign, breaking loose from all his Republican associates.

On June 19, 1878, he married Miss Kate Davis, a distant relative of Jefferson Davis. On Dec. 9 of the same year he laid the foundation of his fortune by purchasing at auction the worn-out St. Louis *Dispatch,* paying $2,500 cash and giving a $30,000 lien. This newspaper he merged with the *Post,* owned by John A. Dillon, as the *Post-Dispatch,* which immediately began to pay and soon dominated the St. Louis evening field. It was independent in politics and devoted to "hard money" and tariff reform. In 1880 Pulitzer became sole owner. He laboured with unremitting energy, and the profits were soon running from $40,000 to $85,000 a year. Unfortunately in Oct. 1882 his chief editorial aid, Col. John A. Cockerill, shot and killed a lawyer, Col. Alonzo W. Slayback, in a bitter quarrel of political origin. The case did not come before the courts, but public reprobation was so great that the *Post-Dispatch* lost revenue and Pulitzer thereafter felt unwelcome in St. Louis. He departed for the East in the spring of 1883, and bought the New York *World* for $346,000, taking possession on May 10.

In 1884 he was elected to Congress from the Ninth District, a position he resigned before his term expired. Under its new management the *World* won an immediate prosperity. It was aided by a quarrel in which its rival, the *Herald,* became engaged with the newsdealers, and by the *Sun's* disastrous decision in 1884 to support Benjamin F. Butler for the presidency. By 1886 the annual earnings of the *World* were more than $500,000. With these resources Pulitzer in 1887 established the *Evening World,* which lost $100,000 the first year, but by 1890 was highly profitable. William R. Hearst's purchase of the New York *Journal* in 1895 brought the *World* a powerful competitor, and it met the challenge on Feb. 10, 1896, by reducing its price from two cents to one. The daily circulation of the *World* quickly rose to 300,000 and its Sunday circulation before the end of 1896 reached 623,000 copies. To the *World,* as to the *Post-Dispatch,* Pulitzer gave a tone of aggressive editorial independence. The paper earnestly supported Cleveland in his contests for the presidency in 1884, 1888 and 1892. It was sympathetic to labour, and in 1892 took the side of the striking steel workers at Homestead, Pennsylvania. It opposed Bryan for the presidency in 1896. A year later the *World* became an advocate of war with Spain, for Pulitzer sympathized with the Cuban struggle for liberty. Meanwhile Pulitzer's health, including his eyesight, compelled him to

live the secluded existence of an invalid, but he kept in intimate touch with the *World* until within a few weeks of his death in Charleston (S.C.), Oct. 29, 1911.

During his lifetime Pulitzer had given liberally. In 1903 he endowed the School of Journalism of Columbia university, opened in 1912. In his will he established a series of prizes, known as the Pulitzer prizes, to be awarded annually, for letters, the drama, music and newspaper work.

PULKOVO (Pulkowa), the most important meteorological observatory in Russia, 10 m. S. of Leningrad in 59° 47′ N., 30° 18′ E., altitude 248 ft. and built 1833–9. Russian longitude is usually indicated from Pulkovo, though some recent Russian atlases and maps give longitude east of Greenwich, the difference having been fixed by wireless.

War conditions (1914–21) made a considerable break in international exchanges with Pulkovo. Yudenich captured Pulkovo in his march against Leningrad in 1919, and its re-capture by Soviet troops was the beginning of the collapse of his army.

PULLEY, a wheel, either fixed to a turning axle or carried freely on a stationary one, the periphery of which is adapted to receive some form of wrapping connector. A pulley carried on a rotating shaft and connected to another pulley on a second shaft by an endless band consisting of a flat belt, rope, chain or similar connector serves for the transmission of power from the one shaft to the other and is known as a driving pulley; while combinations of pulleys or "sheaves" mounted in fixed or movable frames or "blocks" facilitate the raising of heavy weights.

Driving Pulleys.—These are usually constructed of cast iron, and are of circular form, having a central nave by which they are secured to the shaft by keys or other fastenings, and straight or curved arms connecting the nave to the rim, which latter is of a form adapted to the connector. Pulleys are usually cast in one piece, and the proportions of the various parts are designed to resist the unknown stresses due to contraction of the casting in cooling. The rim is slightly wider than the belt, and is of such a section as will suffice to resist the stress due to the pull of the belt, which is commonly taken as 80lb. per inch of width for single belting and 140lb. per inch of width for double belting. The rim is also subject to a centrifugal tension of amount wv^2/g pounds per square inch of section, where w is the weight in pounds of a length of one foot of the pulley rim one square inch in section, and v is the velocity of the rim in feet per second. This stress amounts to 1,043lb. per square inch, if the velocity is 100 ft. per second. The combination of these stresses generally limits the rim velocity of cast-iron pulleys to 80 or 100ft. per second. The arms, preferably straight, are elliptical in cross-section, diminishing from the nave to the rim, and are usually designed as equally loaded cantilevers, fixed at the nave and free at the rim. The statical experiments of C. H. Benjamin (*American Machinist,* 1898) showed that the rim is usually not sufficiently rigid to load the arms equally, and that the ends of the arms are subjected to bending movements of opposite sign, that at the nave being almost invariably the greater.

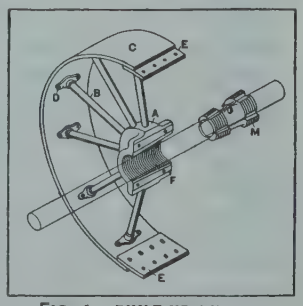

FIG. 1.—BUILT-UP PULLEY

Pulleys are also built up of wrought iron and steel, and can then be constructed entirely free from internal stress; they are thus much lighter and stronger, and are not liable to fly to pieces like cast iron if they break. Fig. 1 shows a built-up pulley having a cast-iron nave A, straight wrought-iron arms B, screwed therein and connected to a steel plate-rim C by riveted ends, and also by screwed flanges D riveted on each side to the rim. The pulley is in halves to facilitate fixing, and when in place the sections C are joined by plates E bolted or riveted to the rim. The two halves of the nave are secured by bolts or rivets passing through the flanges F, and the pulley is connected to the shaft by a sunk key or by conical keys driven in between the shaft and the boss, which latter is bored to suit. A modified form of this arrangement of cone keys is shown in the figure, in which a screwed conical bush M, divided into several parts longitudinally, is clamped round the shaft, and screwed into the corresponding part of the nave until the grip is sufficient. The parts of the bush are glued to a sheet of emery paper, so that its rough side may give a better grip on the shaft.

Pulleys are also made of paper, wood and other materials. Wooden pulleys are preferably made of maple, the rim being formed of small sections morticed, pinned and glued together, with the grain set in such directions that any warping of the material will leave the cylindrical form practically unaltered. Wooden pulleys are generally made in two halves, bolted together at the rim and nave, and are provided with wooden spokes dovetailed into the rim and secured by keys.

If the centre of gravity of a pulley is on the axis of rotation, and the whole mass is distributed so that the axis of inertia coincides with the axis of rotation, there can be no unbalanced force or unbalanced couple as the pulley revolves. The magnitude of the unbalanced force, for a mass of w pounds at a radius of r feet and a velocity of v feet per second, is expressed by wv^2/gr lb.; and, since the force varies as the square of the velocity, it is necessary carefully to balance a pulley running at a high speed to prevent injurious vibrations. This can be accomplished by attaching balance-weights to the pulley until it will remain stationary in all positions, when its shaft rests on two horizontal knife-edges in the same horizontal plane, or, preferably, the pulley and shaft may be supported on bearings resting on springs, and balanced by attached masses until there is no perceptible vibration of the springs at the highest speed of rotation.

The rims of pulleys, round which flat bands are wrapped, may be truly cylindrical, in which case the belt will run indifferently at any part of the pulley, or the rim may be swelled towards the centre, when the central line of the band will tend to run in the diametral plane of the pulley. This self-guiding property may be explained by the tendency which a flat band has, when running upon a conical pulley in a direction normal to its axis, to describe a spiral path as it wraps on to the surface because of the lateral stiffness of the material; the advancing side therefore tends to rise towards the highest part of the cone. In practice the pulley rim is curved to a radius of from three to five times its breadth.

Parallel Shafts.—Parallel shafts may be driven by flexible bands or connectors passing over pulleys, the central planes of which coincide, without any guiding arrangements for the belting. The shafts revolve in the same or opposite directions, according as the belt is open or crossed. Means of changing the relative speeds of rotation are furnished by pulleys of continuously varying diameter, or by speed cones. A common arrangement for driving a lathe spindle, in either direction at several definite speeds, is to provide a countershaft on which are mounted two fixed pulleys and two loose pulleys to accommodate two driving belts from the main shaft, one of which is open and the other crossed. The belts are moved laterally by the forks of a striking gear pressing on the advancing sides of the belts, and the pulleys are arranged so that the belts either wrap round the loose pulleys, or can be shifted so that one wraps round a fixed pulley, while the other still remains on its loose pulley. Motion in either direction is thereby obtained and a considerable variation in the speed of rotation can be obtained by providing a cone pulley on the countershaft, which drives the cone pulley secured to the lathe spindle by a separate band. The dimensions of the pulleys are generally so arranged that the return motion of the lathe spindle is faster than the forward motion.

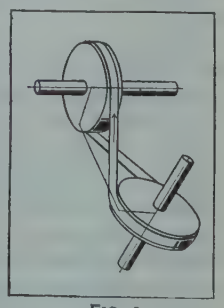

FIG. 2

When pulleys are mounted on shafts which are parallel to one another, the band will retain its position, provided that its central line advances towards each pulley in the diametral plane of this latter. This condition is fulfilled in the example shown by fig. 2, in which the central planes of each pulley pass through the points of delivery of the other pulley for the given direction of motion. If the motion is reversed the condition is no longer satisfied and the belt will leave the pulleys. In more complicated cases guide pulleys must be used. In the most general case for inclined pulleys, any two points may be chosen on the line of intersection of the diametral planes, and tangents drawn to the pitch circles of the pulleys. Guide pulleys are set with their diametrical planes in the planes containing corresponding pairs of tangents, and a continuous belt wrapped round these pulleys in due order can then be run in either direction.

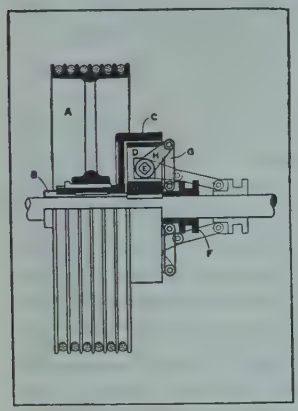

FIG. 3.—FRICTION CLUTCH FOR ROPE-PULLEY

The rims of pulleys for hemp or other ropes or cords are grooved, and the sides are usually either inclined at 45° or curved to give a sharper angle at the outside than at the bottom of the groove; in the latter case, as the rope wears it engages in a groove of greater angle and less effective grip. Wire ropes are injured by the lateral crushing of the material, and in this case the grooves are wide enough to allow the rope to rest on the rounded bottom, which is lined with leather or wood to diminish the wear and increase the friction. In English practice there are as many separate endless ropes as there are pairs of grooves in the two pulleys to be connected, but in cases of American practice the rope is continuously wound round the two pulleys, and the free end passes over a pulley mounted on a movable weighted carriage to adjust the tension.

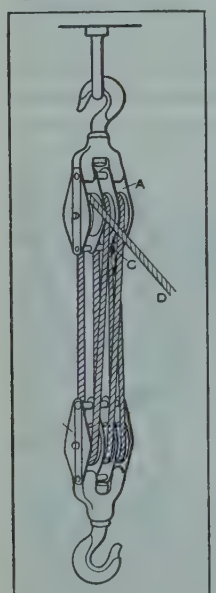

FIG. 4.—SHEAVE PULLEY BLOCK

Pulleys may be detachably connected to a shaft by friction clutches, so that they may be thrown in and out of engagement at will. The section, fig. 3, shows a clutch for a rope-driven pulley A, which runs freely on a bush B on the shaft, and is provided with an enlarged cylindrical nave or clutch box C. A split ring D, carried by the clutch and turning with it, can be thrust against the clutch box by right- and left-handed screws E, so that a sufficient grip is obtained to cause the clutch and the pulley to turn as one piece. The engagement of the pulley and clutch is determined by a hand-controlled block F sliding on the shaft, the movement of which is communicated to the right- and left-handed screw shafts by links G connected to the levers H.

Pulley Blocks.—Frames or blocks containing pulleys or sheaves are used in combination for lifting heavy weights. There are usually two blocks, of which one A (fig. 4) is fixed, and the other B is movable, and a rope or chain, with one end secured to one of the blocks at C, passes round the sheaves in a continuous coil, leaving a free end D at which the effort is applied. In the arrangement shown there are three equal sheaves in each block, and each set turns on a pin secured in the framing. The load, supported by the lower hook, is raised by hauling on the free end and, neglecting any slight obliquity of the plies of rope, the free end moves six times as fast as the lower block carrying the weight, and in the absence of friction and other resistances the mechanical advantage will be in the same ratio of the effort to the resistance. In practice the full advantage of this or any other similar combination is not realized, because of the friction of the sheaves against the pin or shaft, and more important still is the stiffness of the rope, which requires work to be done upon it to bend it round the sheave and straighten it again.

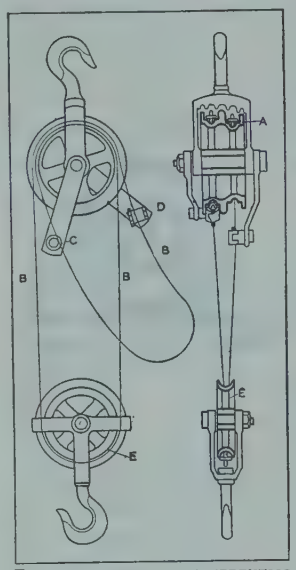

FIG. 5.—WESTON DIFFERENTIAL PULLEY BLOCK

Differential Pulley Block.—To obtain a greater ratio of resistance to effort, without using a large number of sheaves, various arrangements are used, of which the Weston differential pulley block is a typical example. The upper block carries a pair of chain pulleys A (fig. 5), strongly secured together and of slightly different effective diameters. An endless chain B, passing through guides C and D, encircles these pulleys and the single loose pulley E of the lower block, as indicated. If a greater difference of effort from resistance is required, a further mechanical advantage can be obtained by employing a separate hand-wheel and chain, or by forming the upper sheave with an annular spur-wheel gearing with a pinion driven by a hand-wheel and chain, as in the Tangye form of Weston pulley-block. The efficiency of the Weston pulley-block is less than 50%, and it does not therefore overhaul. An objection to this form of block is the great length of the endless chain, which may drag on the ground and pick up dirt and grit, and thereby interfere with the smooth working of the mechanism. Other forms, which do not require so lengthy a chain, sometimes employ an epicyclic train to obtain the reduced velocity of the load.

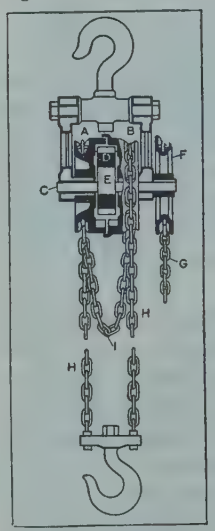

FIG. 6.—MOORE AND HEAD PULLEY BLOCK

The Moore and Head block has two equal chain-wheels A, B, fig. 6, loosely mounted on an axle C, and provided with annular toothed gear-wheels which usually differ by one tooth. A spur pinion D, gearing with both wheels, is carried loosely upon an eccentric E forming part of the central pin, so that when this latter is turned by the hand-wheel F and chain G the axis of the pinion describes a circle the diameter of which equals the throw of the eccentric, and a small relative motion of the two sheaves takes place, depending on the number of the teeth of the annular wheels. The motion obtained is divided between the two vertical parts of the chain H, which is wrapped round each sheave in opposite directions, with a free loop I between, while the ends are attached to the lifting hook. This form is self-sustaining at all loads.

Worm Gear Pulley.—To obtain a self-sustaining pulley tackle, which will have an efficiency of more than 50%, various arrangements are adopted, which during lifting automatically throw out of action a brake and cause it to come into action again when the effort is removed. A worm-gear tackle of this description is shown in fig. 7, in which a worm A, operated by a hand-wheel B and chain C, drives the worm-wheel D, thereby coiling up a chain E, one end F of which is secured to the upper

block, and the other end hangs loosely, after passing round the sprocket-wheel. The worm is of great pitch, so that if the effort were removed the weight would descend, did not the axial end thrust of the worm shaft throw into action a friction brake H, the resistance of which prevents motion downwards. In the brake shown, the cone I is pressed against a corresponding recess in the ratchet-wheel J, which latter turns loosely in the casing and is provided with a pawl not shown in the figure; this pawl allows freedom of motion when the load is being raised. The frictional grip between the two surfaces prevents return motion of the worm shaft and the load remains suspended, but it may be lowered by turning the hand-wheel so as to overcome the friction brake. Various other arrangements of friction brakes have been devised to give a resistance proportional to the load.

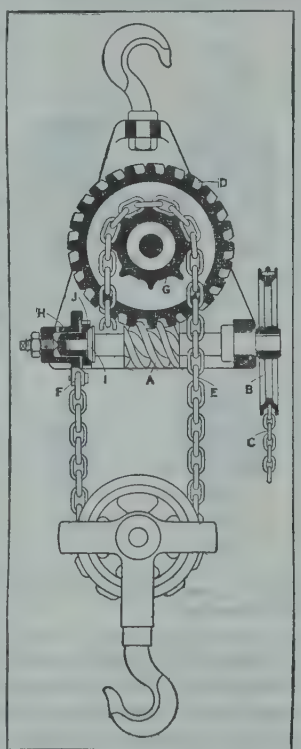

FIG. 7.—WORM-GEAR PULLEY BLOCK WITH AUTOMATIC BRAKE

Blocks, for lifting very heavy weights, are sometimes provided with an electric motor for driving the worm. The worm-wheel shaft then sometimes carries a spur-pinion gearing, with a spur-wheel on the lifting shaft, whereby a much greater advantage is obtained with a small loss by friction of the spur gearing.

PULLMAN, now a part of the city of Chicago. The place was founded in 1880 by George Mortimer Pullman (1831–97), the inventor of the Pullman sleeping car, and the founder (1867) of the Pullman Palace Car Company, who attempted to make it a "model town." Even the public works were the property of the Pullman Company and were managed as a business investment. Popular discontent with the conditions led to the annexation of Pullman to Chicago in 1889, but until 1910 the corporation held most of the property. In June and July 1894 a bitter railway strike developed in the Pullman works.

PULLMAN, a city of Whitman county, Washington, U.S., 75 mi. S. of Spokane, in the Palouse river valley, at an altitude of 2,750 ft. It is on federal highway 195, and is served by the Northern Pacific and the Union Pacific railways. Pop. (1950) 12,022. The State college of Washington (established 1890) is located there (college enrolment 5,100), the campus and experiment station occupying about 1,400 ac. Pullman was settled about 1884 and incorporated as a city in 1889.

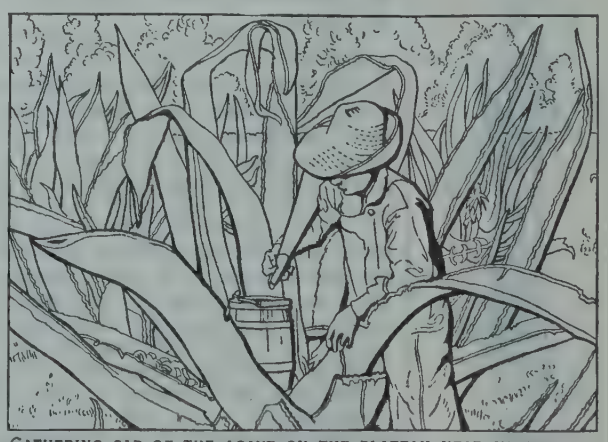
PULLMAN INCORPORATED (DELAWARE), a holding company formed in 1927, has three important subsidiaries: The Pullman Company (Chicago)—originally incorporated in 1867 as Pullman's Palace Car Company, with a capital of $100,000—is the largest operator of sleeping and other super-comfort railway cars in the world, controlling practically all the business in the United States and Mexico and part of that in Canada; Pullman-Standard Car Manufacturing Company (Chicago), the world's largest car building unit, and the Pullman-Standard Car Export Corporation (New York). At the beginning of 1940 The Pullman Company owned some 7,000 cars of which about 6,000 were sleeping cars. Over 200 of these were of the new light-weight and streamlined type. There were 750 parlour cars of different combinations, 143 composite cars, including baggage-club and other variations, and 15 private cars for special parties. In the year 1939, 15,655,135 revenue passengers were carried in Pullman cars, equal to a daily average of 42,890 in 5,100 cars. The passenger mileage was 8,485,399,123mi., or an average distance of 542 miles. Pullman-Standard Car Manufacturing Company in 1940 had 9 plants and 3 wheel foundries with these annual capacities: 2,370 passenger, 74,700 freight cars; 49,000 tons forgings, 287,500 wheels. Pullman-Standard Car Export Corporation's capacity is 1,500 freight and 150 passenger cars annually. (G. A. K.)

PULP: *see* PAPER MATERIALS.

PULPIT, a raised platform with enclosed front, whence sermons are delivered. Pulpits were probably derived from the *ambones* in the early Christian Church. (*See* AMBO.) There are many old pulpits of stone, though the majority are of wood. Those in churches are generally hexagonal or octagonal; and some stand on stone bases, and others on slender wooden stems, like columns. The designs vary according to the periods in which they were erected, having panelling, tracing, cuspings, crockets and other ornaments. Some are extremely rich, and ornamented with colour and gilding. A few also have rich canopies or sounding-boards. Their usual place is in the nave, mostly on the north side, against the second pier from the chancel arch. Out-door pulpits were common in the mediaeval period, and stood near a road or cross. Pulpits, for reading during the meals of the monks, are found in refectories.

Shortly after the Reformation the canons ordered pulpits to be erected in all churches. Many of the time of Elizabeth and James are beautifully carved, and are of Flemish workmanship. The pulpits in mosques, known as "mimbars," are canopied and approached by a straight flight of steps. These have a doorway at the foot, with an enriched lintel and boldly moulded head; the work is of wood, often inlaid, gorgeously painted and gilt.

PULQUE or **PULQUE FUERTE,** the national beverage of the Mexican natives. It is prepared by fermenting the juice of a number of species of the agave (*Agave americana,* etc.). The cultivation of the agave for purposes of pulque manufacture constitutes a considerable local industry. The juice of the agave termed *aguamiel* is allowed to ferment naturally for about ten days, and the product is termed *madre pulque.* A small quantity is added to fresh aguamiel, and a rapid fermentation is induced, the pulque being ready in a day or two. It has a heavy flavour, resembling sour milk, but it is esteemed by the natives because of its cooling and, according to them, nutritious properties.



GATHERING SAP OF THE AGAVE ON THE PLATEAU NEAR MEXICO CITY
In the making of pulque, the favourite drink of the Mexican people, the sap is sucked out of the plant into a tube, and from there poured into a pail or skin bag and allowed to ferment for about ten days

PULSE, throbbing or beating; in physiology the rhythmical beating due to the changes of blood tension in the arteries consequent on the expansion and contraction of their elastic tissues in response to the ejection of blood by the heart (*see* VASCULAR SYSTEM). In botany, a collective term for beans, peas, lentils

and other members of the family Leguminosae (*q.v.*).

PULSOMETER: *see* VACUUM.

PULTUSK, a town of Poland, on the Narew. Pop. (1946) 8,187. The town was entirely destroyed by fire in 1875, but was rebuilt on a more modern scale. In 1703 Charles XII of Sweden defeated and captured a Saxon army there, and in 1806 Napoleon defeated the Russians. The town was occupied by the Germans in 1915 and again in 1939. It was formerly part of the large estate of the bishops of Plock, whose former palace, dating from 1319, was destroyed in the fire.

PULVERIZED FUEL. The use of coal in the form of dust for raising steam has been known from isolated experiments for about the last forty years, but the fact that it was one of the most difficult methods of burning coal long delayed the development of the practice.

The theoretical advantages of burning crushed coal become obvious when one considers that if a cubic inch of coal, which has an exposed surface of six square inches, is crushed into cubes each of which has a side one-hundredth of an inch in length, the area of the exposed surface is multiplied one hundred times, and a more intimate mixing of the coal and air is rendered possible, and this without using a large excess of air. It is considered good practice under normal conditions with an average boiler furnace under conditions of mechanical stoking if 150 to 200 per cent of excess air is being admitted to the furnace. Under pulverized coal conditions of firing no difficulty is experienced in working regularly with not more than 20 to 30 per cent of excess air.

Inasmuch as coal-dust cannot be burnt in the ordinary way, special burners have to be provided. These differ in design, but the principles underlying all of them are the same. The coal is dried, pulverized, and the dust passing to the furnace is conveyed to a burner, mixed with air and burnt in the form of a jet. A point common to all the systems is that of the fineness to which it is necessary to reduce the coal. It has to be so fine that all of it will pass through a 100 mesh screen (that is to say a screen containing $100 \times 100 = 10{,}000$ apertures to the square inch) and 85 per cent of it through a 200 mesh screen.

There are a number of different forms of burners, the dust being driven into the fire-box by means of either fans or compressed air. In one system the air pressure is exerted in the tank, which is connected with the furnace by means of a pipe and the dust forced in a stream, unmixed with air, through the pipe to the furnace. In another it is drawn as required from the storage bin, mixed with air, and carried in suspension through pipes to the furnace at a high velocity. In yet another system the dust from the feed worm is blown into the fire-box.

Whilst the chief use of powdered fuel is in its application for raising steam, it is also largely used in cement works and in steel furnaces.

The economies claimed in respect of the use of coal in the powdered form over the lump coal are:—

(1) A reduction (by reason of the more complete combustion) in the amount of fuel necessary to secure a given heat result.

(2) Ability to use low-grade fuel.

(3) Saving in labour as stoking is rendered unnecessary.

(4) Flexibility of the operation, coal dust firing in this respect being almost equal to oil firing.

(5) Elimination of "banking" and easier disposal of ashes.

(6) Ease of control of furnace conditions in the case of metallurgical furnaces.

Of late years oil has been taking the place of coal in the generation of power in the movement of ships. Thus of the ships under construction in the year 1927 only about 31 per cent were those in which coal will be used, 69 per cent being driven by oil either to raise steam or used in internal combustion (Diesel) engines. The relative comparative efficiencies and costs of oil versus coal driven ships may be expressed as follows:—

The high efficiency of oil engines gives 1 S.H.P. for $\frac{4}{10}$ lb. of oil and 1 lb. of oil costs $\frac{4.3}{100}$ of a penny, so that 1 S.H.P. in a Diesel engine costs $\frac{1.7}{100}$ of a penny. In an ordinary marine steam engine and boiler, 1 S.H.P. requires 1·7 lb. of coal, which (with coal at 24/– per ton) costs $\frac{1.3}{100}$ of a penny, and one coal produced S.H.P. costs $\frac{2.2}{100}$ of a penny. In the particular case of "King George V.," built in 1926 and using high pressure steam, this has been reduced to $\frac{1.4}{100}$ of a penny, so that it has been demonstrated that coal is a cheaper fuel than oil for ship propulsion where high pressure steam is used, *i.e.*, 500 to 600 lb. per square inch. With pulverized fuel still further economies would be secured.

In America the development in the use of pulverized coal since 1920 has been exceptionally rapid and probably the world's consumption of pulverized fuel at the present time exceeds 150 million tons annually. In the United States of America the use of pulverized coal per annum has been estimated as follows:—

Cement kilns	50 million tons
Metallurgical furnaces	20 „ „
Steam boilers	30 „ „

On the Brazilian Central Railway some locomotives are being worked with pulverized coal derived from local deposits of inferior quality in place of using high-grade imported lump coal. In England also a system for locomotive use has been successfully developed.

PUMA, a name for one of the largest cats (*Felis concolor*) of the New World. It is called "couguar" by the French and "panther" by hunters of the United States (*see* CARNIVORA).

FROM MANN, WILD ANIMALS IN AND OUT OF THE ZOO (THE SMITHSONIAN SERIES)
THE PUMA OR MOUNTAIN LION. (FELIS CONCOLOR)

Though often spoken of as the mountain lion, on account of the tawny colour of its upper parts, it rather resembles the leopard of the Old World in size and habits: measuring from nose to root of tail about 40 in., the tail being rather more than half that length. The head is small and has no mane. The ears are large and rounded. The tail is cylindrical, with some bushy hairs near the end, but no distinct tuft. The lower parts, inner surface of the limbs, throat, chin, and upper lip are dirty white; the outside of the ears, and a patch on each side of the muzzle black; the end of the tail dusky. The young are born spotted a dusky brown and with the tail ringed.

The puma has a wide range, extending from Canada in the north to Patagonia in the south, and formerly was generally distributed in suitable localities from the Atlantic to the Pacific Ocean. In Central America it is still common in the dense forests which clothe the mountain ranges. Though an expert climber, it is by no means confined to wooded districts, being also found in scrub and reeds along the banks of rivers and in the open pampas and prairies. Its habits resemble those of the rest of the group to which it belongs. It rarely attacks man.

PUMICE, a very porous, froth-like, volcanic glass. It is an igneous rock which was almost completely liquid at the moment of effusion and was so rapidly cooled that there was no time for it to crystallize. When it solidified the vapours dissolved in it were suddenly released and the whole mass swelled up into a froth which immediately consolidated. Had it cooled under more pressure it would have formed a solid glass or obsidian (*q.v.*);

in fact if we take fragments of obsidian and heat them in a crucible till they fuse they will suddenly change to pumice when their dissolved gases are set free. Hence it can be understood that pumice is found only in recent volcanic countries. Any type of lava, if the conditions are favourable, may assume the pumiceous state; but basalts and andesites do not so often occur in this form as do trachytes and rhyolites. Pumices are most abundant and most typically developed from acid rocks; for which reason they usually accompany obsidians, in fact in Lipari and elsewhere the base of a lava flow may be black obsidian while the upper portion is a snow white pumice.

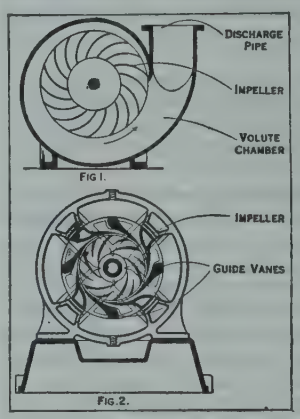
Small crystals of various minerals occur in many pumices; the most common are feldspar, augite, hornblende and zircon. If they are abundant they greatly diminish the economic value of the rock, as they are hard and wear down more slowly than the glassy material; consequently they produce scratches. The cavities of pumice are sometimes rounded, and may also be elongated or tubular owing to the flowing movement of the solidifying lava. The glass itself forms threads, fibres and thin partitions between the vesicles. Rhyolite and trachyte pumices are white, contain 60% to 75% of silica and the specific gravity of the glass is 2.3 to 2.4; andesite pumices are often yellow or brown; while pumiceous basalts, such as occur in the Sandwich Islands, are pitch black when perfectly fresh.

Good pumice is found in Iceland, Hungary, Nevada, Teneriffe, New Zealand, Pantelleria and the Lipari Islands. The last-named are the chief sources of pumice for the arts and manufactures. At Campo Bianco in Lipari there is an extinct volcanic cone with a breached crater from which a dark stream of obsidian has flowed. For industrial purposes the best varieties are obtained from Monte Pelato and Monte Chirica. The pumice is extracted by shafts and tunnels driven through the soft incoherent stone.

Among the older volcanic rocks pumice occurs, but usually has its cavities filled up by deposits of secondary minerals introduced by percolating water; hence it is of no value for industrial purposes. Pumice, in minute fragments, has been shown to have an exceedingly wide distribution over the earth's surface at the present day. It occurs in all the deposits which cover the floor of the deepest portion of the oceans, and is especially abundant in the abysmal red clay. In some measure this pumice has been derived from submarine volcanic eruptions, but its presence is also accounted for by the fact that pumice will float on water for months, and is thus distributed over the sea by winds and currents. After a long time it becomes waterlogged and sinks to the bottom, where it gradually disintegrates and is incorporated in the muds and oozes which are gathering there. After the great eruption of Krakatoa in 1883 banks of pumice covered the surface of the sea for many miles and rose in some cases for four or five feet above the water level. In addition much finely broken pumice was thrown into the air to a great height and was borne away by the winds, ultimately settling down in the most distant parts of the continents and oceans. Pumice stone has been satisfactorily used as a packing material for vinegar generators, its porous nature affording large oxidation surfaces, which are favourable to the development of dilute alcoholic liquids (washes) into vinegar. (J. S. F.)

PUMP, a machine to raise or move fluids. The method to be adopted in raising the elevation or the pressure of a fluid depends largely on the volume to be handled and the magnitude of the lift. For large volumes the centrifugal pump is almost universally used. In its modern forms this type is capable of pumping against any pressure up to about 1,500 lb. per sq.in. Where small volumes are to be handled, under high heads, the reciprocating pump is more suitable, while where corrosive liquids are to be pumped, other types of air-lift pumps often offer advantages. (*See* VACUUM.)

Centrifugal Pump.—In its simplest form the centrifugal pump consists of an impeller fitted with vanes and rotating in a closed casing. Water is supplied to the centre of the impeller. Due to its rotating in the impeller its pressure is increased by centrifugal force, and it is delivered at the periphery with an increased pressure and a high velocity. The kinetic energy involved in this exit velocity would be wasted if no means were available for converting it into pressure energy before leaving the pump, and various means are adopted for affecting this conversion. In the majority of pumps the impeller is surrounded by a spiral volute chamber (fig. 1) whose area gradually increases in the direction of flow, so that the velocity is gradually reduced before the water leaves the pump. Such a device is capable of converting at most about 40% of the kinetic energy into pressure energy. Where higher efficiencies are required a ring of guide vanes is used, surrounding the impeller (fig. 2). These vanes are so designed as to receive the water without shock on leaving the wheel and to direct it through passages having gradually diverging walls into the collecting volute from which it is fed to the discharge pipe. In these passages the pressure increases as the velocity is gradually reduced, and under favourable circumstances such an arrangement is capable of converting some 75% of the kinetic energy into pressure energy.



FROM BIGSON, "HYDRAULICS AND ITS APPLICATIONS" (CONSTABLE & CO.)

FIG. 1.—CENTRIFUGAL PUMP WITH VOLUTE CHAMBER

FIG. 2.—CENTRIFUGAL PUMP WITH GUIDE VANES SURROUNDING IMPELLER

The necessary peripheral speed of a centrifugal pump increases with the working head, and since fluid frictional losses increase rapidly with the speed, the efficiency begins to fall off appreciably if the working head per impeller is more than about 150 feet. Where very high heads have to be handled, multi-stage pumps are used in which the water passes through one impeller after another in series. Pumps of this type are extensively used for boiler feed work and for hydraulic power pumping stations.

The characteristics of a centrifugal pump depend essentially on the vane angles of its impeller, and under suitable conditions its overall efficiency may attain a value as high as 85%. At the inner periphery the vane angle β (fig. 3) should be such that the water enters the impeller without shock. This condition is satisfied if tan $\beta = f_2/u_2$ where f_2 is the radial component of the velocity of the water, and u_2 is the peripheral velocity of the impeller at this point. At the point of discharge the vanes may either be radial, or may be curved forwards, or backwards from the direction of rotation depending upon the duty for which the pump is designed. If γ be the vane angle at this point, and if u_3 be the peripheral velocity and f_3 the radial component of velocity of the water, the gain of pressure head in the impeller is, neglecting frictional losses, equal to

$$\frac{u_3^2 - f_3^2 \operatorname{cosec}^2 \gamma + f_2^2}{2g} \text{ feet}$$

while if K represents the proportion of the kinetic energy of discharge which is converted into pressure energy in the volute chamber or guide vanes, the total gain of pressure in the pump is given by

$$u_{32}(K+1) + f_3^2 \operatorname{cosec}^2 \gamma (K-1) - 2Ku_3 f_3 \cot \gamma \text{ feet.}$$

In the majority of pumps the angle γ is between 30° and 75°, the value increasing with the height of lift.

Reciprocating Pumps.—These may be either of the single acting or double acting type. In the former, water is drawn into the pump through a suction valve on one stroke, and is forced out through the delivery valve on the return stroke. By fitting suction and delivery valves on both sides of the plunger, the pump becomes double acting.

The acceleration and retardation of the plunger at the ends of the stroke causes corresponding retardations and accelerations in the supply and delivery columns, and if these are long considerable momentum effects may be experienced. If the speed is

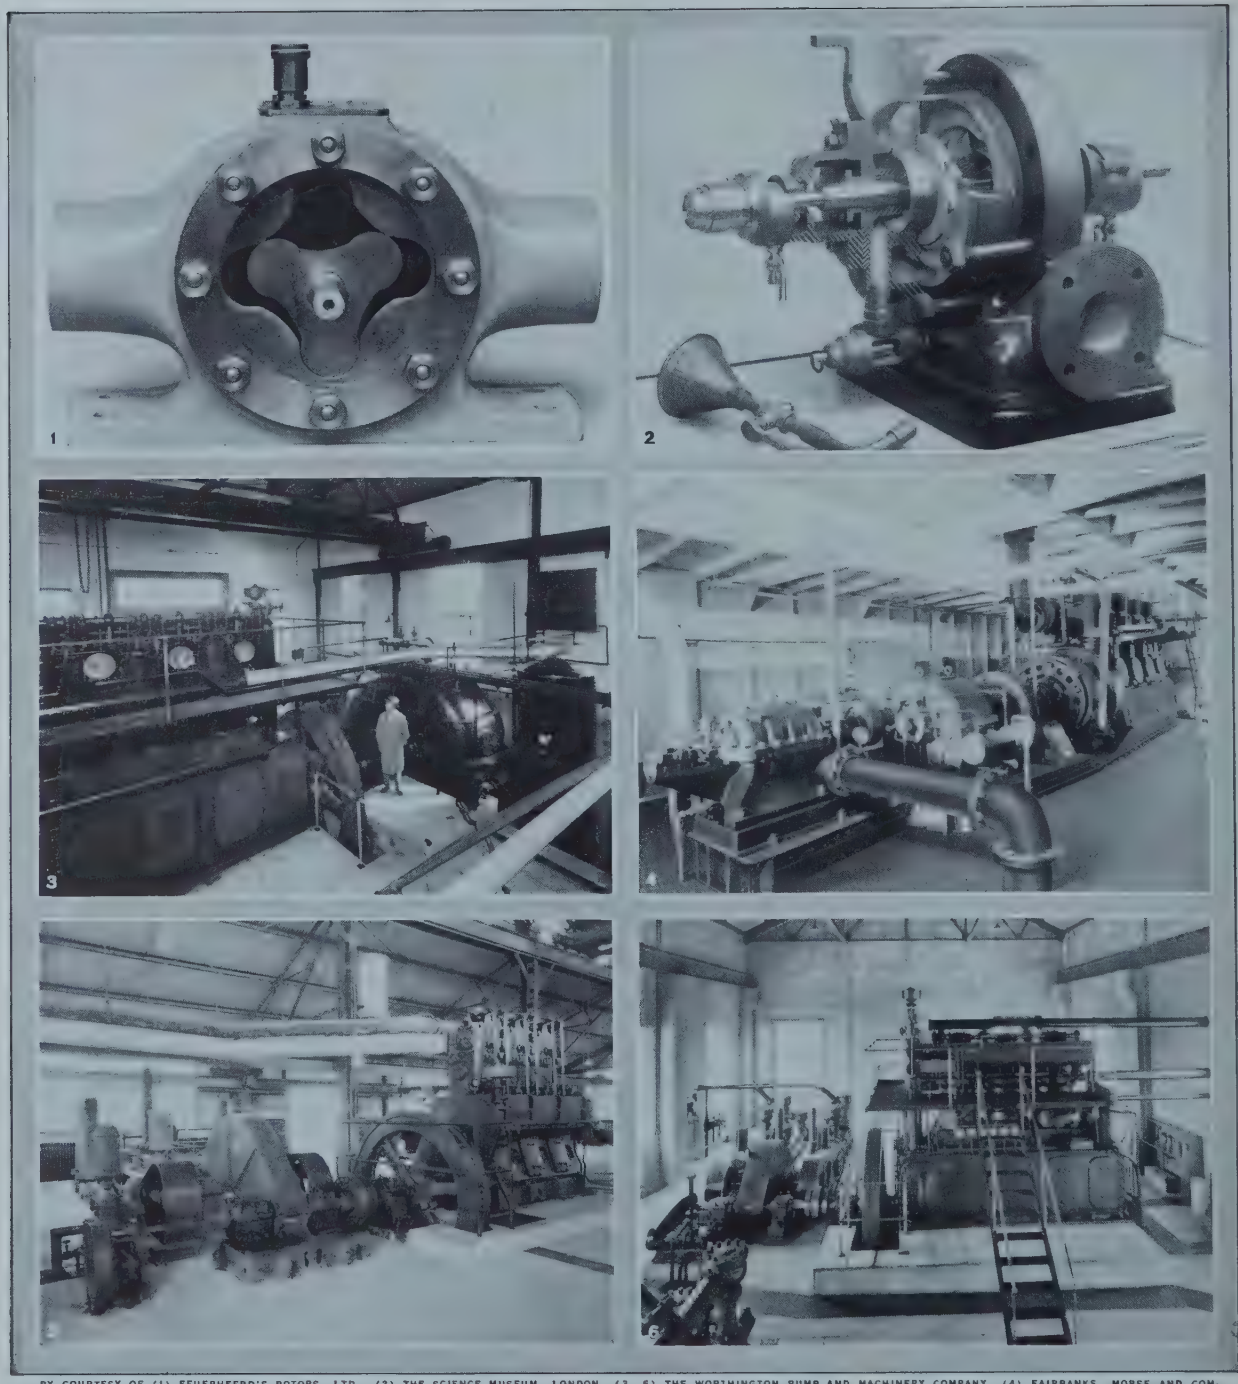
PUMP



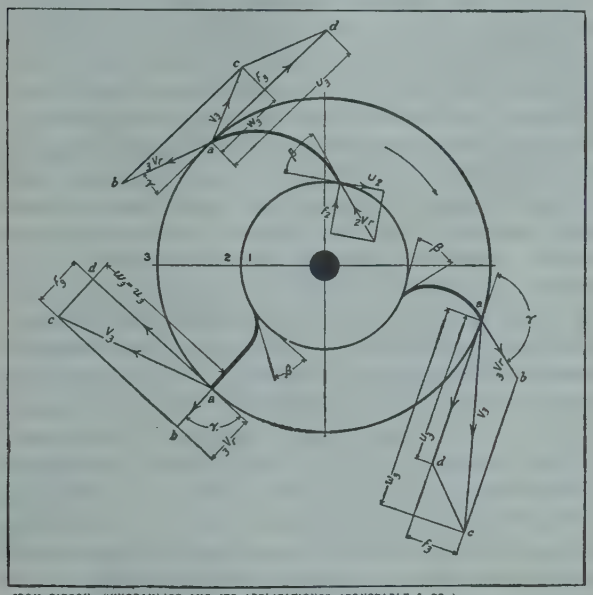
BY COURTESY OF (1) FEUERHEERD'S ROTORS, LTD., (2) THE SCIENCE MUSEUM, LONDON, (3. 6) THE WORTHINGTON PUMP AND MACHINERY COMPANY, (4) FAIRBANKS, MORSE AND COMPANY. (5) THE DE LA VERGNE MACHINE COMPANY

VARIOUS TYPES OF PUMPS

1. Rotary displacement pump
2. Section of a two-stage turbine pump
3. A 330 h.p. Diesel engine, connected to an 80-in. drainage pump, to the right
4. High pressure Diesel pump set, showing multi-stage pump to the left
5. A 200 h.p. Diesel engine, direct connected to a high-pressure plunger pump serving an oil pipe line
6. A 4-cycle air injection engine used in petroleum pipe line stations

sufficiently high the columns may be unable to maintain contact with the plunger and "cavitation" is set up, which gives rise to considerable shock in the pump. To avoid this an air vessel should always be fitted on the suction side of the pump, and often on the delivery side. This equalizes the flow along the pipe lines.

For low speed pumps, disc valves of rubber or metal, which are returned to their seat either by the action of a spring or by their own elasticity, are usually used. For high speed pumps mechanically operated valves are often used.

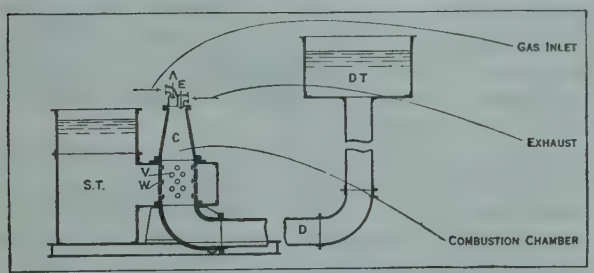


FROM GIBSON, "HYDRAULICS AND ITS APPLICATIONS" (CONSTABLE & CO.)

FIG. 3.—VELOCITY DIAGRAMS FOR VANES OF CENTRIFUGAL PUMP, HAVING DIFFERENT DEGREES OF BACKWARD CURVATURE

Rotary Pumps.—Pumps of the rotary type are well adapted for working over a wide range of speeds with comparatively low head and with widely varying discharges. They have the advantage over the reciprocating pump that the discharge is practically continuous, while the efficiency does not fall off nearly so quickly with discharge variations as the centrifugal pump.

There are two main types of rotary pump. In one a drum mounted eccentrically in its casing carries one or more sliding diaphragms which make contact with the interior of the casing. In the other type two rotating drums are used mounted on parallel axes and coupled together by two equal gear wheels mounted on the shafts outside the casing.



FROM GIBSON, "HYDRAULICS AND ITS APPLICATIONS" (CONSTABLE & CO.)

FIG. 4.—HUMPHREY GAS PUMP

Humphrey Gas Pump.—In the Humphrey Gas Pump water is raised by the direct action of the pressure accompanying the explosion and expansion of a gas-air mixture. At the beginning of the power stroke a compressed charge of air and gas in the combustion chamber C (fig. 4) is ignited by an electric spark and expands forcing the column of water D between the combustion chamber and the delivery tank DT towards the tank and discharging part of it in the process. Due to the momentum of this column, expansion continues until the pressure at the lower part of the water column falls to atmospheric, when the suction valves V, communicating with the suction tank ST, open and water is drawn through them into the pipe. At the same time the exhaust valve is opened. When the momentum of the water column is exhausted it oscillates back, driving the products of combustion out of the combustion chamber until it reaches the exhaust valve, which it closes by impact; on the next rebound of the water column the gas inlet valve opens and a fresh charge is drawn in; at the end of the outward oscillation the gas inlet valve is closed and the returning oscillation compresses the charge which is fired as the column comes to rest.

The Air Lift Pump.—This consists of an open ended vertical lift pipe, of which the lower end is submerged in the liquid to be raised, and the upper end delivers into a discharge tank at the height which is required. Air is supplied from an air compressor through an air pipe to the lower end of the lift pipe, and rising in the form of small bubbles through the liquid in this pipe forms a mixture having a specific gravity lower than that of the liquid itself. The pressure of the liquid surrounding the pipe then raises the lighter mixture above the supply level and out of the top of the lift pipe. The possible lift depends upon the amount of air supplied and upon the depth of submersion of the bottom of the lift pipe. For best results the depth of submersion should be approximately 1·5 times the height of the lift. For high efficiency the air should be supplied to the lift pipe through a foot-piece having a series of small openings so arranged as to distribute the air in a series of small bubbles through the liquid. If well designed such a pump is capable of converting some 60% of the energy in the compressed air at the foot-piece into useful work in lifting water. Air lift pumps have been constructed for lifting against heads of upwards of 400 ft., and with lift pipe diameters up to about 15 inches.

Jet Pump.—In the jet pump a high pressure water supply is conducted to a small nozzle, whence it issues into a suction chamber as a jet having a high velocity and a relatively low pressure. The suction chamber surrounding the jet is connected to the suction reservoir. If the pressure at the jet is sufficiently low, water is lifted into this chamber and is forced by the impact of the high velocity jet into a discharge pipe, whose suction gradually increases in the direction of flow. There the kinetic energy is partially converted into pressure energy, enabling the pump to discharge against a head considerably higher than that of the suction reservoir. Owing to the loss due to eddy formation accompanying the admixture of the high and low velocity water, the efficiency of such a pump is low and does not usually exceed about 20%. When the fluid used for the high pressure jet is steam, the pump becomes the boiler feed injector so largely used in locomotive work.

The Hydraulic Ram.—This is an apparatus devised to utilize the energy of a water supply at a low head, to pump up part of this water to a height greater than that of the supply head. It consists of an inclined supply pipe leading straight into a valve-box which is fitted with a waste valve opening inwards, and a delivery valve opening outwards. This valve discharges the water into an air vessel from which it is delivered in a steady stream to the discharge pipe.

The action of the ram is as follows: The waste valve being opened, water is free to escape, and flow is set up along the supply pipe. The velocity of flow increases under the influence of the supply head until the dynamic pressure on the under side of the valve becomes sufficiently great to overcome its weight. The valve now closes rapidly and the sudden check to the momentum of the supply column causes a rapid increase of pressure in the valve-box until this pressure becomes sufficiently great to open the delivery valve. Water then escapes through this valve into the air vessel, compresses the air, and flows away along the rising main. As soon as the momentum of the supply column is destroyed the delivery valve closes, the water below the valve partaking of the backward motion thus instituted. This motion, once set up, can only be checked by a reduction of pressure in

the valve-box below that corresponding to the statical head of the supply, and consequently the pressure in the valve-box is reduced rapidly until at some instant the waste valve reopens, and the whole cycle of operations is repeated. The efficiency of the hydraulic ram falls off as the ratio of the delivery head to the supply head is increased. When this ratio does not exceed about 4 : 1, the efficiency may be high as 75%. If the ratio is increased to 20 : 1 the efficiency does not exceed about 25%.

A pumping device known as the "Hydrotomat" has been recently introduced which also utilizes a large quantity of water under a low head to raise a portion of itself to some greater height. This works by alternately compressing and exhausting air in a series of containers.

PUMPKIN, the fruit of certain varieties of *Cucurbita pepo* or of *C. moschata,* members of the family Cucurbitaceae. The names pumpkin and squash, especially in America, are applied rather inconsistently to certain varieties of both these species. The quick-growing, small-fruited bush or nontrailing varieties of *C. pepo* (*see* SQUASH) are called squash in America, while the long-season, long-trailing, large-fruited varieties are called pumpkin. The fruits are large, generally 10–20 lb. or more, yellowish to orange in colour and vary from oblate through globular to oblong. The rind is smooth and usually lightly furrowed or ribbed; the fruit stem is hard and woody, ridged or angled, and in *C. pepo* not flared at its point of attachment to the fruit. The very largest varieties of "pumpkin" are more properly designated as winter squash, *C. maxima,* and may weigh 75 lb. or more. Varieties cross-pollinate very readily within each of the three species mentioned, but the species do not cross naturally. A few interspecific crosses have been recorded but the hybrids were highly self-sterile and set no fruit with their own pollen. Neither pumpkins nor squashes will cross with cucumbers or with melons.

Pumpkins are commonly grown in Great Britain, Europe and North America for human food and also for livestock feed. The varieties commonly called pumpkin produce very long vines and are usually planted in hills of 2–3 plants each, about 8 × 8 ft. apart. They are also planted at wide intervals in fields of corn. Pumpkins mature in early fall and can be stored a few months in a dry place well above freezing. They are prepared for food in a wide variety of ways. (V. R. B.)

PUNAN. The name applied to a number of peoples in Borneo, all of them, except the Punan Ba, forest nomads in the area of the headwaters of the major rivers. They live in isolated groups of 30 to 40, subsisting on the wild sago palm and game hunted with the blowpipe. Physically and culturally they are very similar to the other peoples of the island; none of them is Negrito or demonstrably aboriginal in Borneo. Some of the groups differ widely from each other and there is no indication why they should all be called Punan. As a result of this similarity of name European accounts of them are almost inextricably confused. Three "Punan" peoples, however, are certainly distinct: the settled Punan Ba of western Borneo; the Penan (wrongly named Punan) of the Baram and Balui; and the Punan Aput and Busang of the northern Apo Kayan. (R. NM.)

PUNCH, the abbreviated form of Punchinello (Ital. *Policinella, Pulcinella*), the most popular of the puppets or marionettes (*q.v.*), and the chief figure in the "Punch and Judy" show. It is of Italian origin, though its history is by no means free from obscurity. The earlier etymologists sought to trace the name to various mythical individuals, by whom, it was alleged, the type was first furnished. F. Galiani adopts the theory which derives it from the name of Puccio d'Aniello, a vintager of Acerra near Naples, who, having by his wit and grotesque appearance vanquished some strolling comedians in their own sphere, was induced to join the troop, and whose place, by reason of his popularity, was supplied after his death by a masked actor who imitated his dress and manner. The claims of other individuals—Paolo Cinella, Polliceno and Pulcinella, a Neapolitan dealer in fowls—have also found supporters, and the derivation of the name and character from some old mystery representing Pontius (O. Eng. *Pownce;* Fr. *Ponce*) Pilate and Judas, or the Jews, was formerly popular. It has even been suggested that the title is a modification of πολὺ κινέω (I move much) as expressive of the restlessness which is characteristic of the puppet; and the assumption that the character was invariably of diminutive size has given rise to its reference to the word *pollice,* the thumb (cf. *Däumling,* Tom Thumb). The most plausible theory, however, regards the name in its Italian form as a diminutive of *pulcino,* fem. *pulcina,* a chicken. It is sometimes stated that, in consequence of the habit of using the word "chicken" as a term of endearment, it came to mean "a little child," and hence "a puppet" (W. Skeat). The choice, however, seems to lie between the theory of Quadrio, that it was applied on account of the resemblance of the hooked nose to a beak, and that of J. Baretti, which ascribes its employment to the nasal squeak and timorous impotence of the original character. With respect to the development of the modern type, it has been assumed that the whole family of Italian *maschere* (Arlecchino, Brighella and the like) are modified survivals of the principal Oscan characters of the *Atellanae,* and that Punchinello is the representative of Maccus, the fool or clown. In proof of this it is urged that Acerra, the supposed residence of Puccio d'Aniello and the traditional source of the character, is in the neighbourhood of Aversa, the old Atella; and reference is also made to a bronze statue of Maccus, discovered at Rome in 1727, an engraving of which has been preserved in Ficoroni's *Le Maschere sceniche e le figure comiche d'antichi Romani.* But the resemblance of the statue to the puppet is scarcely a striking one, and the large nose and deformed figure are somewhat hazardous ground on which to base a theory.

Andrea Perrucci (1699) and Gimma assert with some show of authority that Silvio Fiorillo, a comedian named after his principal part, Captain Matamoros (the Italian *Miles Gloriosus*), invented the Neapolitan Pulcinella. It was afterwards improved by Andrea Calcese, surnamed Ciuccio, who died of the plague in 1656, and who, according to Gimma, imitated in the character the peasants of Acerra. This would place the origin of the Italian Pulcinella somewhere about the commencement of the 17th century, the original character appearing to have been that of a country clown, hook-nosed, shrill-voiced, cowardly, boastful and often stupid, yet given at times to knavish tricks and shrewd sayings. In thorough accordance with this date, we find that the earliest known appearance of Polichinelle in France is at the beginning of the reign of Louis XIV, in the show of the puppet-playing dentist Jean Brioché. The date of its introduction into England has been disputed, J. Payne Collier being of opinion that Punch and King William came together, a second theory suggesting an earlier origin with the Huguenot refugees.

It is more than probable that it crossed the channel in the wake of the Royalists. Apart from the general references by S. Pepys (1662) and by J. Evelyn (1667) to an Italian puppet show at Covent Garden, the former makes mention (1669) of some poor people who called their fat child Punch, "that word being become a word of common use for all that is thick and short." An allusion to "Punchinellos" is also to be found in Butler's satire on English imitation of the French, and Aubrey speaks of "a Punchinello holding a dial" as one of the ornaments of Sir Samuel Lely's house at Whitehall. But, though the puppet did not travel in the train of William of Orange, allusions to it became far more frequent after the Revolution of 1688, and the skill of the Dutch in their treatment of puppet mechanism may have enhanced its attractiveness. In 1703 it was introduced at Bartholomew Fair into a puppet play of the creation of the world; in 1709 (*Tatler,* No. 16) it was to be found in a representation of the Deluge, though in a different part from that of the Momus Polichinelle of Alexis Piron's *Arlequin-Deucalion* (1722); and in 1710 (*Spectator,* No. 14) it is mentioned as a leading figure in Powell's

puppet-show at Covent Garden. The alleged satire on Robert Walpole, entitled *A Second Tale of a Tub, or the History of Robert Powell, the Puppet-Showman* (1715), furnishes some details of Punch performances, and has an interesting frontispiece representing Powell with Punch and his wife. The Judy (or Joan, as she appears to have been sometimes called) is not of a specially grotesque order, but the Punch is easily recognizable in all but the features, which are of the normal puppet type.

The older Punchinello was far less restricted in his actions and circumstances than his modern successor. He fought with allegorical figures representing want and weariness as well as with his wife and with the police, was on intimate terms with the patriarchs and the seven champions of Christendom, sat on the lap of the queen of Sheba, had kings and dukes for his companions. Powell seems to have introduced a trained pig which danced a minuet with Punch, and the French (among whom Punch is now usually styled Guignol, originally a puppet hailing from Lyons) occasionally employed a cat in the place of the dog Toby, whose origin is somewhat uncertain. A typical version of the modern play, with illustrations, was published by Payne Collier and Cruikshank in 1828 (3rd ed., 1844).

PUNCHING AND SHEARING MACHINES. The quickest method of making holes in, or severing, materials is by punching or shearing, and there are few forms of manufacture that do not utilize machines for these operations. Paper, card, leather, cotton, cloth, slate, tin, brass, iron and steel all undergo such treatment. Circular and other shaped holes are made, pieces are punched out to give various outlines, and various shapes are sheared off. The most striking examples are in steel works, where blades of 12 feet in length will shear through 2 in. cold steel plate, or hot slabs 43 in. by 20 in. thick are cut through. Many industries are suited by hand-worked machines, others require belt, electric motor or steam-engine drive, while the largest punches and shears are worked hydraulically. Hand machines are employed by tinsmiths and other light metalworkers, also by boxmakers, and these machines rest on the bench. Larger punches or shears are actuated by treadle, the latter machines having blades up to about 4 feet in length. Some have blades formed to cut curves in tinplate or iron plate, instead of using a die to stamp the outlines, and corrugated blades are used for shearing corrugated iron. Blacksmiths and others make use of a combined type of machine, with a single lever moving the punch and the shear blade. This principle is also applied in many big machines of the engineering works, but using power drive.

Punching and shearing are alike in action which amounts to a rather violent separation of the fibres of the material. In soft substances there is little injury, because the cutting edges can be

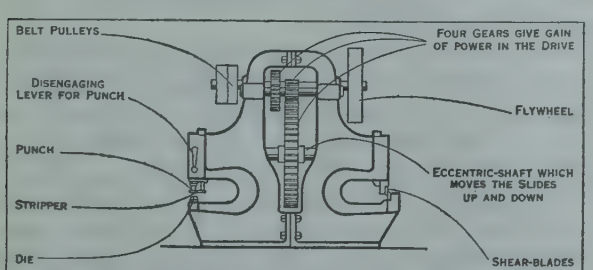

DIAGRAM OF A PUNCHING AND SHEARING MACHINE, WHICH PUNCHES AT ONE END AND SHEARS AT THE OTHER

made of a keen angle, but iron and steel become more or less torn unless very thin, and the edge reveals minute cracks. For certain purposes these would be undesirable, as tending to increase under stress; consequently plates and strips for steam-boilers are not punched, but drilled for reasons of safety. And where structures are subject to heavy loads of a fluctuating nature, the best plan is undoubtedly to ream punched holes, the reamer taking away the cracked and torn walls and leaving a smooth and whole surface. Shorn plates for boilers and certain other constructions are also machined on the edges, by turning, planing or milling, until a clean faultless metal is left. Obviously in order to ensure neat punching or shearing, as well as to minimize cracks and damaged edges, the tools should be kept ground up sharp, and set so that the material is well supported at the moment of impact. In a great many cases a slotted finger, termed a *stripper*, is fixed a fraction of an inch above the material, so that as the punch rises after the stroke the material cannot be pulled up with it, but is automatically stripped off. Some substances, especially when laid in piles for simultaneous treatment, must be clamped down firmly to prevent faulty results, while the thicker steel plates are held immovably by a mechanically-operated clamping device which comes into play just before the descent of the slide. Hydraulic vice rams perform this function in the large hydraulic shears of the steel-works. In rolling-mills, plates and slabs are transported under the shear on sets of power-driven rollers.

Types of Punching and Shearing Machines.—The power-driven punching machines vary in design according to whether the material is thin or thick. For the general run of tinware and similar thin stock the crank-driven power-presses are used, being of much the same or identical design as for other operations on sheetmetal parts. The machine frame must be stiff, and if necessary braced with tie-rods to prevent spring, otherwise the act of penetration will cause the punch and die to come out of alignment, and they will be injured, and poor work will result. The slide which moves the punch up and down must be well fitted, as any slackness will have a similar effect. The fit of the punch in the die, through which it pushes the punching, must be fairly close to ensure getting a sharp impression around the edges. The fit is closer in very thin metal than it need be in thick stuff. Many special mandrels or supports are attached to presses to carry the lower die when the object is of a difficult outline, such as a pipe.

For engineering manufactures, including all sorts of steel construction (boilers excepted), ships, agricultural machinery, tanks, cisterns, piping, fencing, railway carriage and wagon frames and so on, the punching machines are either single or multiple, or are combined in one frame with a shearing machine, so that one drive actuates each slide (see the sketch). The punch slide has a disengaging device, rendering the punch inoperative until the attendant has accurately located the plate beneath it, whereupon he pulls a little lever and the punch descends. The purpose of the flywheel is to give a reserve of energy to carry the punch or shear through the metal. The larger machines possess self-contained jib cranes, enabling heavy plates to be slung and moved along as necessary without keeping the shop crane engaged. Punching-machines only have an eccentric action to the slide (similar in principle to that of the diagram) and are often double-ended, using a differently sized punch in each slide. Instead of eccentric motion, powerful levers are often utilized in collaboration with a central eccentric which rocks them and so moves each slide. Sometimes a third slide is included in a double-ended punching and shearing machine to cut angle-iron, which requires a special shape of blade. Provision for shearing off angles, tees, channels, girders or H-irons is incorporated in some machines, there being apertures of corresponding section through which the shapes are pushed and sheared by a knife behind. The framings of such machines are frequently made in either cast-steel or steel plates riveted together, to afford extra strength without such weight as is necessary for cast-iron framings.

Multiple punching is greatly in favour because of the economy of production. The regular machines may have an attachment to take two or three punches, but otherwise a special machine has to be used, with a wider slide than usual. The punches are either adjustable as to distance apart, or fixed in this respect. Plates and bars for tanks, agricultural machines, carriages and wagons and various machinery may have any number up to 100 holes pierced at a stroke. If several rows must be put through a sheet (as for mine screens) the sheet can be handled rapidly on an automatic spacing table, which feeds it accurately to the successive positions past the punches. Alternatively the plate may remain stationary and the punching head travel intermittently to the successive positions.

The massive shears required in steel works and those making

big boilers are actuated by powerful gearing and eccentrics, or by hydraulic cylinders. The parts must be extremely strong in order to withstand the enormous force exerted at the moment of shearing and powerful spring buffers are often provided to take the shock as the blade goes through the plate. In these, as in most other shears, the blade is set at an angle so that it only shears progressively from one end to the other.

Hydraulic action furnishes a simpler mode of actuating a punch or shear slide than gearing in some of the shipyards, for punching big holes necessary in some of the plates. Portable machines for either punching or shearing are often used in the yards, being either carried about or transported on wheels. The working of a lever operates the pump and sends water to the actuating cylinder. Small machines are termed punching bears.

Rotary shears are so named because bevel-edged discs are used for the shearing. Some cut straight, others in circles, the plate being rotated on a central stud. Both circles and rings are sheared thus in large numbers for the tinware industry and other branches requiring these forms to build up shapes, or to stamp to further outline in dies. Some are built as *slitting shears*, that is suitably to make a long straight cut to divide a plate in two, or shear it up into strips, and there are also *scroll shears* which will cut intricate outlines between the discs, the attendant suitably manoeuvering the sheet as he feeds it along. (F. H.)

PUNCTUATION, the art of "pointing" a literary composition so as to divide it into sentences and portions of sentences, which the "points" mark at their close, thus indicating what would in speech be pauses or changes of expression (Lat. *punctum*, a point). The uses of the chief "points" are thus explained in the "Rules for Compositors" at the Oxford University Press, compiled by Mr. Horace Hart:—

The "full stop" or "period" (.) marks the end of a sentence. The "colon" (:) is at the transition point of the sentence. The "semicolon" (;) separates different statements. The "comma" (,) separates clauses, phrases and particles. (The terms "period," "colon," "comma," were borrowed from the Greek grammarians, who originally described either the whole sentence or a part of it in this way.) The "dash" (—) marks abruptness or irregularity. The "exclamation" (!) marks surprise. The "interrogation" or "query" (?) asks a question. The apostrophe (') marks elisions or the possessive case. "Quotes," quotation-marks or "inverted commas" (" ") define quoted words. Interpolations in a sentence are marked by various forms of bracket () or parenthesis. Usage and practice vary however. The subject may be studied in such works as H. Beadnell's *Spelling and Punctuation*, P. Allardyce's *Stops: or how to punctuate*, and T. L. de Vinne's *Correct Composition*. In the earlier forms of writing the letters ran on continuously in lines; only by degrees were words divided up by spacing within the line; later came the distribution into sentences by points, and the introduction by Aldus Manutius (16th century) of a regular system for these. The chief signs were derived from the dots of the Greek grammarians, but these have often changed meanings; thus the Greek interrogation mark (;) becomes the semicolon. (*See* PALAEOGRAPHY and TYPOGRAPHY.)

PUNIC WARS, a name specially appropriated to the wars between Rome and Carthage in the 3rd and 2nd centuries B.C. The origin of these conflicts is to be sought in the position which Rome acquired about 275 B.C. as suzerain and protector of all Italy. Her new obligation to safeguard the peninsula against foreign interference made it necessary that she should not allow the neighbouring island of Sicily to fall into the hands of a strong and expansive power. Carthage, on the other hand, had long been anxious to conquer Sicily and so to complete the chain of island posts by which she controlled the western Mediterranean.

First Punic War (264–241 B.C.[1]).—The proximate cause of the first outbreak was a crisis in the city of Messana, commanding the straits between Italy and Sicily. A band of Campanian mercenaries, which had forcibly established itself within the town and was being hard pressed in 264 by Hiero II. of Syracuse, applied for help both to Rome and Carthage and thus brought a force from either power upon the scene. The Carthaginians, arriving first, occupied Messana and effected a reconciliation with Hiero. The Roman commander nevertheless persisted in throwing troops into the city, and by seizing the person of the Carthaginian admiral during a parley induced him to withdraw. The Romans thus won an important strategic post, but their aggression met a declaration of war from Carthage and Syracuse.

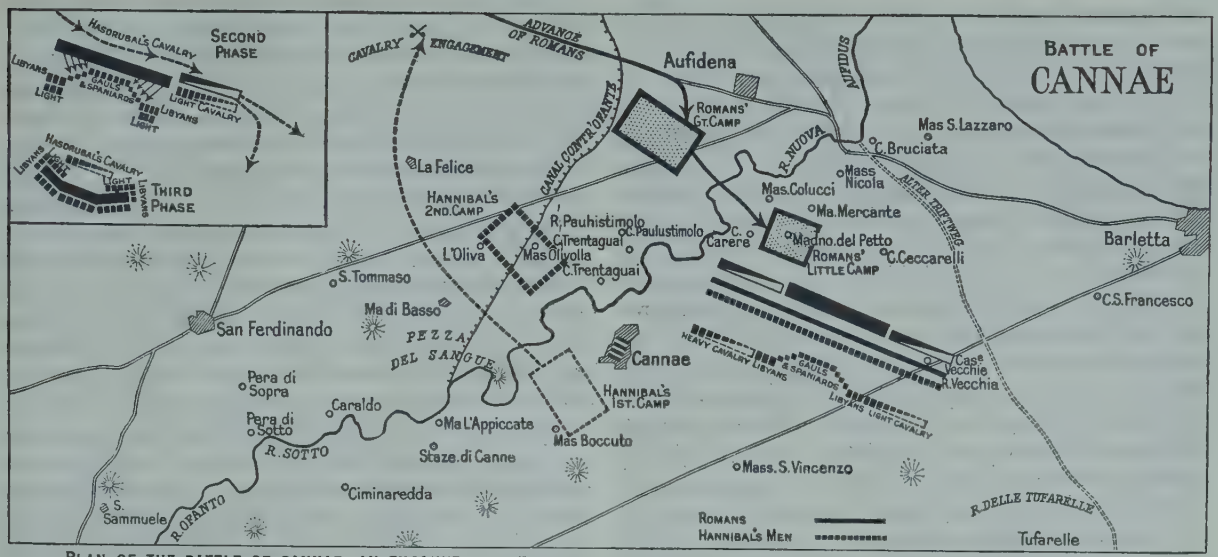
Operations began with a joint attack upon Messana, which the Romans easily repelled. In 263 they advanced with a considerable force into Hiero's territory and induced him to seek peace and alliance with them. Having thus secured their foothold on the island they set themselves to wrest it completely from Carthage. In 262 they besieged and captured the enemy's base at Agrigentum, and proved that Punic mercenary troops could not stand before the infantry of the legions. But they made little impression upon the Carthaginian fortresses in the west of the island and upon the towns of the interior which mostly sided against them. Thus in the following campaigns their army was practically brought to a standstill.

In 260 the war entered upon a new phase. Convinced that they could gain no serious advantage so long as the Carthaginians controlled the sea and communicated freely with their island possessions, the Romans built their first large fleet of standard battleships. At Mylae, off the north Sicilian coast, their admiral C. Duilius defeated a Carthaginian squadron of superior manoeuvring capacity by a novel application of grappling and boarding tactics. This victory left Rome free to land a force on Corsica and expel the Carthaginians (259), but did not suffice to loosen their grasp on Sicily.

After two more years of desultory warfare the Romans decided to carry the war into the enemy's home territory. A large armament sailed out in 256, repelled a vigorous attack by the entire Carthaginian fleet off Cape Ecnomus (near Agrigentum) and established a fortified camp on African soil at Clypea. The Carthaginians, whose citizen levy was utterly disorganized, could neither keep the field against the invaders nor prevent their subjects from revolting. A single campaign compelled them to sue for peace, but the terms which the Roman commander Atilius Regulus offered were intolerably harsh. Accordingly they equipped a new army in which, by the advice of a Greek captain of mercenaries named Xanthippus, cavalry and elephants formed the strongest arm. In 255, under Xanthippus's command, they offered battle to Regulus, who had taken up position with an inadequate force near Tunis, outmanoeuvred him and destroyed the bulk of his army. A second Roman armament, which subsequently reached Africa after defeating the full Carthaginian fleet off Cape Hermaeum, did not venture to reopen the campaign, but withdrew all the remaining troops.

The Romans now directed their efforts once more against Sicily. In 254 they carried the important fortress of Panormus (Palermo) by an attack from the sea; but when Carthage threw reinforcements into the island the war again came to a standstill. In 251 at last the Roman general L. Metellus brought about a pitched battle near Panormus in which the enemy's force was effectively crippled. This victory was followed by an investment of the chief Punic base at Lilybaeum by land and sea. The besiegers met with a gallant resistance, and in 249 were compelled to withdraw by the loss of their fleet in a surprise attack upon the neighbouring harbour of Drepanum (Trapani), in which the admiral Claudius Pulcher was repulsed with a loss of 93 ships. Meanwhile other losses in storms on the high seas so reduced the Roman fleet that the attack upon Sicily had to be suspended. At the same time the Carthaginians, who felt no less severely the financial strain of the prolonged struggle and had a war in Africa on their hands, reduced their armaments and made no attempt to deliver a counter-attack. The only noteworthy feature of the ensuing campaigns is the skilful guerrilla war waged by a new Carthaginian commander, Hamilcar Barca, from his strong positions on Mt. Ercte (247–244) and Mt. Eryx (244–242) in western Sicily, by which he effectually screened Lilybaeum from the Roman land army.

[1]The chronology here given is the traditional one, but recent researches tend to show that many events have been antedated by one year



PLAN OF THE BATTLE OF CANNAE, AN ENCOUNTER OF THE SECOND PUNIC WAR, WHERE THE ROMANS WERE PRACTICALLY ANNIHILATED BY HANNIBAL IN 216 B.C.

In 242 Rome resumed operations on sea. By a magnificent effort on the part of private citizens a fleet of 200 warships was equipped and sent out to renew the blockade of Lilybaeum. The Carthaginians hastily collected a relief force, but in a battle fought off the Aegates or Aegusae islands (west of Drepana) their fleet was caught at a disadvantage and mostly sunk or captured (March 10, 241). This victory, by giving the Romans undisputed command of the sea, rendered certain the ultimate fall of the Punic strongholds in Sicily. The Carthaginians accordingly opened negotiations and consented to a peace by which they ceded Sicily and the Lipari islands to Rome and paid an indemnity of 3,200 talents (about £800,000).

The Interval Between the First and Second Wars (241–218 B.C.).—The loss of naval supremacy not only deprived Carthage of her predominance in the western Mediterranean, but exposed her oversea empire to disintegration under renewed attacks by Rome. The temper of the Roman people was soon made manifest during a conflict which broke out between the Carthaginians and their discontented mercenaries. Italian traders were allowed to traffic in munitions of war with the mutineers, and a gross breach of the treaty was perpetrated when a Roman force was sent to occupy Sardinia, whose insurgent garrison had offered to surrender the island (239). To the remonstrances of Carthage the Romans replied with a direct declaration of war, and only withheld their attack upon the formal cession of Sardinia and Corsica and the payment of a further indemnity.

From this episode it became clear that Rome intended to use her victory to the utmost. To avoid complete humiliation Carthage had no resource but to humiliate her adversary. The recent complications of foreign and internal strife had indeed so weakened the Punic power that the prospect of renewing the war under favourable circumstances seemed remote enough. But the scheme of preparing for a fresh conflict found a worthy champion in Hamilcar Barca, who sought to compensate for the loss of Sicily by acquiring a dominion in Spain where Carthage might gain new wealth and form a fresh base of operations against Rome. Invested with an unrestricted foreign command, he spent the rest of his life in founding a Spanish empire (236–228). His work was continued by his son-in-law Hasdrubal and his son Hannibal, who was placed at the head of the army in 220. These conquests aroused the suspicions of Rome, which in a treaty with Hasdrubal confined the Carthaginians to the south of the Ebro, and also guaranteed the independence of Saguntum, a town on the east coast which pretended to a Greek origin. In 219 Hannibal laid siege to Saguntum and carried the town in spite of a stubborn defence. It has always been a debatable point whether his attack contravened the new treaty. The Romans certainly took this view and sent to Carthage to demand Hannibal's surrender. But his defiant policy was too popular to be disavowed; the Carthaginian council upheld Hannibal's action, and drew upon itself a declaration of war.

Second Punic War (218–201 B.C.).—It seemed as though the superiority of the Romans at sea must enable them to choose the field of battle. They decided to embark one army for Spain and another for Sicily and Africa. But before their preparations were complete Hannibal began that series of operations by which he dictated the course of the war for the greater part of its duration. Realizing that so long as Rome commanded the resources of an undivided Italian confederacy no foreign attack could beat her down beyond recovery, he conceived the plan of cutting off her supply of strength at the source by carrying the war into Italy and causing a disruption of the League. His chances of ever reaching Italy seemed small, for the sea was guarded by the Roman fleets and the land route was long and arduous. But the very boldness of his enterprise contributed to its success; after a six months' march through Spain and Gaul and over the Alps, which the Romans were nowhere in time to oppose, Hannibal arrived in the plain of the Po with 20,000 foot and 6,000 horse, the pick of his African and Spanish levies (autumn 218: for details *see* HANNIBAL).

His further advance was here disputed by some Roman troops which had been recalled from the Spanish expedition. But the superiority of the Carthaginian cavalry and the spread of insurrection among the Gaulish inhabitants forced the defenders to fall back upon the Apennines. At the end of the year the Roman army was reinforced by the division from Sicily and led out to battle on the banks of the Trebia (*q.v.*). Hannibal, by superior tactics, repelled the assailants with heavy loss, and thus made his position in north Italy secure.

In 217 the campaign opened in Etruria, into which the invading army, largely reinforced by Gauls, penetrated by an unguarded pass. A rash pursuit by the Roman field force led to its being entrapped on the shore of Lake Trasimene (*q.v.*) and destroyed with a loss of 40,000 men. This catastrophe left Rome completely uncovered; but Hannibal, having resolved not to attack the capital before he could collect a more overwhelming force, directed his march towards the south of Italy, where he hoped to stir up the peoples who had formerly been Rome's most stubborn enemies. The natives, however, were everywhere slow to join the Carthaginians, and a new Roman army under the dictator Q. Fabius Maximus ("Cunctator"), which, without ever daring to close with Hannibal, dogged his steps on his forays through Apulia and Campania, prevented his acquiring a permanent base of operations

The eventful campaign of 216 was begun by a new aggressive move on the part of Rome. An exceptionally strong field army, estimated at 85,000 men, was sent forth in order to crush the Carthaginians in open battle. On a level plain near Cannae (*q.v.*) in Apulia, which Hannibal had chosen for his battle-ground, the Roman legions delivered their attack. Hannibal deliberately allowed his centre to be driven in by their superior numbers, while Hasdrubal's cavalry wheeled round so as to take the enemy in flank and rear. The Romans, surrounded on all sides and so cramped that their superior numbers aggravated their plight, were practically annihilated, and the loss of citizens was perhaps greater than in any other defeat that befell the Republic. The moral effect of the battle was no less momentous. The south Italian nations at last found courage to secede from Rome, the leaders of the movement being the people of Capua, the second greatest town of Italy. Reinforcements were sent from Carthage, and several neutral powers prepared to throw their weight into the scale on Hannibal's behalf. At first sight it seems strange that the battle of Cannae did not decide the war. But the resources of Rome, though terribly reduced in respect both of men and of money, were not yet exhausted. In north and central Italy the insurrection spread but little, and could be sufficiently guarded against with small detachments. In the south the Greek towns of the coast remained loyal, and the numerous Latin colonies continued to render important service by interrupting free communication between the rebels and detaining part of their forces. In Rome itself the quarrels between the nobles and commons, which had previously unsettled her policy, gave way to a unanimity unparalleled in the annals of the Republic. The guidance of operations was henceforth left to the senate, which by maintaining a persistent policy until the conflict was brought to a successful end earned its greatest title to fame.

The subsequent campaigns of the Italian War assume a new character. Though the Romans contrived at times to raise 200,000 men, they could only spare a moderate force for field operations. Their generals, among whom the veterans Fabius and M. Claudius Marcellus frequently held the most important commands, rarely ventured to engage Hannibal in the open, and contented themselves with observing him or skirmishing against his detachments. Hannibal, whose recent accessions of strength were largely discounted by the necessity of assigning troops to protect his new allies or secure their wavering loyalty, was still too weak to undertake a vigorous offensive. In the ensuing years the war resolved itself into a multiplicity of minor engagements which need not be followed out in detail. In 216 and 215 the chief seat of war was Campania, where Hannibal vainly attempted to establish himself on the coast but experienced a severe repulse at Nola. In 214 the main Carthaginian force was transferred to Apulia in hopes of capturing Tarentum. Though Croton and Locri on the Calabrian coast had fallen into his hands, Hannibal still lacked a suitable harbour by which he might have secured his oversea communications. For two years he watched in vain for an opportunity of surprising the town, while the Romans narrowed down the sphere of revolt in Campania and defeated other Carthaginian commanders. In 212 the greater part of Tarentum and other cities of the southern seaboard at last came into Hannibal's power. But in the same year the Romans found themselves strong enough to place Capua under blockade. They severely defeated a Carthaginian relief force, and could not be permanently dislodged even by Hannibal himself. In 211 Hannibal made a last effort to relieve his allies by a feint upon Rome itself, but the besiegers refused to be drawn away from their entrenchments, and eventually Capua was starved into surrender. Its fall was a sign that no power could in the long run uphold a rival Italian coalition against Rome. After a year of desultory fighting the Romans in 209 gained a further important success by recovering Tarentum. Though Hannibal still won isolated engagements, he was being slowly driven back into the extreme south of the peninsula.

In 207 the arrival of a fresh invading force produced a new crisis. Hasdrubal, who in 209–208 had marched overland from Spain, appeared in north Italy with a force scarcely inferior to the army which his brother had brought in 218. After levying contingents of Gauls and Ligurians he marched down the east coast with the object of joining hands with his brother in central Italy for a direct attack upon Rome. By this time the drain of men and money was telling so severely upon her confederacy that some of her most loyal allies protested their inability to render further help. Yet by a supreme effort the Romans raised their war establishment to the highest total yet attained and sent a strong field army against either Carthaginian leader. The danger to Rome was chiefly averted by the prompt insight and enterprise of the consul C. Nero, who commanded the main army in the south. Having discovered that Hannibal would not advance beyond Apulia until his brother had established communications with him, Nero slipped away with part of his troops and arrived in time to reinforce his colleague Livius, whose force had recently got into touch with Hasdrubal near Sena Gallica (Sinigaglia). The combined Roman army frustrated an attempt of Hasdrubal to elude it and forced him to fight on the banks of the Metaurus (*q.v.*). The battle was evenly contested until Nero by a dexterous flanking movement cut the enemy's retreat. Hasdrubal himself fell and the bulk of his army was destroyed.

The campaign of 207 decided the war in Italy. Though Hannibal still maintained himself for some years in Calabria, this was chiefly due to the exhaustion of Rome after the prodigious strain of past years and the consequent reduction of her armaments. In 203 Italy was finally cleared of Carthaginian troops. Hannibal, in accordance with orders from home, sailed back to Africa, and another expedition under his brother Mago, which had sailed to Liguria in 205 and endeavoured to rouse the slumbering discontent in Cisalpine Gaul and Etruria, was driven back on the coast and withdrawn about the same time.

Campaigns in Sicily and Spain.—Concurrently with the great struggle in Italy the Second Punic War was fought out on several other fields. It will suffice merely to allude to the First Macedonian War (214–205) which King Philip V. commenced when the Roman power seemed to be breaking up after Cannae. The diversions which Roman diplomacy provided for Philip in Greece and the maintenance of a patrol squadron in the Adriatic prevented any effective co-operation on his part with Hannibal.

In view of the complete stagnation of agriculture in Italy the Romans had to look to Sardinia and Sicily for their food supply. Sardinia was attacked by a Carthaginian armament in 215, but a small Roman force sufficed to repel the invasion. In Sicily a more serious conflict broke out. Some isolated attacks by Punic squadrons were easily frustrated by the strong Roman fleet. But in 215 internal complications arose. The death of Hiero II., Rome's steadfast friend, left the kingdom of Syracuse to his inexperienced grandson Hieronymus. Flattered by the promises of Carthaginian emissaries the young prince abruptly broke with the Romans, but before hostilities commenced he was assassinated. The Syracusan people now repudiated the monarchy and resumed their republican constitution, but they were misled by false threats of terrible punishment at the hands of Rome to play into the hands of the Carthaginians. The attacks of a Roman army and fleet under Marcellus which speedily appeared before the town were completely baffled by the mechanical contrivances of the Syracusan mathematician Archimedes (213). Meantime the revolt against Rome spread in the interior, and a Carthaginian fleet established itself in the towns of the south coast. In 212 Marcellus at last broke through the defence of Syracuse and in spite of the arrival of a Carthaginian relief force mastered the town by slow degrees. A guerilla warfare succeeded in which the Carthaginians maintained the upper hand until in 210 they lost their base at Agrigentum. They were dislodged from their remaining positions, and by the end of the year Sicily was wholly under the power of Rome.

The conflict in Spain was second in importance to the Italian war alone. From this country the Carthaginians drew large supplies of troops and money which might serve to reinforce Hannibal; hence it was in the interest of the Romans to challenge their enemy within his Spanish domain. Though the force which Rome at first spared for this war was small in numbers and rested entirely upon its own resources, the generals Publius and Gnaeus Scipio by skilful strategy and diplomacy not only won over the peoples north of the Ebro and defeated the Carthaginian leader Hasdrubal

Barca in his attempts to restore communication with Italy, but carried their arms along the east coast into the heart of the enemy's domain. But eventually their successes were nullified by a rash advance. Deserted by their native contingents and cut off by Carthaginian cavalry, among which the Numidian prince Massinissa rendered conspicuous service, the Roman generals were slain and their troops were destroyed in detail (212 or 211).

Disturbances in Africa prevented the Punic commanders from reaping the full fruit of their success. Before long the fall of Capua enabled Rome to transfer troops from Italy to Spain, and in 209 the best Roman general of the day, the young son and namesake of the recently slain P. Scipio, was placed in command. The new leader signalized his arrival by a bold and successful *coup-de-main* upon the great arsenal of Carthago Nova (*see* CARTAGENA). Though he was unable to prevent Hasdrubal Barca from marching away to Italy, Scipio profited by his departure to push back the remaining hostile forces the more rapidly. A last effort by the Carthaginians to retrieve their losses with a fresh army was frustrated by a great victory at Ilipa (*q.v.*), near Corduba, and by the end of 206 they were driven out of Spain.

The War in Africa.—In 205 Scipio, who had returned to Rome to hold the consulship, proposed to follow up his victories by an attack upon the home territory of Carthage. Though the presence of Hannibal in Italy at first deterred the senate from sanctioning this policy, the general popularity of the scheme overbore all resistance. Scipio was granted a force which he organized and supplemented in Sicily, and in 204 sailed across to Africa. He was there met by a combined levy of Carthage and King Syphax of Numidia, and for a time penned to the shore near Utica. But in the winter he extricated himself by a surprise attack upon the enemy's camp, which resulted in the total loss of the allied force by sword or flame. In the campaign of 203 a new Carthaginian force was destroyed by Scipio on the Great Plains not far from Utica, their ally Syphax was captured, and the renegade Massinissa (*q.v.*) reinstated in the kingdom from which Syphax had recently expelled him. These disasters induced the Carthaginians to sue for peace, but before the very moderate terms which Scipio offered could be definitely accepted a sudden reversal of opinion caused them to recall Hannibal's army for a final trial of war, and to break off negotiations. In 202 Hannibal assumed command of a composite force of citizen and mercenary levies stiffened with a corps of his veteran Italian troops. After an abortive conference with Scipio he prepared for a decisive battle at Zama (*q.v.*), an inland site not yet identified with certainty. Scipio's force was smaller in numbers, but well trained throughout and greatly superior in cavalry. His infantry, after evading an attack by the Carthaginian elephants, cut through the first two lines of the enemy, but was unable to break the reserve corps of veterans. The battle was ultimately decided by the cavalry of the Romans and their new ally Massinissa, which by a manoeuvre recalling the tactics of Cannae took Hannibal's line in the rear and completely destroyed it. The Carthaginians having thus lost their last army again applied for peace and accepted the terms which Scipio offered. They were compelled to cede Spain and the Mediterranean islands still in their hands, to surrender their warships, to pay an indemnity of 10,000 talents (about £2,400,000) within 50 years and to forfeit their independence in affairs of war and foreign policy.

The Second Punic War, by far the greatest struggle in which either power engaged, had thus ended in the complete triumph of Rome. This triumph is not to be explained in the main by any faultiness in the Carthaginians' method of attack. The history of the First Punic War, and that of the second outside of Italy, prove that the Romans were irresistible on neutral or Carthaginian ground. Carthage could only hope to win by invading Italy and using the enemy's home resources against him. The failure of Hannibal's brilliant endeavour to realize these conditions was not due to any strategical mistakes on his part. It was caused by the indomitable strength of will of the Romans, whose character during this period appears at its best, and to the compactness of their Italian confederacy, which no shock of defeat or strain of war could entirely disintegrate. It is this spectacle of individual genius overborne by corporate and persevering effort which lends to the Second Punic War its peculiar interest.

The Third Punic War (149–146 B.C.).—The political power of Carthage henceforth remained quite insignificant, but its commerce and material resources revived in the 2nd century with such rapidity as to excite the jealousy of the growing mercantile population of Rome and the alarm of its more timid statesmen. Under the influence of these feelings the conviction—sedulously fostered by Cato the Elder, the Censor—that "Carthage must be destroyed" overbore the scruples of more clear-sighted statesmen. A *casus belli* was readily found in a formal breach of the treaty, committed by the Carthaginians in 154, when they resisted Massinissa's aggressions by force of arms. A Roman army was despatched to Africa, and although the Carthaginians consented to make reparation by giving hostages and surrendering their arms, they were goaded into revolt by the further stipulation that they must emigrate to some inland site where they would be debarred from commerce. By a desperate effort they created a new war equipment and prepared their city for a siege (149). The Roman attack for two years completely miscarried, until in 147 the command was given to a young officer who had distinguished himself in the early operations of the war—Scipio Aemilianus, the adopted grandson of the former conqueror of Carthage. Scipio made the blockade stringent by walling off the isthmus on which the town lay and by cutting off its sources of supplies from oversea. His main attack was delivered on the harbour side, where he effected an entrance in the face of a determined and ingenious resistance. The struggle did not cease until he had captured house by house the streets that led up to the citadel. Of a population probably exceeding half a million only 50,000 remained at the final surrender. The survivors were sold into slavery; the city was razed to the ground and its site condemned by solemn imprecations to lie desolate for ever. The territory of Carthage, which had recently been much narrowed by Massinissa's encroachments, was converted into a Roman province under the name of "Africa."

BIBLIOGRAPHY.—1. *Ancient Authorities.* For the First Punic War Polybius, bk. 1, provides a trustworthy and impartial account, but owing to his conciseness leaves many problems of chronology and strategy unexplained. For the Second War bk. 2 and 3 of Polybius present a complete and detailed record down to Cannae; bk. 7–15 contain fragmentary notices of which the most continuous deal with the campaigns of Scipio. Livy (bk. 23–30) gives a continuous and detailed narrative, partly based upon Polybius and other good authorities, partly upon untrustworthy Roman annalists. The Third War is described in Appian's *Res Libycae,* ch. 67 *sqq.,* and the fragments of Polybius, bk. 36–39.

The subsidiary authorities are: Diodorus, bk. 20–27, 32; Appian, *Res libycae, hispanicae, hannibalicae;* Zonaras' epitome of Dio Cassius, fr. 43, 54, 57; Plutarch's *Lives of Fabius and Marcellus;* Cornelius Nepos's *Lives of Hamilcar and Hannibal,* and short references in Justin, Eutropius, Aurelius Victor and Orosius. The sources and methods of composition of these authors have been discussed in numerous articles and dissertations, mostly German, of which the most important are mentioned in Niese's work (quoted below). These essays have brought out few certain results, but they trend to show that the narratives, so far as they are not based on Polybius or earlier authorities, are of little value.

PUNISHMENT, the infliction of some kind of pain or loss upon a person for a misdeed, *i.e.,* the transgression of a law or command. *See* CRIMINAL LAW; CRIMINOLOGY; CAPITAL PUNISHMENT; PRISON, etc.

PUNJAB, *i.e.,* land of the "five rivers" (viz., the Jhelum, Chenab, Ravi, Beas and Sutlej, all tributaries of the Indus), is the name given primarily to the triangle of country, in the Indian subcontinent, of which the Indus and the Sutlej to their confluence form the two sides, the base being the lower Himalaya hills between those two rivers. From 1848 to Aug. 1947, when British responsibilities were transferred to the dominions of India and Pakistan, the Punjab formed a British province, from which a separate North-West Frontier province was created in 1901 and from which certain territory in the east, including Delhi, was taken to form the Delhi enclave in 1912.

The geographical area of the Punjab, in addition to the British province, comprised about 35 states under the personal government of rulers who had treaty relations with the British crown. The largest of these states was Bahawalpur (17,494 sq.mi.; population 1,340,000 in 1951), on the left bank of the Sutlej and Indus. Except for Bahawalpur, all the other states lay in that portion of the Punjab which, after partition, was assigned to India. These were then formed into two groups: the Patiala and East Punjab States Union (10,099 sq.mi.; population 3,320,000), a "B" state under the constitution of the Republic of India; and the Himachal Pradesh (10,600 sq.mi.; population 1,100,000), a part "C" state under that constitution, administered by a chief commissioner of the government of India. The area of the West Punjab, assigned by partition to Pakistan, is 62,015 sq.mi., its population 20,634,000; that of the East Punjab, assigned to India, is 37,428 sq.mi., its population 12,638,611.

Partition set the boundary in the Punjab between India and Pakistan roughly along the line of the Sutlej up to beyond Ferozepur and then due north between Lahore and Amritsar to the boundary of Kashmir along the line of the Ravi. Under British rule, the Punjab was divided into five divisions: Umballa (Ambala), Jullundur, Lahore, Rawalpindi and Multan. Partition gave the Umballa and Jullundur divisions to India (East Punjab) and the Rawalpindi and Multan divisions to Pakistan (West Punjab). The Lahore division was divided so that the East Punjab took the Amritsar district and part of the Lahore district except the Chunian and Lahore tahsils (including, of course, the city of Lahore). The West Punjab took from the Lahore division, in addition to the Chunian and Lahore tahsils, the districts of Sialkot, Gujranwala and Sheikhupura, with certain portions of the Gurdaspur district.

The immediate result of partition in the Punjab was an outbreak of violence involving much loss of life and a mass movement of population from one part of the area to the other; so that the figures of population returned by the census of 1951 must be regarded as approximate only.

The total population of the Punjab (including states) according to the census of 1951 was 39,000,000. The Jats, who number about 6,000,000, form the backbone of the cultivating community. Large numbers of them became Sikhs or Mohammedans in the tracts where those religions predominate. The Rajputs, with a total of about 3,000,000, comprise tribes of different religions, races and social systems. By religion they are mostly Mohammedan, only about 40% being Hindus and 20% Sikhs. The Gujars are an important agricultural and pastoral tribe. Baluchis and Pathans are strongly represented in the southwest and west. Soldiers of the Punjab distinguished themselves in the Indian army's exploits in World Wars I and II.

Of the 28,490,857 people in the Punjab in 1931 about 21,893,342 spoke the provincial language, Punjabi, which varies in character in different parts of the province. About 3,988,000 spoke Hindustani (*see* HINDOSTANI LANGUAGE), this number including those whose ordinary vernacular was Hindi. These two languages were the most generally used throughout the province. The other languages in use were more or less local. The hill dialects, known as Pahari, are akin to the language spoken in Rajputana.

Physical Features.—The mountain regions of the Punjab fall under four separate groups. To the northeast of the country lies the Himalayan system, with the fringing range of the Siwaliks at its foot. In the southeastern corner the Aravalli system sends out insignificant outliers, which run across Gurgaon and Delhi districts and strike the Jumna at Delhi. The lower portion of the western frontier is constituted by the great Suliman chain; while the northwestern districts of the province are traversed by the hill system known as the Salt range.

The "five rivers" of the Punjab are each of large volume; but the great width of sandy channel in their passage through the plains, their changing courses and their shifting shoals make them worthless for steam navigation, though they all support a considerable boat traffic. They have been utilized for purposes of irrigation and have turned the sandy desert of the Punjab into a great wheat-growing area.

South of the Himalayas stretch the great alluvial plains from the Jumna on the east to the Sulimans in the west, one vast level, unbroken save by the wide eroded channels within which the great rivers ever shift their beds, by the insignificant spurs of the Aravalli range in the southeastern corner and by the low hills of Chiniot and Kirana in Jhang.

Geology.—By far the greater part of the Punjab is covered by alluvial and wind-blown deposits of the plain of the Indus. The Salt range hills form a plateau with a steeply scarped face to the south, along which there is an axis of abrupt folding, accompanied by faulting. The rocks found in the Salt range belong to the Cambrian, Carboniferous, Permian, Triassic and Jurassic systems, while Tertiary beds cover the plateau behind. The extensive and valuable deposits of salt, from which the range takes its name, occur near the base of the Cambrian beds. Gypsum, kieserite and other salts are found. Between the Cambrian and the Carboniferous beds there is an unconformity, which, however, is not very strongly marked, in spite of the lapse of time which it indicates. At the bottom of the Carboniferous series there is usually a boulder bed, the boulders having been brought from a distance and scratched and striated as if by ice. It is generally admitted that this deposit indicates a southern glacial period in late Carboniferous times. Above the sandstone series at the base of which the boulder bed lies come the *Productus* and *Ceratites* limestones. The former is believed to belong to the Upper Carboniferous and Permian, the latter to the Trias. Jurassic beds are found only in the western portion of the range.

Climate.—Because of its subtropical position, scanty rainfall and cloudless skies and the wide expanse of untilled plains, the climate of the Punjab presents greater extremes of both heat and cold than any other part of India. From the middle of April to the middle of September it is extremely hot, while from the beginning of October to the end of March there is a magnificent cool season, resembling that of the Mediterranean Riviera, with warm bright days and cool nights. Frosts are frequent in January. In the first months of the hot season, till the end of June, a dry heat is experienced, with a temperature rising to 120° F. in the shade. At the end of June the monsoon arrives, the rains break in the east of the Punjab and though the heat is less intense the air is moist; and from the middle of August the temperature gradually falls. This is the most unhealthful period of the year, being exceedingly malarious. The Punjab enjoys two well-marked seasons of rainfall: the monsoon period, lasting from the middle of June till the end of September, on which the autumn crops and spring sowings depend; and the winter rains, which fall early in January and, though often insignificant in amount, materially affect the prosperity of the spring harvest. Excepting in the Himalaya the rainfall is greatest in the east, as the Bombay monsoon is exhausted in its passage over the great plains of Sind and Rajpu-

tana, while the west winds from Baluchistan pass over an arid tract and leave such moisture as they may have collected on the western slopes of the Suliman range; so that the Punjab depends for its rain very largely on the southeast winds from the Bay of Bengal. The submontane tract has an annual average of 36 to 32 in., the eastern plains vary from 20 to 14 in. and the western plains from 10 to 5 in. (E. D. MacL.; E. Hd.)

History.—The history of the Punjab has been profoundly influenced by the fact that between Peshawar and Dera Ismail Khan the four frontier passes of the Khyber, Kurram, Tochi and Gomal serve as gateways from Afghanistan to the Punjab plains. For this reason it is ethnologically more closely related to central Asia than to India. Until 1922 no structural remains in India could be assigned with certainty to a period earlier than the 3rd century B.C.; later, excavations at Harappa and Mohenjo-Daro unearthed the remains of a civilization 5,000 years old bearing a general resemblance to that of Elam and Mesopotamia (*see* India: *History*). The first migration of which there is any evidence, however, is that of the Indo-European (Aryan) peoples who entered the Punjab in prehistoric times. Centuries later, within historical times, successive waves of other invaders swept through the frontier passes; and all these migrations and invasions added to the heterogeneity of the population.

The exact limits of the Achaemenian empire of Darius I cannot be determined, but it probably included the Indus valley and parts of the Punjab. The earliest date known for certain in Indian history is Alexander the Great's invasion of the Punjab in 326 B.C. After defeating Porus, the Indian ruler of the territories between the Hydaspes (Jhelum) and the Acesines (Chenab), Alexander advanced to the Hyphasis (Beas), beyond which his troops refused to march. Having crushed the power of the Cathaei, Malli and Oxydracae between the Acesines and the Zaradrus (Sutlej), he retired through Gedrosia (Baluchistan). His invasion was merely a large-scale raid and his death in 323 prevented the consolidation of his power in the Punjab and the Indus valley. The history of northern India proves that the mountain barrier of the northwestern frontier seldom formed a political boundary, for the kingdoms of the Persians, Mauryas, Graeco-Bactrians, Sakas, Parthians, Kushans and Ephthalites extended from Afghanistan to the Punjab plains.

The first Moslems to penetrate into northern India were the Arabs who, in A.D. 713, extended their power to the lower Punjab; but the Moslem conquest of the Punjab was the work of Mahmud of Ghazni, who overthrew the Hindushahiya dynasty ruling between Lamaghan and the Chenab and annexed their territories to his extensive central Asian empire. The Punjab remained in Ghaznevid hands until Mahmud's descendants were expelled by Mohammed of Ghur in 1186. It formed part of the sultanate of Delhi from 1206 until Baber's defeat of Ibrahim Lodi at Panipat in 1526 paved the way for the foundation of the Mogul empire, of which it remained a part until disintegration set in during the first half of the 18th century.

The religious intolerance of the Mogul emperors after the death of Akbar in 1605 led to the growth of Sikh political power in the Punjab and transformed a religious sect, founded by Guru Nanak in the second half of the 15th century, into a military organization animated with undying hatred toward Moslems. The weakness of the emperors who succeeded Aurangzeb facilitated the growth of Maratha power. From 1720 onward the Maratha peshwas adopted a policy of territorial aggrandizement and, by 1758, had overrun almost the whole of northern India as far as Peshawar. They were gradually driven southward by the Afghans under Ahmad Shah Durrani to Panipat, where they were routed with enormous losses on Jan. 14, 1761. After the death of Ahmad Shah the various Sikh groups or *misls* began to consolidate their power in the Punjab. The most important of these *misls* were the Bhangis of Gujrat, Sialkot, Lahore and Amritsar; the Ahluwalias of Kapurthala, Jullundur and Hoshiarpur; and the Kanhyas of Gurdaspur. From 1790 onward, Ranjit Singh, the head of the Sukarchakia *misl*, rose to prominence as leader of the Sikh resistance to the Afghan ruler Zaman Shah. His attempt to establish his authority over his coreligionists, the cis-Sutlejian Sikhs, brought him into contact with the British, who had extended their power to the Jumna; and an agreement was formed in 1809 by which the Sikh ruler accepted the Sutlej as his frontier. From this date his power increased rapidly. Between 1813 and 1821 he annexed Attock, Kashmir, Dera Ghazi Khan and Dera Ismail Khan. It was not until 1834, however, that Peshawar came under Sikh control

After the death of Ranjit Singh in 1839 the Punjab became the scene of widespread lawlessness, and power passed to the army of the Sikh Khalsa. Suspecting the British of contemplating annexation and eager for war, the Sikhs in 1845 invaded British territory but were defeated in desperate struggles at Moodkee, Ferozeshah, Aliwal and Sobraon. By a treaty in 1846 they were compelled to surrender all lands on the British side of the Sutlej together with the Jullundur Doab, to pay an indemnity and to limit the strength of their armed forces. The young maharaja, Dalip Singh, was to be guided by a council of regency presided over by Sir Henry Lawrence. The new arrangements did not prove acceptable to the Sikhs, and war broke out once more in 1848. After the battles of Chillianwalla and Gujrat the Punjab was annexed to British India on April 2, 1849. (*See* Sikh Wars.)

The newly conquered territories were placed under a board of administration until 1853, when the board's powers and functions were vested in a chief commissioner. Six years later the Punjab and its dependencies were formed into a lieutenant-governorship. The annexation of the Punjab, by advancing the British administrative boundary across the Indus, brought the government of India into closer contact with the Pathan tribes of the northwestern frontier. Until 1876 relations with the tribesmen were conducted by the deputy commissioners of Hazara, Peshawar, Kohat, Bannu, Dera Ismail Khan and Dera Ghazi Khan. The system of political agencies was not adopted until 1878, when a special officer was appointed for the Khyber. The Kurram, Malakand, Tochi and Wana agencies were created between 1892 and 1896. The tribes remained under the control of the Punjab government until the creation of the North-West Frontier province in 1901. In 1912 Delhi, previously included in the Punjab, was formed into a separate province.

The response of the Punjab during World War I was magnificent: of the 1,302,000 combatants recruited throughout British India, 300,000 were provided by the Punjab, of whom more than one-half were Moslems. In the postwar years communal relations in the province were embittered by the activities of the *tanzim* and *tabligh* movements organized by Moslems to combat the proselytizing of the Hindu *shuddi*. Far more serious than this communal strife were the political disturbances culminating in the Jallianwalla Bagh incident of 1919. (For the Punjab rebellion of 1919 *see* India: *History*.)

In 1921 the Punjab was raised to the status of a governor's province. From 1922 until the passing of the Sikh Shrines act, 1925, the peace was disturbed by the Akali Sikhs who wished to devote the revenues of certain shrines and temples to the spiritual benefit of the Sikh community.

The separation of Pakistan from India in 1947 was followed by the division of the Punjab into the two provinces of East and West Punjab with Hindu and Moslem majorities respectively. The boundary was delimited in Aug. 1947 by Sir Cyril Radcliffe. (C. C. D.)

Minerals.—Besides rock salt, the mineral products of the Punjab are not many. Limestone, good for building, is obtained at Chiniot on the Chenab and elsewhere. There are extensive alum beds at Kalabagh on the Indus. A small quantity of coal is found in the Salt range in disconnected beds. Petroleum is found in small quantities at a number of places in Rawalpindi and extracted by a company. In almost all parts of the Punjab there is kunkur, rough nodular limestone, commonly found in thick beds, a few feet below the ground, used for road metal and burned for lime.

Agriculture and Forestry.—As in other parts of India, there are commonly two harvests in the year. The spring crops are wheat, barley, gram, various vegetables, oilseeds and tobacco; the autumn crops are rice, millets, maize, pulse, cotton, indigo and sugar cane. Wheat has become the most important export. In the spring of 1938 an area of 11,500,000 ac. was harvested, producing 4,500,000 tons. Tea is cultivated in Kangra district. Potatoes are grown extensively on cleared areas on the hills. The Punjab produces freely many of the Indian fruits. Grapes are grown in many of the Himalayan valleys where the rain is not excessive; but they are inferior to those brought from Kabul.

The forest area of the Punjab consists of 6,251 sq.mi. of which 1,682 sq.mi. are preserved and 3,270 sq.mi. protected. The principal reserved forests are the deodar (*Cedrus deodara*) and chil (*Pinus longifolia*) tracts in the hills, the plantations of shisham (*Dalbergia sissu*) and sal (*Shorea robusta*) in the plains and the fuel rakhs or preserves (*Acacia, Prosopis,* etc.).

Manufactures and Trade.—Most of the indigenous manufactures of the Punjab are those common to most other parts of the subcontinent. Among others are woollen fabrics, carpets and shawls, silk cloths and embroidery, jewellery, ornamental metalwork, wood and ivory carving, turned and lacquered woodwork, glazed pottery, arms and armour and musical instruments. Some of these are represented by work of special kinds or special excellence, notably the silk fabrics of Multan and Bahawalpur; the carpets of Lahore and Amritsar; the kashi or glazed tilework (an ancient art still practised in a few places);

koftgari, inlaid metal work (gold wire on steel), chiefly made at Gujrat and Sialkot; shawls and other fine woollen fabrics, made by Kashmiri workpeople at Ludhiana and Nurpur, as well as in Kashmir; silk embroidery for shawls, scarfs and turbans, at Delhi, Lahore and Multan; embroidery on cloth for elephant trappings, bed and table covers, etc., at Lahore and Multan; enamelled ornaments, in Kangra and Multan; quill embroidery on leather, in Kangra and Simla; lacquered woodwork, at Pak Pattan. Cotton weaving gives employment to about 1,000,000 persons, but the most flourishing industry is the woollen factories of Amritsar, Gurdaspur and elsewhere.

The trade of the Punjab is almost wholly dependent upon agriculture. In a normal year the principal feature of the trade is the movement of wheat to Karachi, which is the natural port for the country. But in a bad season, when the rains fail, this movement is at once checked, the wheat is held up in reserve and an eastward movement in cheaper grains begins. The other chief articles of export are pulse and raw cotton. The Punjab has a transfrontier trade with Kashmir, Ladakh, Yarkand and Tibet on the north and with Afghanistan on the west.

Canals.—Irrigation for large areas is from canals and from reservoirs, and for smaller areas from wells. The canals are of two kinds: those carrying a permanent stream throughout the year, and those which fill only on the periodical rising of the rivers, the latter being known as "inundation canals." A few parts of the country present facilities for forming reservoirs, by closing the narrow outlets of small valleys and storing the accumulated rainfall. The canal system is among the finest in the world.

The old canals of Mogul days were improved or reconstructed by the British administration and are represented by the Western Jumna and Bari Doab canal. These were followed by the Sirhind canal (1883) and by the two great Colony canals, the Lower Chenab and Lower Jhelum (1892–1901). Then came the Triple Canal scheme (1912–15, comprising the Upper Jhelum, Upper Chenab and Lower Bari Doab canals), and the Sutlej valley canals (1933). Nine colonies had sprung up in these canal areas. The total length of the West Punjab canal system was 12,183 mi. in 1949, irrigating an area of 9,591,709 ac. In 1947 the Thal project was completed, at a cost of £150,000, to serve the West Punjab. The barrage stands at Daud Khel near the Indus. The area irrigated by it is 350,000 ac. in the districts of Mianwali and Shahpur. Waterlogging was attacked by lining the canals with concrete. In the East Punjab (India) the area irrigated by government works is 3,671,924 ac., the value of crops estimated in 1945–46 being more than £25,000,000. The total capital outlay in East Punjab irrigation was about £6,000,000, the revenue amounting to about £1,000,000 or 14.9% on the capital outlay. Among the important canal projects started before partition was the Bhakra dam in Bilaspur, involving the construction of a dam 670 ft. high on the Sutlej, near the village of Bhakra, 50 mi. upstream of Rupar, to irrigate 3,500,000 ac. annually, and to generate 250,000 kw. of power. Eight miles away, Nangal dam was planned to divert supplies from the Sutlej for the Nangal Hydel canal and to provide eventually 140,000 kw. The total cost of the Bhakra-Nangal project was estimated at nearly £100,000,000. When conceived, the Bhakra project was intended to serve the whole of undivided Punjab, so that the distribution of water became an issue of some difficulty as between Pakistan and India; but a joint committee of experts from both countries was composed to ensure an amicable settlement.

Railways.—The Punjab is well supplied with railways. Before partition the North-Western railway system, with headquarters at Lahore, had the largest mileage of any in the subcontinent. On partition the Indian portion of the North-Western railway was constituted into the Eastern Punjab railway, with a length of 1,855.25 mi., leaving 5,026 mi. to Pakistan, which retained the name of North-Western railway for the system and also the headquarters at Lahore.

Administration.—The British province of the Punjab up to 1947 had an autonomous government under the government of India act, 1935. The legislature consisted of 175 members, to whom the ministry was responsible, the governor ruling as a constitutional representative of the king emperor. After partition the legislature was split according to the territorial changes; and two legislatures were consequently created, for East Punjab and West Punjab, the two governors being heads of the two provinces. When India became a republic in 1950, the governor of the East Punjab became the representative of the president, but the governor of the West Punjab remained the representative of the king. The Government of India act was provisionally adapted as a constitution for each of these provinces until India's own constitution was adopted in 1950. The general elections of 1951 for the West Punjab, when the Moslem league returned to power with a large majority, were based on adult suffrage (the first time such adult suffrage had been actively applied in any election in the subcontinent); but only 30% polled. Lahore is the capital of West Punjab; Jullundur was the capital of the East Punjab pending the construction of a new capital city at Chandigarh, 20 mi. from Umballa.

Education.—The Punjab university, founded in 1882, had served the whole of the Punjab, the Kashmir state as well as the undivided province. After partition the Khalsa college at Amritsar was transferred to the control of the education department of the East Punjab, and the Punjab university at Lahore remained in Pakistan. The West Punjab at mid-century had 29 colleges for men and 5 for women; 193 high schools (one-fifth of them for girls); 1,844 secondary schools (one-tenth for girls); and 6,843 primary schools (more than one-third of them for girls). Plans moreover were made for a university at Peshawar for the North-West Frontier province. In the East Punjab the government maintained 7 arts colleges (including 2 for women); 2 training colleges (one for men and the other for women); 7 "normal" schools (*i.e.*, schools in which teachers under training practice; 1 for men and 6 for women); 75 secondary schools, for boys and girls; and many centres for vocational training. A higher-grade medical college at Ludhiana was established by missionary enterprise; also 25 technical schools for boys and girls. There were 2,429 primary schools for boys and 817 for girls in 1950–51, the enrolments being nearly 300,000 and 67,000 respectively. Compulsory primary education applied to 37 towns and to 1,420 villages for boys only. (E. D. MACL.; E. HD.)

PUNO, a southeastern department of Peru. It includes the shores of Lake Titicaca, the high plateau on which the lake is situated, together with the mountains west, north and east enclosing the plateau. It also includes the headwaters of several tributaries of the Madre de Dios river east of the eastern cordillera and draining into the Amazon. Puno has an area of 26,133 sq.mi.; population (1950) 768,384. Connection is by the Southern railway with Cuzco, 240 mi. to the north, also with the Pacific port of Mollendo and by steamer (across Lake Titicaca) and railway to La Paz, Bolivia. A projected section of the Pan American highway will eventually traverse the department.

Around the shores of the lake (12,507 ft. above sea level) the plateau is cultivated and well settled, but the altitude is so great that only potatoes, barley and a few other cereals will mature. The department of Puno produces about 70% of all the gold of Peru. It comes chiefly from the mountain provinces of Sandia and Carabaya. Coal, salt, copper, antimony, tin, quicksilver, zinc, marble and cobalt are also found. The manufacturing of woollen goods is important and in the province of Lampa there is a considerable manufacture of pottery.

The city of Puno (pop. 19,603 in 1950), capital of the department and of the province of Puno, is located on the shore of Lake Titicaca at the lake terminus of rail lines to Arequipa (219 mi.) and its Pacific ports of Mollendo and Matarani and to Cuzco, 240 mi. to the north. There is also regular steamer service from Puno across Lake Titicaca to Guaqui, Bolivia, with a rail connection thence to La Paz.

PUNTARENAS or PUNTA ARENAS, a seaport and capital of the province of Puntarenas, Costa Rica; on the Gulf of Nicoya, an inlet of the Pacific ocean, and at the western terminus of the interoceanic railway from Limón. Pop. (1950) town, 11,611; province, 88,168. Puntarenas is the principal harbour of Costa Rica on the Pacific, and a port of call for the United States liners which ply between San Francisco, Calif., and Panamá. It has a growing export trade in coffee and bananas. The district of Puntarenas comprises the entire littoral from Burica point to the Río de las Lajas, an effluent of the Gulf of Nicoya.

PUNXSUTAWNEY, a borough of Jefferson county, Pa., U.S., 70 mi. N.E. of Pittsburgh; served by the Buffalo, Rochester and Pittsburgh and the Pennsylvania railways. Pop. (1950) 8,969. It is a trading centre for agriculture, surrounded by coal operations and gas fields. Punxsutawney was founded about 1812 and incorporated in 1845.

PUPIN, MICHAEL IDVORSKY (1858–1935), U.S. inventor, was born in Idvor, Hung. (now in Yugoslavia), Oct. 4, 1858. He went to the U.S. in 1874, graduating from Columbia university, 1883. The first to hold the John Tyndall fellowship (1886–88), he later studied physics and mathematics at Cambridge university and under H. von Helmholtz at the university of Berlin (Ph.D., 1889). He was instructor in mathematical physics at Columbia, 1890; and was appointed adjunct professor of mechanics, 1892, becoming professor of electromechanics there in 1901 and later director of the Phoenix research laboratories.

By means of inductance coils placed at predetermined intervals of the transmitting wire, he greatly extended the range of long-distance telephony, particularly over telephone cables. The patent for this invention was acquired in 1901 by the Bell Telephone company and by German telephone interests. He has made several other inventions in electrical wave propagation, electrical resonance and multiplex telegraphy. He discovered secondary X-ray radiation in 1896 and invented in the same year means for short exposure X-ray photography by the interposition of a fluorescent screen. He wrote *From Immigrant to Inventor*.

PUPPIS, one of the three southern constellations into which the large Ptolemaic constellation Argo (*q.v.*) was subdivided (*puppis:* poop). The bright new star Nova Puppis was visible during the winter of 1942.

PUQUINAN, a group of tribes of South American Indians, doubtfully constituting an independent linguistic stock. Their identity with the modern Uros has been much discussed. The area occupied (if this identity be accepted) would include the whole basin of lakes Titicaca and Poöpo, and the Salar de Uyuni in the Bolivian plateau, together with the Peruvian-Chilean coast from about 16° to 22° S. lat. Within this area they lived in scattered small groups among the Aymaran (*q.v.*) tribes. Rivet thinks that the Puquinan language (together with the Uro) is in reality a member of the Arawakan (*q.v.*) stock and that this whole group of Puquinan and Uran tribes represents a very ancient intrusion westward of the Arawakan peoples.

See G. de Crequi-Montfort and P. Rivet, "La Langue Uru ou Puquina" (*J. Soc. Américanistes de Paris* [n.s.], xvii: 211–244; xviii: 111–139, with bibliography).

PURCELL, HENRY (1659–1695), English composer, was born in Westminster. His recent biographer, Dennis Arundell, points out that the statement *aet. suae. 24* on the printed edition of his *Sonatas* in June 1683 places his birth between June and November 1659, Nov. 20, 1695, being the date of his death in his 37th year. His father Henry Purcell, or Pursell, was a gentleman of the chapel royal, whose eldest son Edward (1653–1717) became gentleman usher to Charles II, and afterward distinguished himself in the army, while Henry and Daniel, the two younger sons, became musicians. On his father's death in 1664, Henry Purcell was placed under the guardianship of his uncle Thomas Purcell (d. 1682), also a gentleman of the chapel and a man of extraordinary probity and kindness. Both he and Henry Purcell the elder sang at the coronation of Charles II. Through his uncle's interest Purcell was admitted as a chorister of the chapel and was placed under Capt. Henry Cooke (d. 1672), master of the children, an excellent teacher and a composer of anthems, to whom Samuel Pepys makes a number of references in his *Diary*. On Cooke's death Pelham Humfrey (1647–74) became master, and he again was an excellent teacher as well as a musician of genius; but as a pupil of Lully he naturally stood for the French school, and in this respect failed to influence Purcell, who took the Italian masters for his models.

Purcell's third and last master was the distinguished composer and organist Dr. John Blow (1648–1708), to whom Purcell's great indebtedness is not always sufficiently realized. In 1673, when his voice broke, Purcell was dismissed with an ex-chorister's salary of £30 a year and presented with certain articles of dress. He was also given the appointment of (unpaid) assistant to John Kingston, keeper of the king's instruments, together with a promise to succeed him. In 1677 he was appointed "composer in ordinary for the violin" in succession to Matthew Lock. Purcell had been copyist at Westminster abbey since 1677, and in 1680 he succeeded Dr. Blow as organist.

The year 1680 was the beginning of a period of great productivity. In it he wrote the music to Nathaniel Lee's *Theodosius,* the first of a long series of dramas for which he provided incidental music, and one in which an introductory ritual scene gave him unusual scope; this was followed by Thomas D'Urfey's *Virtuous Wife.* He also produced the first of his court odes or "Welcome Songs" at this date and wrote several anthems, many of which were composed especially for the prodigious basso profondo of the Rev. John Gostling (or Gosling), a singer at Canterbury and later at the chapel royal, to whom John Evelyn alludes as "that stupendous bass." Either in 1680 or the following year he married Frances Peters, and in 1682 his eldest son was born. From 1682 he held the post of organist to the chapel conjointly with his appointment at the abbey. His first printed composition was the 12 *Sonnatas of III Parts: two violins and basse: to the organ or harpsichord.* These, though avowedly based on Italian models, show great power and originality. Purcell had now become "composer in ordinary to the king" and his official life was a very full one. For each public event he composed an ode or an anthem: some of the finest of these are the ode "Swifter, Isis, Swifter Flow" (1681); the "St. Cecilia" odes; the "Fly, Bold Rebellion" (in celebration of the suppression of the Rye House Plot, 1683); two anthems written for James II's coronation: "O I Was Glad" and "My Heart is Inditing." The *Te Deum and Jubilate,* written for St. Cecilia's Day 1694, was notable as being the first English anthem with orchestral accompaniment. It was performed annually at St. Paul's cathedral until 1712 and in alternate years with G. F. Handel's Utrecht *Te Deum* until 1743. In all his anthems there is a large proportion of instrumental music.

The opera *Dido and Aeneas,* which above all Purcell's works inspires admiration and affection in an equal degree, was written to a libretto furnished by Nahum Tate at the request of Josiah Priest, a dancing master who also kept a boarding school for young gentlewomen, first in Leicester Fields and afterward at Chelsea. The date of its composition and original performance at the school has been fixed by W. Barclay Squire of the British museum as about the year 1689. In this work there is no spoken dialogue, but only recitative, and it is characterized from beginning to end by the dramatic directness which Purcell possessed in so high a degree. Dido's exquisite song of farewell is one of the flawless things in music, classical in form and in its dignified restraint, and yet of rare emotional quality. As is so often the case when he has some poignant emotion to express, Purcell chooses here to build up the song on a "ground," and the relentless reiteration of the bass contributes greatly to the dramatic effect. Graceful dance choruses, lumbering sailor dances and witches' incantations relieve the tragedy, and, avoiding an anti-climax after Dido's farewell, the composer ends with a soft and tenderly expressive chorus, "With drooping wings, ye Cupids, come," in which music and words achieve perfect union.

Although *Dido and Aeneas* stands out today as an isolated phenomenon in the age in which it is written, it was rather the peak of a movement in which Purcell's predecessors did valuable experimental work; and here, again, Blow's influence is seen, for in his only known dramatic work, *Venus and Adonis,* he sets the example of having every word sung and none spoken. He is no doubt also partly responsible for Purcell's skill in the use of a ground, and he probably encouraged, rather than discouraged, his pupil's audacities of harmony, since he himself was a notorious offender. Among the peculiarities of Purcell's idiom are the constant false relations and the use of the descending melodic minor in ascending passages, and vice versa. He had a marked preference for the flat minor keys. His fine feeling for rhythm, form and climax invests even his smaller pieces with a quality that is unmistakable. In judging Purcell's scores it should be remembered that he was practically restricted to oboes and trumpets as regards wind instruments, since even the modern flute had not come into use in his time.

In 1690 Purcell wrote the music to Betterton's *Dioclesian,* which includes a masque. He was associated with Dryden in *Tyrannic Love* (1687), *Amphitryon* (1690) and *King Arthur* (1691), in all of which the music consists of separate numbers which form no integral part of the drama. In *King Arthur,* Josiah Priest was responsible for the dances. This play, which contains the famous song "Fairest Isle," had a great success and was revived on various occasions up to 1803, and once in 1842. It was first published in 1843 by the Musical Antiquarian society. The score of Purcell's songs and music to *The Fairy Queen* (an adaptation of William Shakespeare's *A Midsummer Night's Dream*) written in 1693 was discovered in 1901 and edited for the Purcell society by J. S. Shedlock in 1903.

Purcell suffered much at the hands of his editors until, in 1876, the Purcell society was founded for the purpose of bringing out a complete and authoritative edition of his works, the majority of which were still in manuscript. There are signs of the beginning of a great Purcell revival, not only in England but also on the continent, where performances of *Dido and Aeneas* in Vienna, Münster and Basle aroused enthusiasm and interest.

Purcell died at his house in Dean's Yard, Westminster, on Nov. 21, 1695, and was buried in Westminster abbey on Nov. 26. He left a widow and three children, three others having died before him. His widow died in 1706. In 1682 and 1702 she published *Orpheus Britannicus,* a collection of his works, in two parts. A famous portrait of the composer is that by Sir Godfrey Kneller, bequeathed to the National Portrait gallery, London, by Barclay Squire. There is also an engraved portrait by R. White on the first edition of his sonatas (1683).

Other dramatic works by Purcell were *Don Quixote, The Indian Queen* and *Bon duca* (all in 1695) and many earlier works. Smaller works are the fantasias and sonatas for three or more parts, the suites and many miscellaneous pieces for harpsichord, and songs. For a complete list, *see* Grove's *Dictionary* and the publications of the Purcell society. Other publications include the *Chacony* for string quartet (Chester Ltd. 1926); *Dido and Aeneas* with Eng. and German text, ed. by E. J. Dent, and Dennis Arundell's life, *Henry Purcell* (both by the Oxford University Press, 1928); Henri Dupré, *Purcell* (Eng. trans., Knopf, New York and London, 1929); the life by Dr. W. Cummings in the *Great Musicians* series (1903) remains a standard work.

PURCHAS, SAMUEL (1575?–1626), English compiler of works on travel and discovery, was born at Thaxted, Essex, and studied at St. John's college, Cambridge, and at Oxford. In 1604 he was presented by James I to the vicarage of Eastwood, Essex, and in 1614 became chaplain to Archbishop Abbot and rector of St. Martin's, Ludgate, London. Purchas died in Sept. or Oct. 1626, according to some in a debtors' prison. As an editor and compiler he was often injudicious, careless and even unfaithful; but his collections are often the only sources of information upon questions affecting the history of exploration. His works include: *Purchas, His Pilgrimage; or, Relations of the World and the Religions Observed in All Ages* (1616); *Purchas, His Pilgrim. Microcosmus, or the Histories of Man. Relating the Wonders of His Generation, Vanities in His Degeneration, Necessity of His Regeneration* (1619); *Hakluytus Posthumus or Purchas His Pilgrimes, Contayning a History of the World in Sea Voyages and Lande Travells, by Englishmen and Others* (4 vols., 1625).

PURCHASE, in its common sense, that which is acquired by the payment of money or its equivalent. The term was early used by the lawyers (*e.g.,* Britton, in 1292) for the acquirement of property by means other than inheritance or mere act of law, including acquirement by escheat, prescription, occupancy, alienation and forfeiture; more generally, purchase in law means acquisition of land by bargain or sale, according to the law of "vendor and purchaser." (*See* Laws Relating to Real Property and Conveyancing.) A later meaning is the mechanical contrivance by which power can be used, a hold or fulcrum. This first appears (16th century) in the nautical use of the verb, to haul up a rope or cable; that is, to "gain" advantage over the rope bit by bit.

PURDAH, the curtain which screens women from the sight of men in Eastern countries; a *purdah-nashin* is a woman who sits behind the curtain (Pers. *parda*). In Anglo-Indian usage, to "lift the purdah" means to reveal a secret.

PURE LINE. A pure line consists of a self-fertilized individual and its progeny; it is a group of individuals all possessing the same hereditary constitution, in which all the factors are present in duplicate. Until W. L. Johannsen studied the effects of selection on the weights of individual seeds of the Princess bean there was no general explanation of the manner in which this process operates (*see* Breeds and Breeding; Inbreeding; Animal Breeding; Genetics; Heredity; Mendelism and Selection: *Artificial Selection*). *See* W. Johannsen, *Ueber Erblichkeit in Populationen und in reinen Linien* (1903).

PURGATORY, according to Roman Catholic faith, a state of suffering after death in which the souls of those who die in venial sin, and of those who still owe some debt of temporal punishment for mortal sin, are rendered fit to enter heaven. It is believed that such souls continue to be members of the church of Christ; that they are helped by the suffrages of the living—that is, by prayers, alms and other good works, and more especially by the sacrifice of the mass; and that, although delayed until "the last farthing is paid," their salvation is assured. Catholics support this doctrine chiefly by reference to the Jewish belief in the efficacy of prayer for the dead (2 Macc., xii, 42 *seq.*), the tradition of the early Christians and the authority of the church.

The state of purgatory is usually thought of as having some position in space, and as being distinct from heaven and hell; but any theory as to its exact latitude and longitude, such as underlies Dante Alighieri's description, must be regarded as imaginative. Most theologians since Thomas Aquinas and Bonaventura have taught that the souls in purgatory are tormented by material fire, but the Greeks have never accepted this opinion. It must be inferred from the whole practice of indulgences as at present authorized that the pains of purgatory are measurable by years and days; but here also everything is indefinite. The council of Trent, while it commands all bishops to teach "the sound doctrine of purgatory handed down by the venerable fathers and sacred councils," bids them exclude from popular addresses all the "more difficult and subtle questions relating to the subject which do not tend to edification."

The Eastern Church affirms belief in an intermediate state after death, but the belief is otherwise as vague as the expressions of the pre-Nicene fathers on the subject. The Longer Catechism of the Orthodox Church (Q. 376) states:

"Such souls as have departed with faith but without having had time to bring forth fruits meet for repentance may be aided towards the attainment of a blessed resurrection by prayers offered in their behalf, especially such as are offered in union with the oblation of the bloodless sacrifice of the Body and Blood of Christ, and by works of mercy done in faith for their memory."

The efficacy of prayers for the dead, and indirectly the doctrine of purgatory, were denied by early Gnostic sects, by Aëtius in the 4th century and by the Waldenses, Cathari, Albigenses and Lollards in the middle ages. Protestants, with the exception of a small minority in the Anglican communion, unanimously reject the doctrine of purgatory and affirm that "the souls of believers are at their death made perfect in holiness and do immediately pass into glory." Rejection of an intermediate state after death follows the Protestant idea of justification by faith as logically as the doctrine of purgatory results from the Catholic idea of justification by works.

An analogy to purgatory can be traced in most religions. Zoroaster conducts souls through 12 stages before they are sufficiently purified to enter heaven; and the Stoics conceived of a middle place of enlightenment which they called ἐμπύρωσις.

Bibliography.—The principal authoritative statements of the Catholic Church on the doctrine of purgatory were made at the council of Florence (*Decret. unionis*), and at that of Trent (Sess. vi. can. 30; Sess. xxii, c. 2, can. 3; Sess. xxv). *See* H. J. D. Denziger's *Enchiridion;* J. Bautz, *Das Fegfeuer* (Mainz, 1883) and L. Redner, *Das Fegfeuer* (Regensburg, 1856). An elaborate treatise from the Catholic standpoint is that of Cardinal Bellarmine, *De purgatorio.* The subject is discussed, moreover, in all major works on dogmatic theology. There is a representative Catholic statement in the *Catholic Encyclopaedia,* and a Protestant presentation by Rud. Hoffmann in Herzog-Hauck's *Realencyklopädie,* 3rd ed., vol. v, pp. 788–792.

PURI or **JAGANNATH,** a town and district of British India, in the province of Orissa. The town is on the seacoast, and has a railway station. Pop. (1941) 41,055. Since it contains the world-famous shrine of Jagannath (*see* Juggernaut), Puri is perhaps the most frequented of all Hindu places of pilgrimage; of recent years also it has won some popularity as a seaside health resort. The great temple of Jagannath was built in the 12th century by Choda Ganga, the greatest of the eastern Ganga kings of Kalinganagara (Ganjam).

The District of Puri has an area of 2,451 sq.mi. and a population (1941) of 1,101,939. Most of the country is flat. The middle and eastern divisions of the district, forming the southwestern part of the Mahanadi delta, consist entirely of alluvial

plains, watered by a network of channels through which the most southerly branch of that river, the Koyakhai, finds its way into the sea. The other rivers are the Bhargavi, the Daya and the Nun, all of which flow into the Chilka lake. During the rainy season the rivers come down in floods, sometimes bursting their banks and carrying everything before them. The Chilka lake is one of the largest in India; its length is 44 m., and its mean breadth 13 m. in the north and 5 m. in the south. It is separated from the sea only by a narrow strip of sand. The lake is saline and everywhere very shallow, its mean depth ranging from 3 to 5 feet.

Puri first came under the British in 1803. Later events were the rebellion of the maharaja of Khurda in 1804 and the rising of the *paiks* or peasant militia in 1817–18. In the Orissa famine of 1866 more than one-third of the population is said to have perished. The district is served by the Bengal Nagpur railway which was opened throughout from Calcutta to Madras in 1891, with a branch to Puri town.

Puri district is rich in historical remains, from rock-hewn caves to the magnificent mediaeval shrines at Bhubaneswar and Konarak. On a hill at Dhauli, 4 m. S.W. of Bhubaneswar, are rocks with edicts inscribed by Asoka in the 3rd century B.C. and an elephant carved out of the solid rock, the oldest carving of an elephant known in India. In the hills of Udayagiri and Khandagiri are Jaina caves hewn out of the rock, and some (such as the Rani Gumpha or queen's palace) profusely carved, between the 3rd and 1st centuries B.C. The greatest architectural glory of the district is its collection of temples built between the 8th and 13th centuries A.D. Bhubaneswar is crowded with Saiva shrines of which the largest is the Lingaraj, while the Raja Rani temple has been described by Fergusson as one of the gems of Orissa art. More magnificent, even in its ruin, is the sun-god's temple of Konarak, of which Sir John Marshall writes: "There is no monument of Hinduism, I think, that is at once so stupendous and so perfectly proportioned."

PURIFICATION. Purification denotes the processes employed to prepare individuals or communities for contact with persons or things otherwise dangerous, or to prevent the consequences of contact with such persons or things. To deal first with the latter aspect, a man may unwittingly violate a tabu and such is the sense of social solidarity that the whole community feels itself menaced with calamity. He must be purified. The society must be protected. All conditions of diminished social activity on the part of an individual are dangerous. (*Andaman Islanders*, p. 303.) Thus, "among most or all African tribes a sin, wrong doing or breach of custom is not merely a matter demanding punishment or redress but it imparts a bane or evil influence which remains unless the necessary purification follows. The point to be emphasized is that this mysterious force affects not the evil-doer but the person injured, so that it is he who must be purified. For instance, a man who is wounded is purified by the one who wounded him." (C. Dundas, *Kilimanjaro and its People*, 1924, p. 155.) Contact with persons and things possessing this dangerous potency is often essential. In this sense cleanliness is very close to godliness. In general food is regarded as something that may only be approached with ritual precautions. (*Andaman Islanders*, p. 273.) The savage must come to his meals clean. Primitive communities insist on the purification of the successful warrior. (*Andaman Islanders*, p. 133; *Ila Speaking Peoples*, I., 179; *Akamba* 198, *see* note; *The Sema Nagas*, p. 175; and *42nd Annual Report, Bureau of American Ethnology*, p. 423.) The sacrificial priest must be purified before he touches the holy object. He must be purified again when the rite is over.

It is evident that the dangerous qualities whose effect has to be neutralized are in one aspect of a spiritual nature and that intention, motive, purpose are not essential elements. The automatic effect of a breach of the law gives strength to the social order since, where the results of sin may affect all or any of the members of the society it is the business and interest of each man to keep the law and to see that his neighbour keeps it.

Whenever and wherever sin has come to be viewed as a breach of a divine order, punished by the Divinity, a judge of the heart of man, a just judge, motives and purposes assume importance. Purification is here directed to the conscience. The preventive action of the rites of purification comes in course of time to include deep, permanent modifications of the personality of the sinner, so that he sins no more. Coercion comes from within and is self-determined. *See* Bibliography to article ANTHROPOLOGY.

PURIM, a Jewish festival on Adar 14 and 15, to commemorate the deliverance of the Jews from Haman, the minister of Ahasuerus (Artaxerxes?), as related in the book of Esther (lit. lots, Heb. פּוּר, Esther iii. 7; ix. 24, 26, possibly from Assyrian *puru*, stone or Vedic *pûrti*, portion): so called from the lots cast by Haman to determine an auspicious day for the massacre. The origin of the festival is much disputed: some hold that it developed from a primitive spring festival because (a) it is celebrated just before the advent of the New Year in *Nisṣan* and that the preliminary fasting was actually ordained in Esther iii. 7; iv. 16 for *Nisṣan*. But the fasting is a later institution (on this see *Jew. Enc.*, x. 278); (b) the feast is secular rather than religious: it has all the characteristics of a spring carnival including the ironical crowning of the buffoon-king or vegetation-god who was put to death after mockery (*cf.* Frazer, *Golden Bough*, ed. ii., vol. iii., pp. 154): S. Langdon (*Bab. Epic of Creation*, 1923, pp. 28, 33, etc.) traces a similar festival to Marduk (*cf.* Mordecai; Ishtar-Esther?) during *Nisṣan*, with the mystic ceremony of the death and resurrection of *Bêl*, from primitive times in Babylonia. Zimmern (*see* refs. in Langdon) drew a parallel with the leading features in the scourging and death of Jesus. But the Jewish beating of Haman or burning of his effigy is late and clearly borrowed from mediaeval carnival customs, probably in the 13th century. On the contrary, during the synagogal reading of the book of Esther the reader hurries over the execution of the ten sons of Haman (Esther ix. 7–10), pronouncing them in one breath. This goes back to the Talmud (Neg. 16 b) and is ordained (1) to denote their simultaneous death and (2) to avoid gloating over a fallen foe. If Purim were purely a Babylonian feast, the Jews of Palestine and Egypt would hardly have accepted or retained it long after their connection with the Persian Empire ceased, whereas Purim has always been most popular. (c) On the other hand, there are features in the Jewish liturgy which strongly suggest a secular origin and it is most likely that this festival, first secular and national, ultimately became sanctified and was made a religious occasion. The growth of this process may be traced in the service. The name of God is absent from the *Megillah* and various devices of the scribe make good the deficiency, *e.g.*, when the letters of the Tetragrammaton occur close together they are crowned or written large: in iv. 14 "another place" is interpreted of God because "place" (*Maqōm*) is used in this way. The only religious allusions in the book are iv. 16 and ix. 31. The scroll is called *'Iggereth* or letter (ix. 26 and 29) and the reader folds the scroll so as to make it resemble a letter and holds it aloft when he recites the word "letter" in the verses just named. This tends to mark the lower or secular category of the book, *i.e.*, it is classed as an "Epistle" rather than as a "Gospel." For the service itself *see* Singer's *Authorized Daily Prayer Book*, p. 276 (and p. ccvi. of *annotated ed.*), where the alphabetical poem (אַשְׁרֵי הָאִישׁ) may be noted.

A characteristic of Purim and the book of Esther often overlooked is its similarity to the Euripidean drama. A cardinal feature is the punishment of ὕβρις. Purim plays are frequent, by Christian (*e.g.*, Racine) as well as by Jewish authors.

PURINES. The purines comprise a large group of nitrogenous compounds, a few of which occur widely distributed throughout nature. They derive their name from the fact that they can be regarded as derived from one substance, purine itself. This name was coined by the German chemist, Emil Fischer, from the two Latin words *purum* and *uricum*, the latter being chosen

because the best known purine at that time, uric acid, occurs in urine. Fischer named this compound and pointed out its relation to known purines about 14 years before he actually prepared it in the laboratory.

Of the several hundred purines known, only 12 have been isolated from natural sources. All other purines are synthetic products and are only of academic interest. The following discussion will be limited almost entirely to eight of these purines which occur widely distributed throughout nature, namely, uric acid, guanine, adenine, xanthine, hypoxanthine, caffeine, theobromine and theophylline.

THE INDIVIDUAL PURINES

Uric Acid.—This was the first purine known, being discovered in human urinary calculi by the Swedish chemist Scheele in 1776. Scheele made careful investigations of its reactions and properties, these results being still used to identify uric acid. Thirty years later it was found that uric acid occurred in guano, and still later it was found that birds' excrement consisted largely of uric acid. Guano consists of the excrement of certain South American sea birds, which, with the help of a dry climate, has been accumulating for untold years. By far the best source of uric acid, however, is the excrement of serpents, which consists of over 95% of uric acid combined with small amounts of potassium and ammonia. It is only necessary to dissolve snakes' excrement in dilute alkali, filter, and reprecipitate with mineral acid.

Uric acid, however, occurs in other ways. As the mono-sodium salt it is the substance precipitated in body tissues in cases of gout, and is responsible for the formation of the gouty nodules with the subsequent inflammation and irritation which characterize this disease. Uric acid also occurs normally in the blood of man and other animals. In man the blood normally contains less than 0.1 mg. per cu. cm. Uric acid confines itself to the animal kingdom, although other purines are common as plant products.

The following table (Givens and Hunter) shows the variation in the relative amounts of allantoin, uric acid and bases (other purines) excreted in the urines of different species of mammals.

Order and Species.	*Allantoin*	*Uric acid*	*Nitrogen (%) present as Bases*
Marsupialia:			
Opossum	76.0	19.0	6.0
Rodentia:			
Guinea-pig	91.0	6.0	3.0
Rat	93.7	3.7	2.7
Ungulata:			
Sheep	64.0	16.0	20.0
Goat	81.0	7.0	12.0
Cow	92.1	7.3	0.7
Horse	88.0	12.0	0.5
Pig	92.3	1.8	5.8
Carnivora:			
Raccoon	92.6	5.4	2.0
Badger	96.9	1.9	1.2
Dog	97.1	1.9	1.3
Coyote	95.6	2.6	1.8
Primates:			
Monkey	66.0	8.0	26.0
Man	2.0	90.0	8.0

Man stands out as eliminating 90% of his purine-allantoin nitrogen in the form of uric acid, this proportion being 11 times as much as the monkey, which is biologically his closest relative. Too much importance must not be attached to the biological significance of this, however, as the ratio is known to vary considerably, even within a species.

The origin of uric acid as an excretory product has long been a matter of interest. According to A. P. Mathews (*Physiological Chemistry,* New York, 1915), the reason for the excretion of protein nitrogen in the form of uric acid rather than urea by birds and reptiles, is to be ascribed to their environment during evolution. The birds were evolved from the reptiles, and the reptiles were probably evolved in a dry, arid region, as indicated by other body characteristics. Urea is very soluble in water, and has a great affinity for it, whereas uric acid is insoluble, with no affinity for water, so that the excretion of nitrogen as uric acid rather than urea, saves much water for the organism, and would be an important adaptation in a region comparatively devoid of water.

In man the excreted uric acid may be divided into two varieties, the endogenous and the exogenous uric acid. The endogenous uric acid, about 0.4 grams a day, is very nearly constant for a given individual, but varies slightly in amount in different persons. It represents the uric acid which is formed in the body by synthesis and by the breakdown of nuclear tissue. On a diet which is free from purines, it is independent of the amount of fat, carbohydrate, protein or number of calories ingested. It is thought to originate from the oxidation of the hypoxanthine constantly formed in muscle and other tissues.

The exogenous uric acid is that formed by the oxidation of purines taken in as part of the food, chiefly in meat. All meat, and particularly glandular meat such as liver and sweetbreads, contains varying amounts of nucleic acid, which contains about 20% of the purines guanine and adenine. In the body these two substances are changed, by means of enzymes, into two other purines, xanthine and hypoxanthine, which are both oxidized to uric acid. The amount of exogenous uric acid depends, then, on the purine intake. Furthermore, it has repeatedly been shown that uric acid and other purines, injected hypodermically into the body, can be recovered nearly quantitatively in the urine.

Man excretes ingested purines almost entirely as uric acid, although other mammals excrete theirs almost entirely as allantoin, because the human body is lacking in a specific enzyme, uricase, which oxidizes uric acid to allantoin. The small amount of allantoin excreted by the human is probably preformed in the food. In the livers and other organs of animals which excrete allantoin, we find varying amounts of uricase, and if these organs are ground up and digested with uric acid, it is oxidized to allantoin. Different animals apparently differ in the efficiency with which this reaction is performed.

When the uric acid metabolism is disturbed, for reasons which are not as yet understood, the uric acid output in the urine is lowered. As the individual constantly ingests more purine, the result is that it is stored up. At first this storage takes place in the blood, but owing to the very low solubility of uric acid and its mono-sodium salt, only a limited amount can be held in this way. The excess crystallizes out, mainly in the cartilages and joints, as acid sodium urate, and the irritation resulting from these deposits is known as gout. It is evident that a gouty person should avoid foods which contain purines, such as meat, and confine his protein diet to such foods as milk and eggs, which are virtually purine free.

Guanine and Nucleic Acid.—Guanine, one of the two amino-purines occurring in nature, takes its name from the fact that it was discovered in guano, by B. Unger in 1845. Since that time, however, it has been found widely distributed throughout the animal and plant world. It occurs in the scales and skin of the bony fishes, and in the swim bladders, to which it gives their characteristic pearly appearance. It also is the chief constituent of the excrement of spiders. Human and pig urine contain small amounts of guanine. By far its most important occurrence, however, is in organs rich in cells, such as the pancreas, liver, spleen, testicles, etc., in animals, and in the germ cells of plants. It occurs here as a constant constituent of nucleic acid, of which it constitutes about 10%.

Nucleic acid, a compound occurring in the nuclei of all cells, is built up from four molecules of phosphoric acid, four of sugar, two of pyrimidines, and one each of guanine and adenine. When taken into the body as food, the guanine and adenine are eventually excreted as uric acid. These changes are brought about by the action of enzymes, which eventually break the nucleic acid up into its component molecules. The guanine is then changed by an enzyme, guanase, into its corresponding oxygen derivative, xanthine, which is then oxidized by an enzyme, xanthine oxidase, to uric acid.

It is an extremely interesting fact that in the pig the organs are entirely lacking in guanase; it is thus impossible for it to change guanine into allantoin, and consequently the pig frequently

suffers from a form of gout, similar in all respects to that in humans, except that the deposit in the joints consists of crystalline guanine instead of acid sodium urate.

Adenine.—Adenine and guanine are the only two amino-purines, and differ from one another by only one atom of oxygen, guanine being an oxidized adenine.

Adenine, discovered by A. Kossel in 1884 among the hydrolytic products of pancreatic nucleic acid, is found in all glandular tissues, which are rich in nucleins. In addition, it occurs free in the leaves of plants, for example tea leaves and alfalfa leaves. It has also been found combined with sugar in the blood stream.

Adenine, like guanine, is one of the chief contributors to the uric acid and allantoin output of mammals. After the enzymic cleavage of the nucleic acid there are two special enzymes to take care of the adenine. One of these, adenase, replaces the amino-group by an hydroxyl, giving hypoxanthine. Another enzyme, an oxidase, oxidizes the hypoxanthine to xanthine, which is further metabolized as in the case of guanine.

Xanthine.—This purine, first discovered by Marcet, in 1817, in a urinary stone, derives its name from the Greek word, *xanthos*, meaning yellow: when it is evaporated in a dish with HNO_3, a yellow spot remains. Xanthine occurs widely distributed in animal and plant matter, wherever guanine is found, being probably derived from guanine by enzymic and putrefactive processes.

Hypoxanthine (Sarcine).—Hypoxanthine is a reduced xanthine, which was discovered by Scherer in 1850 in an extract of spleen. In general, it may be found in all nuclear tissues, and is probably there as a decomposition product of adenine, from which it is derived by the substitution of an hydroxyl by an amino-group. This change is brought about by the enzyme, adenase, as a result of either normal degradation or putrefactive processes. It is also found in small amounts in bone marrow.

Caffeine or Theine.—These two names are applied to a well-known purine discovered in 1820 in tea leaves by Ferdinand Runge. Caffeine is found only in vegetable matter, occurring to the extent of 0·8–1·7% in coffee beans, 0·1–0·8% in cocoa beans, 1–2% in Kola nuts, 2–5% in tea leaves, and 2·5–5% in guarana, the roasted fruit of *Paullinia*, which is eaten in South America. It is this purine, along with theobromine and theophylline, which gives the stimulating effects to drinks made from the above sources.

Caffeine has the notable effect of stimulating the central nervous system. In addition it is a cardiac tonic, and, in common with nearly all purines, has a strong diuretic action. In the body it is oxidized to uric acid and excreted as such. There is a tendency among many medical practitioners to warn patients to do without tea and coffee. In certain cases there are undoubtedly very good reasons why caffeine is harmful. For example, in the case of a person suffering with gout, everything must be done to lower purine ingestion, and thus to lessen the load on the already overburdened kidneys. Specially prepared brands of tea or coffee are available from which caffeine has been removed without any alteration of taste. In the case of tea this is done by extracting the leaves with light petroleum to remove the volatile oils which are responsible for the flavour. The caffeine is then removed by extraction with chloroform, after which the original petroleum extract is added to the leaves and the solvent allowed to evaporate, thus restoring to the tea its original flavour. Green coffee beans are treated with live steam and ammonia gas to swell them, the caffeine is then chloroform processed, and the beans subsequently roasted.

Theobromine.—This purine is unfortunately named, for it is devoid of bromine. It was noted first by A. Woskresensky, in 1842, in an extract of cocoa beans, where it occurs to the extent of 1·5–2·4%. This bean is the seed of the plant *Theobroma Cacao* hence the name theobromine. As in the case of caffeine and theophylline, it occurs only in plant matter, being present in the kola nut and in tea leaves, but not in coffee beans. It is a powerful diuretic, and in the body is oxidized to and excreted as uric acid.

Theophylline.—In 1888 A. Kossel discovered very small traces of this purine in tea extract.

Paraxanthine, Heteroxanthine, 1-Methylxanthine and Epiguanine have all at one time or another been isolated from human urine. They are regarded as secondary products, arising from the action of the body on caffeine (*see* p. 780).

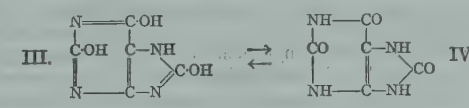
THE CHEMISTRY OF THE PURINES

Purine has the empirical formula, $C_5H_4N_4$, the atoms being joined together according to one or other of the following structural schemes:

In order to endow the many purines with names which may at once be distinctive and descriptive, each atom in the purine ring is given a number, as indicated in formula I.

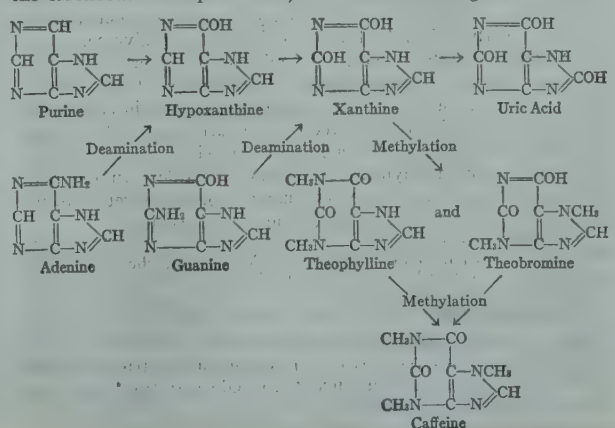
It will be noted that, as the arrows indicate, purine is a mixture of two substances which readily pass from one to another. This mutation is known as tautomerism (*q.v.*). In purine, one of the hydrogen atoms is labile and can pass from the nitrogen atom at 7 to the nitrogen at 9, and vice versa. Any of the four hydrogen atoms in purine may be substituted by any of a large number of groups, the most important being the hydroxyl group (OH), amino- (NH_2), chlorine (Cl), and methyl (CH_3) groups.

A substitution on nitrogen in either the 1 or 3 position is only possible when the hydrogen at either or both of the 2 and 6 positions is substituted by an hydroxyl. For instance, uric acid (2:6:8-trihydroxypurine) is a tautomeric substance, existing



either in the lactim form (III.) or the lactam form (IV.). As a lactim uric acid yields salts with metals, the hydrogen on oxygen being replaceable. The lactam form explains why substitution occurs on the 1 and 3 nitrogen atoms.

The following diagram explains the relationships existing between the purines. Starting with purine, and successively substituting hydroxyl groups for the hydrogen atoms attached to carbon, hypoxanthine, xanthine and uric acid are obtained, these being the mono-, di- and tri-hydroxypurines respectively. Similarly, adenine is a mono-aminopurine and guanine is a mono-aminohypoxanthine.



Uric Acid.—This dibasic acid is a white, finely crystalline substance, insoluble in water and all organic solvents. Alkaline salts of weak acids, such as potassium phosphate, sodium acetate, and particularly lithium carbonate, increase the solubility in water owing to the fact that these salts all form alkaline solutions, and the sodium salt of uric acid is much more soluble than the free acid. (Lithium salts have been used in the treatment of gout on the erroneous assumption that, lithium urate being more soluble

than sodium urate, the uric acid would be eliminated more quickly.) Uric acid, when heated, decomposes into ammonia, carbon dioxide, urea and cyanuric acid. It is unstable and decomposes if left in moderately strong alkali for any length of time. Uric acid is identified by the "murexide" reaction. The suspected substance is evaporated to dryness with nitric acid; if uric acid is present this leaves a yellow spot which when moistened by ammonia turns purple, due to ammonium purpurate formed.

Although uric acid was discovered in 1776, its structural formula was not investigated until 1875, when L. Medicus proposed the formula which has since been established by numerous syntheses.

Guanine is a white amorphous powder, insoluble in water and organic solvents. It is a much weaker acid and stronger base than uric acid. It is, however, such a weak base that ammonia will precipitate it from solution. Owing to the hydroxyl group on carbon, it will dissolve in strong bases, such as sodium hydroxide. The amino-group present in its structure makes it soluble in acids, and thus separable from uric acid. Silver nitrate precipitates guanine in either neutral or alkaline solution, and forms double salts with guanine nitrate. The nitrate is insoluble in strong nitric acid. If treated with nitrous acid, or digested with the enzyme guanase, the amino-group is replaced by hydroxyl giving xanthine.

Adenine crystallizes from water in clusters of leaflets which contain $3H_2O$. When anhydrous it melts at 360–365° F; it is a stronger base than guanine, and hence is not precipitated by ammonia, this difference affording a separation of the two bases. Like guanine, it is precipitated by phosphotungstic or picric acid, the picrate forming beautiful silky yellow needles. Nitrous acid, or the enzyme adenase, decomposes adenine, the resulting replacement of amino- by hydroxyl giving hypoxanthine. Adenine is stable to weak oxidizing agents, but unstable to even mild reducing agents. At 200° F. hydrochloric acid decomposes it completely to carbon dioxide, ammonium formate and glycine acid.

Xanthine, a white crystalline substance forming salts with both strong acids and bases, occurs in nature but is best prepared by the action of nitrous acid upon guano. When heated dry it decomposes into carbon dioxide, ammonia and hydrocyanic acid.

Hypoxanthine occurs as small colourless needles, soluble in both acids and bases. Its hydrochloride crystallizes with one molecule of water. The picrate is very insoluble, and can be used to remove hypoxanthine from solution. This purine is not precipitated by ammonia and is a strong enough acid to decompose carbonates. Hypoxanthine is obtained from adenine by deamination with nitrous acid or adenase.

Theophylline, like theobromine, is a weakly basic substance. Upon oxidation with hydrochloric acid and potassium chlorate it gives dimethylalloxan, in contrast to xanthine, hypoxanthine and uric acid, which give alloxan. When methylated, theophylline and theobromine give caffeine.

Theobromine, an isomeride of theophylline, occurs as colourless needles having a very bitter taste. It is prepared by the methylation of the lead salt of xanthine. Oxidation with hydrochloric acid and potassium chlorate gives methylalloxan and methylurea, whilst boiling with baryta produces methylamine, ammonia, carbon dioxide, formic acid and methylglycine.

Caffeine crystallizes with one molecule of water in beautiful, glistening needles, having a slightly bitter taste. They are sparingly soluble in cold water and alcohol, and soluble in chloroform. It is most conveniently prepared by the extraction of tea. Upon oxidation with hydrochloric acid and potassium chlorate it gives dimethylalloxan, methylurea and carbon dioxide. In the body, caffeine undergoes a number of changes, being excreted as uric acid and four other purine bases mentioned earlier.

PURITANISM. The term "Puritan" was first used during the late 1560s as a label for those Englishmen who urged that the English Church proceed further in the rejection of papal practices and beliefs than it had gone since its formal separation from Rome under Henry VIII. A considerable number of reformers who had supported Henry's attacks on papal authority, which had culminated in the Act of Supremacy in 1534 abolishing the authority of the Roman papacy in England and declaring the king "the only supreme head in earth of the Church of England," had hoped that under his leadership the English Church would be radically reformed. These hopes had been in large measure disappointed. Though the king had been eager for independence from Rome and willing to see such changes in the church as the destruction of monasticism and the modification of the doctrine of purgatory, he had consistently regarded himself as an orthodox Catholic, and he had consistently moulded his policies as head of the church to his plans in foreign affairs. Indeed the Six Articles which Henry had pushed through parliament in 1539, when he had felt it safe to offend German Protestants, set up death penalties for certain Protestant heresies. Thirty years later, under Queen Elizabeth, the more ardent reformers who were still attempting to complete as they saw it the work of purifying the English Church came to be designated, and to designate themselves, as Puritans.

The main body of Puritans had no desire to be separated from the English Church. They simply desired the purification of the established ecclesiastical body. The basis for further purification seemed to them both perfectly clear and absolutely authoritative. It was on an infallible and completely sufficient Bible, rather than on a fallible church or tradition, that they rested their case, and they were horrified by the suggestion of more conservative Protestants that, though the Bible was the ultimate authority for Christians, it provided only general principles of faith and practice and left such matters as the wearing of surplices and the jurisdiction of bishops to determination by the established human authorities.

Confident of the supernatural authority on which they proposed to proceed to a "more thorough reformation," they entertained no plans for tolerating a variety of churches. They were as eager for uniformity as their opponents, and as ready to employ the secular power of the state to enforce it. They shared with Anglicans the belief that the state should have one religion and that the powers of the state should be employed to protect it. Their concern was that this one religion be the "true religion" of the Scriptures. The Puritans of Massachusetts Bay Colony in New England, who in the middle of the 17th century denounced religious toleration and harried Quakers out of the Colony, were neither inconsistent nor drunk with newly acquired power. They were realizing hopes their Puritan ancestors in England had long cherished. A society could be united only if committed to one religion, and heresy was to 16th- and 17th-century Englishmen, Anglican and Puritan alike, tantamount to anarchy or rebellion. For these reasons church and state could not be separated, and defense of the true religion was regarded as one of the proper duties of civil magistrates. Perhaps the most painful of the Puritan's dilemmas, therefore, was that recognizing this responsibility and authority of the state he yet found himself in opposition to the established church. To repudiate that church would be an act of rebellion; to accept it was to defy heaven and to lose his soul. Not until sectarian differences should come to be recognized as politically possible and even legitimate could this dilemma and with it the relation of church and state be resolved. Meanwhile, for the Puritan there remained only one tolerable possibility—the church legitimately established and defended by the state must be purified.

The conflicts which the Puritans on the basis of these principles introduced into the English Church and state during the 16th and 17th centuries revolved with varying emphasis at different periods about three matters: the forms of worship and clerical vestments; the organization of the church; and certain theological doctrines, notably the doctrine of predestination.

With the death of Henry VIII in 1547, the hopes of a more thorough reformation of the English Church, which he had disappointed, were revived. Edward VI was a child of nine when he assumed the throne and the affairs of the kingdom, which included those of the church, were at the outset directed by regents. In response to public sentiment, the heresy laws which under Henry had checked the development of Protestantism were repealed. Reformers like Miles Coverdale thereupon returned to

England from the continent, and in 1549 John Knox, the great Scottish reformer, was released from confinement in the French galleys by the intervention of the English government and welcomed to England. In the same year John Hooper, who had been driven into exile by the enforcement of Henry's Six Articles, returned to England. Shortly thereafter he was offered a bishopric. He professed two difficulties concerning the ordination ceremonies. He could not wear the prescribed clerical vestments and he could not take the oath of office which required the candidate to swear by the saints. The king removed the second of these difficulties by striking the obnoxious words from the ceremony with his own hand, and such good Protestants as Thomas Cranmer and Nicholas Ridley attempted to persuade the candidate that clerical vestments were things "indifferent," the wearing or not wearing of which touched nothing essential in religion. The term "Puritan" was not yet in use, but Hooper's position concerning clerical garb was one to which it was soon to be attached. When Hooper persisted in his objections, he was imprisoned. He finally accepted the advice of continental Protestants, admitted himself in error and was installed in office with the understanding, however, that except for public occasions he might dress as he chose.

At the death of Edward VI in 1553 and the accession of Mary, not merely Puritanism but Protestantism as a whole was threatened. Edwardian acts against Catholicism were abrogated, and in 1554 the acts separating the English Church from Rome were repealed. England was to be returned to Catholic uniformity, and execution for heresy was the accepted instrument of uniformity. The lists included Thomas Cranmer, the first Protestant archbishop of Canterbury, and John Hooper. John Knox fled to the continent where he soon joined a group of English refugees at Frankfurt. Yet even in exile the basic conflict of Anglicanism and Puritanism could not be repressed. Disagreement over the use of the Anglican vestments, ceremonies and prayer book deeply split the Frankfurt group, and Knox was finally driven out. Even in their extremity under Marian persecution, the two wings of English Protestantism, those content with the English establishment and those urging a more thorough reformation, were unable to cooperate.

The anguish of English Protestants was replaced by hope when Elizabeth mounted the throne in 1559. Exiles flocked back to England. But their expectations were soon dashed, for Elizabeth took shrewd advantage of the divisions which Puritanism introduced into the church to consolidate the powers of the monarchy. Under pressure from the crown, parliament passed Acts of Uniformity requiring what Puritans regarded as "popish superstitions." The kneeling posture at the sacrament was enjoined; certain detested clerical vestments were required; and the prayer for deliverance from "the tyranny of the Bishop of Rome" was deleted from the church service. Puritan sentiment was strong enough to come within one vote of passing a petition for reformation at the convocation of the representatives of the established church in 1562, but for both personal and political reasons Elizabeth took measures to repress it. The court of high commission was empowered "to visit, reform, redress, order, correct, and amend errors" in the church, and became a powerful engine against Puritanism.

In 1564 Elizabeth began a campaign for uniformity of clerical vestments. When the queen for political reasons refused to give her signature to a set of articles of uniformity drawn up by Archbishop Matthew Parker, he issued them under the title of *Advertisements* in 1566. The vestiarian controversy which followed served both to divide Protestantism and to discredit the Puritans, whose basic reform purposes were obscured by the fact that the point immediately at issue was a detail of clerical dress. As often happened thereafter, Puritans were made to appear as outrageously overscrupulous concerning trivial matters. Most Puritans offered only passive resistance to the queen's program, since Puritanism neither challenged the authority of the crown nor denied the importance of uniformity in religion, but a few extremists did take the decisive step which Puritan extremists thereafter occasionally followed. They set up independent congregations, ordaining their own church officers and disciplining their own members.

The main body of Puritanism turned rather to an attack on the episcopacy which had enforced the hated "popish" regulations. Leadership was provided by Thomas Cartwright, then Lady Margaret professor at Cambridge, who in 1570 contended that archbishops ought to be abolished and the functions of bishops reduced to those specified in the Scriptures. He was promptly deprived of his post at Cambridge. Puritans, however, enlisted support in parliament for a series of proposals to reform church government. The attempt was terminated abruptly when it seemed on the way to success by an order from the queen that the house consider no bills concerning religion unless they had been previously approved by the clergy. Despite this reversal, parliament took an increasing interest in Puritanism until it brought about the great Puritan triumph of 1640.

Meanwhile, Elizabeth suppressed the efforts of Edmund Grindal, who had been made archbishop of Canterbury in 1576 when Elizabeth, again for political reasons, was temporarily more tolerant of Puritanism, to improve the knowledge and discipline of the clergy by encouraging the practice of "prophesying," the holding of weekly meetings of the clergy for the exposition and discussion of passages of the Bible. Grindal's successor, John Whitgift, returned to the attack on Puritanism by insisting that all the clergy subscribe to a set of articles, one of which, requiring the assertion that the Anglican prayer book "containeth in it nothing contrary to the Word of God," was especially repugnant to Puritans. Whitgift's efforts inspired an attempt to bring about the reform of the church by setting up a presbyterian form of government within the Anglican Church. The leader in this movement was John Field. Efforts to enlist parliament in church reform were, however, blocked by the queen. The Puritan cause was little aided in this period by the appearance in 1588 of the intemperate satire on the bishops by "Martin Marprelate, Gent."

Meanwhile a few extreme Puritans had again been driven to the conclusion that reform from within the established church was impossible, and a few independent congregations had appeared. The most important of these was organized at Norwich by Robert Harrison and Robert Browne in 1581 and shortly thereafter emigrated to Middleburg, where in 1582 Browne published several treatises urging true Christians to withdraw from the Church of England and establish independent churches. Browne later recanted, but his name continued to be attached to the growing party of "Brownists," who under discouragement over the prospect of purifying the established church proposed to separate themselves from it.

Puritan confidence in the rightness of their cause may well have been the source of the optimism with which they greeted each new monarch. They were especially hopeful when after Elizabeth's death James I came to the throne in 1603. A dozen years earlier he had consented to the establishment of Presbyterianism in Scotland. He might be expected to show some favour to Puritanism in England. With high expectations the Puritans presented the new king on his way to London a plea for church reform known as the Millenary Petition because it purported to represent the desires of more than 1,000 clergymen. The king promised a conference at Hampton Court on the matter. It met in Jan. 1604, but when the new king had heard the Puritan case, he rejected it with scorn. "If this be all they have to say, I shall make them conform themselves," he declared, "or I will harry them out of the land, or else do worse." So far as abolishing the episcopacy went, his dictum was "No bishop, no king." James made himself especially obnoxious to the Puritans by publishing in 1618 his *Declaration for Sports on the Lord's Day,* which all ministers were enjoined to read to the congregations on pain of suspension and imprisonment.

One of the chief effects of James's repression of Puritanism was to drive many Puritans into separatism and exile. Among these groups of exiles was the congregation organized at Scrooby which under the leadership of John Robinson moved first to Leyden, Neth., and then in 1620 sent a colony to Plymouth in New England. Other Puritans, reluctant to take the extreme step of separation from the established church, adopted a difficult middle posi-

tion. Chiefly under the guidance of William Ames, fellow of Christ's college, they declared that independent churches on the model of the Scriptures might be set up within the established church. These would merely slough off the evils of the established church while remaining one with it in "essence." It was such a nonseparatist independent group which emigrated to Massachusetts bay in New England during the 1630s, where it had no difficulty in reaching agreement on church government with independents who had settled at Plymouth.

While Puritan aims were thus being frustrated by the crown from Elizabeth's through James's time, the Puritan cause was increasingly successful in parliament. It could be only a matter of time until the conflict between parliament and crown would be irreconcilable, and the Puritan attempt to obey both God and king would have to be abandoned. The climax came in the reign of James's successor, Charles I. Under him severity against nonconformity was increased. Meanwhile, to the conflict over liturgy and church policy was added a difference in theology. Both Anglican conformists and Puritans had hitherto been Calvinists in doctrine. Now the established clergy began to embrace the liberal doctrines of the Dutch theologian Jacobus Arminius while Puritans clung to their Calvinism. In vain parliament supported the Puritan position by passing such acts as the protestation of 1629 that anyone favouring or introducing "popery or Arminianism" should be regarded "as capital enemy to this kingdom and commonwealth." The elevation of William Laud to the archbishopric of Canterbury in 1633 seemed a direct answer to their protest, and during the following seven years ministers who preached the doctrine of predestination in opposition to Arminianism as well as those who attacked "popish ceremonies" were severely dealt with. Laud's zeal drove able and learned men like Thomas Shepard to New England. It finally precipitated the revolt of parliament.

Charles was forced by financial need to summon parliament in 1640. Thoroughly Puritan and thoroughly aroused, parliament brought about the execution of Archbishop Laud and nine years later abandoned the long-standing Puritan policy of passive resistance to bring about the execution of Charles himself. With the overthrow of both the established church and the monarchy, Puritanism strictly speaking may be said to have ended. Puritans split into two parties, Presbyterians and independents, neither of which aimed at the maintenance of the Anglican establishment. The bitter conflict in which they engaged was terminated by the force of Oliver Cromwell's army, which gave victory to the independents. When England had had its fill of civil conflict under the commonwealth and had restored the monarchy in 1660, the old lines again appeared, softened now, however, in the less sanguinary conflicts of high and low church parties within Anglicanism and Presbyterian and Congregational churches outside it. Sectarianism began to be tolerable and uniformity less than essential.

In America the term "Puritan" continued into the 19th century to be involved in bitter religious strife. The nonseparating independents who had settled at Massachusetts bay were typically Puritan in their insistence on the ultimate and complete authority of the Scriptures, on the necessity of uniformity and the evil of toleration, on the responsibility and authority of magistrates in matters of religion and on the truth of the Calvinistic theology. By the middle of the 18th century the conflicts in which American Puritanism engaged centred about the Puritan doctrine of predestination. In this period Jonathan Edwards gave powerful metaphysical formulation to the Calvinist position and rallied its waning forces. But in the generations that followed Edwardian Puritanism succumbed to the criticism of men like William Ellery Channing, and the term "Puritan" came finally to be applied to over-precise moralists or to reformers intent on such matters as the abolition of alcohol or tobacco. Historically these latter-day Puritans had little relation to the Puritanism of Elizabeth's time in old or in New England, who would have been as little interested in prohibition, for example, as modern so-called Puritans are in vestiarian reform.

Knapper, *Tudor Puritanism* (1939). (C. H. F.)

PURLIEU, a word used of the outlying parts of a place or district, sometimes in a derogatory sense. It was a term of the old English forest law and meant, as defined by John Manwood (*Treatise of the Forest Laws*), "a certain territory of ground adjoining unto the forest . . . which . . . was once forest-land and afterwards disafforested by the perambulations made for the severing of the new forests from the old." The owner of free lands in the purlieu to the yearly value of 40 shillings was known as a "purlieuman" or "purleyman."

PURLIN, in architecture, the longitudinal timbers of a roof, carried by the principal rafters or trusses and the end walls, and supporting the common rafters.

PURNEA, a town and district of former British India, in the Bhagalpur division of Bihar. The town is on the little river Saura, with a railway station. Pop. (1941) 19,036.

The DISTRICT OF PURNEA had an area of 4,998 sq.mi. and a population (1941) of 2,390,105, extending from the Ganges northward to the frontier of Nepal. It is a level tract of country, traversed by several rivers flowing from the Himalaya, the greatest of which is the Kosi, which has been known to move 20 mi. in 25 years, leaving behind it a trail of sterile sand. The principal crops are rice, pulses and oilseeds. Although the cultivation of indigo declined, that of jute greatly increased.

Branches of Eastern Bengal State railway join the Bengal and North-Western railway at Katihar (pop. 23,231). Kishanganj (pop. 10,424) is the centre of the jute trade and is a branch terminus of the Darjeeling-Himalayan railway.

PURNELL, THOMAS (1834–1889), English author, was born in Tenby, Pembrokeshire, in 1834. He studied at Trinity college, Dublin, and was assistant secretary and librarian of the Archaeological Institute of Great Britain and Ireland, 1862–66.

In 1871 he published *Dramatists of the Present Day* (London), a reprint of his series of articles which first appeared in 1870–71 in the *Athenaeum* under the pseudonym "Q." He also edited Charles Lamb's *Correspondence and Works* (1871). Other works include *Literature and Its Professors* (London, 1867); *To London and Elsewhere* (London, 1881); and *Dust and Diamonds: Essays* (London, 1888).

PURNELL, WILLIAM HENRY (1826–1902), U.S. lawyer and educator, was born on Feb. 3, 1826, in a rural area of Worcester county, Md. In 1846 he graduated from Delaware college, which later became the University of Delaware, and in 1848 he was admitted to the bar. Purnell held various state offices in Maryland, 1850–59. He was appointed deputy postmaster of Baltimore in 1861 and was chairman of the Union party state central committee, 1864–66.

After the senate in 1867 refused to confirm his appointment to the post of assessor of internal revenue at Baltimore, he practised law there. Purnell was president of Delaware college, 1870–85, and an instructor there from 1897 until his death on March 30, 1902.

PURPLE, SAMUEL SMITH (1822–1920), U.S. physician and editor, was born in Lebanon, N.Y. on June 24, 1822. After his father died in 1839, Purple began at the age of 17 to support his family by continuing his father's small shoemaking and tanning business.

He studied at Geneva Medical college and in 1844 graduated from the New York university medical college. In 1846 he became physician at the New York city dispensary, and in 1849, the year of the New York cholera epidemic, he was the board of health ward physician. Purple was editor of the *New York Journal of Medicine*, 1848–58. One of the founders of the New York Academy of Medicine, he was president of the academy, 1875–79.

Purple became a leading book collector, and from 1874 to 1886 he edited the *New York Genealogical and Biographical Record.*

See *New York Genealogical and Biographical Record* (Jan. 1901).

PURPLE, a shade varying between crimson and violet. Formerly it was used of the deep crimson colour called in Latin *purpura,* from the name of the shellfish (*Purpura*) which yielded the famous Tyrian dye. Tyrian purple during many ages was the most celebrated of all dyed colours, and possibly the first to be permanently fixed on wool or linen. Being extremely costly, robes of this colour were worn as a mark of imperial or royal rank, whence the phrase "born in the purple." In the Roman Catholic church "promotion to the purple" is promotion to the rank of cardinal.

The ancients derived their purple from the mollusc, *Purpura haemastoma,* known to Pliny as "Buccinum," and *Murex brandaris,* termed by Pliny "Purpura," the shells of which have been found adjacent to ancient dyeworks at Athens and Pompeii. The colour-producing secretion is contained in a small cyst adjacent to the head of the animal, and this pus-like matter when spread on textile material in presence of sunlight develops a purple-red colour. According to Pliny these receptacles after being laid in salt were boiled with water for several days, the liquor being tested from time to time as to its dyeing properties. Before dyeing the wool could be grounded with a second colouring matter, for which purpose alkanet root (*Anchusa tinctoria*) and "orchil" were employed. Friedländer has shown that the dye developed from the molluscs is 6:6′-dibromoindigotin. (A. G. P.)

PURPURA includes a group of loosely related diseases that are characterized by spontaneous haemorrhages into the skin and from the mucous membranes. The cutaneous haemorrhages are usually small and are referred to as petechiae or ecchymoses.

(1) Symptomatic purpuras are those that are definitely secondary to some other disease. They may occur in destructive diseases of the bone marrow such as leukemia (leucaemia), aplastic anaemia and metastatic carcinoma; in fulminant infections as haemorrhagic smallpox, haemorrhagic measles and meningococcic bacteriaemia; following the use of certain drugs as arsenical preparations, thiosulphate, sulfonamides and sedormid; and in vitamin C deficiency (scurvy). The blood platelets are usually reduced in number during the attacks, and there is often evidence of destruction of the megakaryocytes in the bone marrow from which the platelets are formed. Treatment is directed toward the underlying disease.

(2) Primary thrombopenic purpura includes all forms of unknown aetiology. During attacks the blood platelets are reduced in number and the bleeding time is prolonged. The coagulation time of the blood is unaffected. The disease varies from a mild form with little disturbance other than cutaneous haemorrhages to fulminant cases in which the patient dies because of massive bleeding from the mucous membranes or from a haemorrhage in the brain. Bleeding from mucous membranes may be more conspicuous than the cutaneous haemorrhages. The most frequent clinical form is a chronic recurrent purpura in which the patient is free from symptoms between attacks. Orthostatic purpura refers to the form in which the cutaneous haemorrhages develop in the lower extremities as a result of increased venous pressure. In addition to haemorrhages the outstanding features are the prolonged bleeding time and the reduced number of blood platelets. There is an associated disease of the blood capillaries, since they do not retract readily after they are cut and when the skin is pricked with a needle the bleeding continues longer than usual.

In cases where the loss of blood becomes serious it is usually advisable to remove the spleen since this will stop the bleeding in most instances. The beneficial effect of splenectomy is not understood since the spleen shows no recognizable disease. Primary thrombopenic purpura is believed to be a form of hypersplenism. Splenectomy is not indicated in juvenile purpuras since these usually recover spontaneously, and it is of no value in symptomatic purpuras. (E. T. Be.)

PURRAH, Purroh or Poro, a secret society of Sierra Leone, West Africa. Only males are admitted to its ranks while the Bundu is strictly reserved to women.

The Purrah had its special ritual and language, markings and symbols and exercised authority by the imposition of tabus which were enforced by various methods. In 1897 the British local government was compelled to pass a special ordinance absolutely forbidding the imposition of the tabu on all indigenous products.

See T. J. Alldridge, *The Sherbro and its Hinterland* (1901); N. W. Thomas, *Anthropological Report on Sierra Leone,* Part I. (*Law and Custom of the Timne and other tribes*).

PURSH, FREDERICK (1774–1820), American botanist, was born at Tobolsk, Siberia, in 1774. He received his education in Dresden, Germany. In 1799 he went to the United States where he devoted 12 years to botanical exploration and the scientific study of North American plants. In 1811 he visited England and in 1814 he brought out in London his important *Flora Americae Septentrionalis.* He then returned to the U.S. and resumed his botanical investigations. On one of his solitary tours afoot he discovered the hart's-tongue (*q.v.*), one of the rarest of the ferns in North America. He died at Montreal, Can., June 11, 1820.

PURSLANE, the common name for a small fleshy annual with prostrate stems, entire leaves and small yellow flowers, known botanically as *Portulaca oleracea* (family Portulacaceae). It is a native of India, which was introduced into Europe as a salad plant, and in some countries has spread so as to become a noxious weed; it is found in England but is rare. In certain parts of the United States the evil qualities of "pussly" have become proverbial. The persistence of purslane plants is due to their ability to retain moisture and thus blossom and ripen seeds long after they have been removed from the soil. The capsules opening by a lid produce many small seeds of great longevity. Besides the common purslane, some 10 other species occur in North America, chiefly in the southern United States. Some of the species of the same genus, such as *P. grandiflora* and its varieties, are grown in gardens on rockwork.

PURSUIVANT, a member of the third and lowest rank of heraldic officers, formerly an attendant on the heralds.

PURVEYANCE was a prerogative of purchasing goods for the royal household, enjoyed by all English kings up to Charles II. Certain officers attached to the king's court were charged with the duties of buying and arranging for the cartage of goods where necessary, the ancient prerogative of the King entitling him to demand carriage services from his subjects. The possibilities of abuse were obvious. Magna Carta (*q.v.*) ordered that goods should be paid for at once, and that horses and carts should not be taken for carriage duty, nor timber taken for castles without the consent of the owner. These stringent regulations were considerably modified to the King's advantage in later issues of the charter.

Many early statutes were passed against purveyance. People particularly resented the exercise of this right by royal officials and ministers for their own benefit. Statutes therefore limited its use to the immediate households of the king and queen. The name purveyor was so much hated that it was provided by statute that it should be changed to *achatour* (buyer). But statutes had little effect. In Elizabeth's reign complaints against purveyance were particularly bitter. In her early years the queen seems to have made use of her rights of purveyance to victual her navy. Later an arrangement was made by which some, if not all, counties agreed to furnish definite provisions at a fixed rate in order to get rid of the uncertainty which made the burden so much heavier. These compositions were arranged between the officers of the Board of Green Cloth and the Justices of Peace for each county at fixed prices. These fixed prices were very much lower than the market value of the goods and the difference was met by an assessment on the county. Cattle supplied in this way were kept in certain royal pastures. The parliaments of James I. determined to get rid of the abuses of purveyance, and Sir Francis Bacon made a famous speech against the purveyors in the first parliament of the reign. It was held that only the abolition of the right would put an end to its abuse. The purveyors made a practice of demanding far more goods than were necessary and sold the surplus for their own advantage. They ordered goods to be taken to remote places that people might buy from them exemption from coming with their portions. There were innumerable ways in which purveyors could make dishonest profit. Despite complaints, the right of purveyance went on until it fell into disuse during the Commonwealth. Its abolition was part of the Restora-

tion Settlement, though till the end of the century it was sometimes partially revived during royal progresses. (D. M. S.)

PURVĪTIS, VILHELMS KĀRLIS (1872–1945), Latvian landscape painter, was born in Zaube rural district, Latvia, on March 3, 1872, and attended a secondary school in Latgale province. He later abandoned his father's milling business for painting, graduating from St. Petersburg academy in 1897; awarded a Rome prize, he travelled widely in western Europe. After teaching at Tallinn cathedral school (1906–09) he directed the Riga state art school until it was closed in 1916; from 1913, when he was elected academician of St. Petersburg academy, he was also director of the state museum and professor at Riga university. He organized the independent Latvian Academy of Arts in 1919 and was its rector and professor until 1934. In 1934–36 he edited a history of art. Purvītis introduced Impressionism into northeastern Europe, developing from it the Baltic landscape style; later, his methodical compositions became more colourful and expressionistic. Many of his pictures were destroyed by military action at Jelgava, Latvia, in July 1944; others, evacuated to Bavaria, disappeared. A refugee, Purvītis died at Nauheim, Hesse, Ger., on Jan. 18, 1945.

PUSA, a village of British India, in Darbhanga district, Bihar province, near the right bank of the Burh Gandak river; and 6 mi. from the Pusa Road station on the Bengal and North-Western railway. The Government acquired an estate here in 1796, long used as a stud depot and afterwards as a tobacco farm. The estate, which covers 1,280 ac. was made over in 1904 to the Imperial Agricultural Department (of the Government of India), of which it is the headquarters. The Research Institute here comprises, in addition to a farm, an agricultural college, at which officers are trained for the higher posts in the Agricultural Department, and a research laboratory bearing the name of Mr. Phipps, an American gentleman, who contributed £30,000 towards its cost. The institute, which owed its inception to Lord Curzon, has, within the comparatively short period of its existence, done magnificent service to Indian agriculture by producing improved varieties of crops. In particular, it has achieved remarkable success by evolving strains of wheat which give a high yield, have powers of resistance to rust, are able to mature with less water than the generality of Indian wheats, and give good results under diverse conditions of soil and climate. The Pusa varieties are now grown on over 1½ million acres of the United Provinces, the Punjab and the North-Western Frontier province. The institute has also produced a heavy-yielding variety of bearded wheat suitable for areas where the crop is liable to damage by birds. The institute has introduced berseem, or Egyptian clover. It has been proved that a small irrigated area of poor land, in which berseem is followed by early maize, can provide a large herd with all the bulky green food it requires—a discovery of immense importance in a country depending so largely on cattle, where the pasture lands are for a large part of the year parched and bare. Further, valuable results have been obtained by selective breeding of cattle, *e.g.*, by doubling the milk yield of a pure herd in ten years. In order to improve both the quality and quantity of sugar production, a Sugar Bureau has been established, which gives advice to cultivators, manufacturers, etc. The institute studies soil improvement and the use of phosphates found in India.

PUSEY, EDWARD BOUVERIE (1800–1882), English divine, was born at Pusey near Oxford on Aug. 22, 1800, the son of Philip Bouverie, who took the name of Pusey on succeeding to the manor of that name. Edward Pusey was educated at Eton and at Christ Church, Oxford, and became a fellow of Oriel in 1824. He thus became a member of a society which included J. H. Newman and John Keble. Between 1825 and 1827 he studied Oriental languages and German theology at Göttingen. In 1828 the duke of Wellington appointed him to the regius professorship of Hebrew with the canonry of Christ Church.

By the end of 1833 he showed a disposition to make common cause with those who had already begun to issue the *Tracts for the Times.* "He was not, however, fully associated in the movement till 1835 and 1836, when he published his tract on baptism and started the Library of the Fathers" (Newman's *Apologia,* p. 136). He became a close student of the fathers and of that school of Anglican divines who had continued, or revived, in the 17th century the main traditions of pre-Reformation teaching. A sermon which he preached before the university in 1843, *The Holy Eucharist, a Comfort to the Penitent,* so startled the authorities that he was suspended for two years from preaching. The effect of his suspension was the sale of 18,000 copies of the condemned sermon and Pusey at once became an influence in the Anglican Church.

The movement, in the actual origination of which he had had no share, came to bear his name: it was popularly known as Puseyism (sometimes as Newmania) and its adherents as Puseyites. His activity, both public and private, as leader of the movement was enormous. He was not only on the stage but also behind the scenes of every important controversy, whether theological or academical. In the Gorham controversy of 1850, in the question of Oxford reform in 1854, in the prosecution of some of the writers of *Essays and Reviews,* especially of Benjamin Jowett, in 1863, in the question as to the reform of the marriage laws from 1849 to the end of his life, in the Farrar controversy as to the meaning of everlasting punishment in 1877, he was always busy with articles, letters, treatises and sermons. Some of his sermons before the university marked distinct stages in the history of the High Church party which he led.

The revival of confession in the Church of England practically dates from his two sermons on *The Entire Absolution of the Penitent,* in 1846. The sermon on *The Presence of Christ in the Holy Eucharist,* in 1853, first formulated the doctrine round which almost all the subsequent theology of his followers revolved, and which revolutionized the practices of Anglican worship. Of his larger works the most important are: his two books on the Eucharist—*The Doctrine of the Real Presence* (1855) and *The Real Presence . . . the Doctrine of the English Church* (1857); *Daniel the Prophet* in which he endeavours to maintain the traditional date of that book; *The Minor Prophets, with Commentary,* his chief contribution to the study of which he was the professor; and the *Eirenicon,* in which he endeavoured to find a basis of union between the Church of England and the Church of Rome.

In private life Pusey's habits were simple almost to austerity. He had few personal friends, and rarely mingled in general society; though bitter to opponents, he was gentle to those who knew him, and his munificent charities gave him a warm place in the hearts of many to whom he was personally unknown. The deaths of his wife (1839) and of his only son (1880) saddened his life. He died on Sept. 16, 1882, and was buried at Oxford in the cathedral of which he had been for fifty-four years a canon. In his memory his friends purchased his library, and endowed for it a house in Oxford, known as Pusey House.

See B. W. Savile, *Dr. Pusey, an Historic Sketch, with Some Account of the Oxford Movement* (1883); the *Life* by Canon Liddon, completed by J. C. Johnston and R. J. Wilson (5 vols., 1893–99); Newman's *Apologia,* and other literature of the Oxford Movement.

Pusey's elder brother, PHILIP PUSEY (1799–1855), was a member of parliament and a friend and follower of Sir Robert Peel. He was one of the founders of the Royal Agricultural Society, and was chairman of the implement department of the great exhibition of 1851. He was a fellow of the Royal Society, a writer on varied topics for the reviews and the author of the hymn "Lord of our Life and God of our Salvation."

PUSHBALL, a game played by two sides on a field usually 140yds. long and 50yds. wide, with a ball 6ft. in diameter and 50lb. in weight. The sides usually number 11 each, there being five forwards, two left wings, two right wings and two goalkeepers. The goal consists of two upright posts 18ft. high and 20ft. apart with a crossbar 7ft. from the ground. The game lasts for two periods with an intermission. Pushing the ball under the bar counts five points; lifting or throwing it over the bar counts eight. A touch-down behind the goal for safety counts two to the attacking side. The game was invented by M. G. Crane of Newton, Massachusetts, in 1894, and was taken up at Harvard University the next year, but has never attained any considerable vogue. In Great Britain the first regular game was played at the Crystal Palace in 1902 by teams of eight. The English rules are somewhat

different from those obtaining in the United States. Pushball was one of the games frequently played by teams of military men at the training camps during the World War. It is usually considered one of the feature events at American circuses when played by teams of Indians and cowboys on horseback. It is also played by mounted organizations of the U.S. army at various military posts. Pushball on horseback was introduced in 1902 at Durland's riding academy in New York, and has been played in England at the Military Tournament.

PUSHKIN, ALEXANDER (1799–1837), Russian poet, was born at Moscow on June 6, 1799. He belonged to an ancient family of boyars; his maternal great-grandfather was an Abyssinian general in the Russian service, ennobled by Peter the Great. In 1811 the future poet entered the newly founded lyceum of Tsarkoe Selo, situated near St. Petersburg. On quitting the lyceum in 1817 he was attached to the ministry of foreign affairs, and in this year he began to write his *Ruslan and Ly'udmila,* a romantic epic in six cantos, which was completed in 1820. Meanwhile Pushkin mixed in all the gayest society of the capital, and it seemed as if he would turn out a mere man of fashion instead of a poet. But a very daring *Ode to Liberty* written by him and circulated in manuscript in St. Petersburg came to the notice of the governor, and the young author was exiled to the south of Russia where he held official positions at Ekaterinoslav and at Kishinev.

In company with General Rayevsky he visited the baths of the Caucasus for the re-establishment of his health in 1820. The Rayevskys introduced him to the poetry of Lord Byron, and the magnificent scenery of the Caucasus kindled his own poetic genius. The first fruit of the Caucasian visit was *The Captive of the Caucasus* (1822), narrating the story of the love of a Circassian girl for a Russian officer. This was followed by the *Fountain of Bakhchisarai* (1827) which tells of the detention of a young Polish captive in the palace of the khans of the Crimea. About the same time he composed the lines on Ovid, whose place of banishment, Tomi, was not far distant, and the *Ode to Napoleon.* The next long poem was the *Gipsies* (Tsygany) (1827). During his stay in southern Russia he mixed with the secret societies then rife throughout the country. In 1823 he was allowed to leave Kishinev, where the life was hateful to him, and was transferred to Odessa where he was once more on real Russian soil, and on the coast of the sea which delighted him. But he came into conflict with his official superior, and was dismissed from the service, because of an intercepted letter in which he spoke favourably of atheism. He was ordered to reside at Mikhailovskoe, near Pskov, where he soon involved himself in trouble on all sides. In his retirement he studied old Russian popular poetry. Recollections of Byron and André Chenier gave the inspiration to some fine lines consecrated to the latter, in which Pushkin appeared more conservative than was his wont. In 1825 he wrote his tragedy *Boris Godunov,* not published till 1831, a bold effort to imitate the style of Shakespeare, thus breaking with the French traditions.

In 1825 the conspiracy of the Dekabrists broke out. Many of the conspirators were personal friends of Pushkin, especially Küchelbecker and Pustchin. The poet himself was to a certain extent compromised, but he succeeded in getting to his house at Mikhailovskoe and burning all the papers which might have been prejudicial to him. The emperor, to whom he was presented at Moscow soon after his coronation, summoned him to Moscow and assured him of pardon and "protection." The story goes that Nicholas said to Count Bludov on the same evening, "I have just been conversing with the most intelligent man in Russia." In 1829 appeared *Poltava,* a spirited narrative poem, in which the expedition of Charles XII. against Peter and the treachery of the hetman Mazeppa were described. In 1829 Pushkin again visited the Caucasus on this occasion accompanying the expedition of General Paskevich, which is described in *A Voyage to Arzrum* (pr. 1836). The lyrics are delightful. In 1831 Pushkin married Natalia Goncharov, and in the following year was again attached to the ministry of foreign affairs, with a salary of 5,000 roubles. He now began his *History of the Revolt of Pugachev of 1773* (pr. 1834) an admirable piece of historical writing. While engaged upon this he wrote *The Captain's Daughter* (1836), one of the best of his prose works. In 1832 was completed the poem *Evgeni Onegin* (1825–33), again influenced by Byron.

In 1837 the poet, who had been long growing in literary reputation, fell mortally wounded in a duel (Feb. 8) with Baron George Heckeren d'Anthès, the adopted son of the Dutch minister who had married a sister of the poet's wife. Pushkin died on Feb. 10. D'Anthès was tried by court-martial and expelled from the country. In 1880 a statue of the poet was erected at the Tver Barrier at Moscow. He left four children; his widow married an officer named Lanskoi; she died in 1863.

Pushkin's poetical tales are full of drama. *Boris Godunov* and *Evgeni Onegin* are the basis of operas by Mussorgsky and Tschaikowsky respectively. Pushkin's lyrical pieces are the finest in the language. Interspersed among his minor works will be found many epigrams. He was one of the earliest Russian novelists. Indeed most of his work after 1831 was done in prose. In 1831 he published a small volume of tales under the pen name of Ivan Belkin. These all show great narrative powers. The one long novel finished is *The Captain's Daughter,* a tale of the times of Catherine II., which exercised a great influence on later Russian novelists. The most famous of all his short stories is *The Queen of Spades* (1834). In the *History of the Manor of Goryukhino* (1857), Pushkin parodied Polevoy's *History of the Russian People,* and presented an amusing picture of the fictitious author of his own Tales, Ivan Petrovich Belkin.

See Prince D. S. Mirsky, *Pushkin* (1926), which contains a bibliography; and the bibliography in the editions of Gennadi (7 vols., St. Petersburg, 1861), and Annenkov (6 vols. St. Petersburg, 1855).

PUSHTU, PAKHSTO, PAKKHTO (Pashto), the language of the Afghans, belongs to the Eastern Iranian group, the oldest form of which is probably found in the Zend. Numerous terms are traceable to the Avesta. (*See* Paul Horn's *Grundriss der Neupersischen Etymologie*). The remainder of its vocabulary comes from Arabic, Persian and from the Indian Prakrits. Among the last, Sindhi takes first place. It has thus considerable claims to antiquity.

About 10% of the Afghans are able to read and write, and education is making rapid progress.

Structure.—There are nine declensions. The accusative is the same as the nominative. The agent and oblique forms are identical. The genitive, dative and locative are formed by adding suffixes to the oblique form. Most adjectives form the feminine by adding *a.* Pronominal suffixes are used as well as definite, personal, demonstrative and reflexive pronouns. The regular verb has two main tenses, the imperfect and the present. There are 37 classes of verbs, 13 intransitive and 24 transitive.

Gilbertson, *The Pakkhto Language* (Hertford, 1929). Dictionary: G. W. Gilbertson, *English-Pakkhto Colloquial Dictionary* (Hertford, 1929).

PUT AND CALL: *see* Options.

PUTEOLI, an ancient town of Campania (mod. *Pozzuoli, q.v.*), Italy, on the northern shore of the Bay of Puteoli, a portion of the Bay of Naples, from which it is 6 m. W. The city was probably founded under the name of Dicaearchia by a colony of Samians from Cumae about 520 B.C., before which Misenum was the original port. In 215 the Romans introduced a garrison of 6,000 men and Hannibal besieged it in vain in 214. In 194 a Roman colony of 300 men was established. Puteoli belonged to the tribus Palatina, thus breaking the rule (the only other exception is Turris Libisonis [*q.v.*] which belonged to the Colluia) that *municipia* and *coloniae* were not enrolled in the four urban tribes. The *lex parieti faciundo,* 105 B.C., relating to building works in front of the temple of Serapis, shows that Puteoli had considerable administrative independence. Sulla retired to Puteoli after his resignation of the dictatorship in 79. Cicero had a house in Puteoli itself, and a villa on the edge of the Lucrine lake (*q.v.*), and many other prominent men of the republic possessed country houses near by. (*See* Baiae; Avernus; Lucrinus Lacus; and Misenum.) In A.D. 61 St. Paul landed here, and spent seven days before leaving for Rome (Acts xxviii. 13). Vespasian gave the town part of the territory of Capua, and installed more colonists

—whence it took the title Colonia Flavia.

The remains of Hadrian, who died at the neighbouring town of Baiae, were at first deposited at Puteoli, and Antoninus Pius erected a temple to his memory on the site of Cicero's villa. It was mainly, however, as a great commercial port that Puteoli was famous in ancient times. It exported iron from Elba, mosaics, pottery, perfumes, pozzolana earth (taking its name from the place), glass cups engraved with views of Puteoli, mineral dyes, etc., but its imports were considerably greater. During the Punic Wars it was a naval port, but in the latter part of the 2nd century B.C. it became the greatest commercial harbour of Italy and we find Lucilius about 125 B.C. placing it next in importance to Delos, then the greatest harbour of the ancient world.

The corn supply of Rome came partly through Puteoli, partly through Ostia. Seneca (*Epist.* 77) describes the joy of the inhabitants in the spring when the fleet of corn vessels from Alexandria was seen approaching, and Statius tells us that the crew of the ship which arrived first made libations to Minerva when passing the promontory which bore her name (the Punta Campanella at Sorrento).

Claudius established here, as at Ostia, a cohort of *vigiles* as a fire-brigade. Brundisium was similarly protected. There was also a station of the imperial post, sailors of the imperial fleet at Misenum being apparently employed as couriers. The artificial mole was probably of earlier date than the reign of Augustus; and by that time at any rate there were docks large enough to contain the vessels employed in bringing the obelisks from Egypt. Alaric (410), Genseric (455) and Totila (545) devastated Puteoli.

The original town of Puteoli stood on the narrow hill of the Castello. The streets of the old town preserve the ancient alinement. There are also traces of the division of lands near the town into squares by parallel paths (*decumani* and *cardines*) at regular intervals of 1,111⅓ Roman feet, postulating as the basis of the division a square with a side of 10,000 Roman feet, divided into 81 smaller squares. The market hall (*macellum*), generally known as the temple of Serapis, from a statue of that deity found there, was excavated in 1750. In the centre of the ancient city was a round colonnade with sixteen columns of Numidian marble (*giallo antico*) now in the theatre of the palace at Caserta. In the amphitheatre there were exceedingly interesting arrangements for flooding the arena, but these can only have been in use before the construction of the greater part of the subterranean portion with its cages, etc. The whole amphitheatre is 489×381 ft.; the arena 245×138 ft. Inscriptions record that it was built by the *Colonia Flavia, i.e.*, not before Vespasian. In the older amphitheatre (426×312 feet), which was found in excavations for the new railway to Naples, Nero fought in games given in honour of Tiridates, king of Armenia. Remains of thermae also exist in various places. The cathedral of S. Proculus (containing the tomb of the musician Pergolesi, d. 1736) is built into a temple of Augustus, 6 columns of which, with their Corinthian capitals, still exist. Other ruins—of a circus, of tombs, villas, etc., exist.

Puteoli was supplied with water by two aqueducts, both subterranean, one of which, bringing water from springs in the immediate neighbourhood, is still in constant use. Puteoli was reached direct by a road from Capua traversing the hills to the north by a cutting (the Montagna Spaccata), which went on to Neapolis, and by the Via Domitiana from Rome and Cumae. There was also a short cut from Puteoli to Neapolis by the tunnel of Pausilipon, made under Augustus. In 305, S. Januaris (S. Gennaro, the patron saint of Naples), bishop of Beneventum, S. Proculus, patron of Puteoli, and others, were martyrs at Puteoli.

See the study of C. Dubois, *Pouzzoles antique* (Paris, 1907) (Bibliothèque des écoles françaises d'Athènes et de Rome, fasc. 98). (T. A.)

PUTNAM, GEORGE HAVEN (1844–1930), dean of American publishers, at eighty-five (1929) the active head of one of the oldest publishing houses in the country, the house that gave to American literature such names as Washington Irving and Fenimore Cooper; with sixty-five years of publishing experience behind him, he had time to win honors as a soldier, a writer, and a man of public affairs.

This sterling American citizen, whose forefathers fought for George Washington, and who himself languished in Libby prison, upholding the Union cause, was born in England on April 2, 1844. His father, George Palmer Putnam, had founded the American publishing concern in 1837, and after that date had found it important for his publishing business to make annual trips to England. In 1841, he brought into organization the London publishing house, being the first American publisher to invade England. He was a resident of England for seven years, and it was in this way that his son came to be born in London.

It was not until 1848, that young George Haven Putnam was brought to America. Among his early memories are such outstanding figures as Washington Irving, Charles Dickens, Thackeray, Louis XVII. ("Eleazar Williams"), and Lincoln.

The major's father was a member of the Committee that invited Lincoln to New York in 1860, and the younger Putnam sat on the platform during the delivery of the Cooper Union address. After the address, he was introduced by Bryant to Lincoln.

His boyhood education was completed at Columbia grammar school, followed by studies abroad at the Sorbonne and the University of Göttingen, studies which were cut short by the beginning of the Civil War. Mr. Putnam hastened home from Europe in 1862 to enlist in the Union Army. He was taken prisoner at Cedar Creek, and sent to Libby Prison and later to Danville.

Major Putnam's outstanding contribution to publishing history was his championship of international copyright, which resulted, in 1891, in the present copyright relations between the United States and Europe. He died in New York city on Feb. 27, 1930.

PUTNAM, HERBERT (1861–), American librarian, was born in New York city on Sept. 20, 1861. He graduated from Harvard college in 1883 and thereafter studied law at Columbia university, being admitted to the bar in 1886. His calling, however, proved to be that of librarian. He was librarian of the Minneapolis Athenaeum in 1884–87, of the Minneapolis Public library in 1887–91 and, after a few years spent in the practice of law, of the Boston Public library in 1895–99. Thence he was called in 1899 to the librarianship of the Library of Congress, in Washington. He was president of the American Library association in 1898 and 1904 and wrote on library science.

PUTNAM, ISRAEL (1718–1790), American soldier, was born in Salem Village (now Danvers), Mass. on Jan. 7, 1718, and in 1740 removed to a farm in the vicinity of Pomfret, Conn. He was active in the French and Indian War, rising to the rank of major in 1758. News of the fighting at Lexington and Concord reached him while he was ploughing on his farm; he instantly left the plough in the furrow and hastened to Cambridge; and he was later made second brigadier of the Connecticut forces. He was with the force, commanded by Col. William Prescott, which on the night of June 16, 1775, fortified Breed's Hill, and on the next day he took a conspicuous part in resisting the British attack (*see* BUNKER HILL). After the evacuation of Boston he was in command of New York city till Washington's arrival (April 13, 1776), and then was put in general charge of the city's fortifications. Immediately before the battle of Long Island he succeeded Gen. John Sullivan in command of the troops on Brooklyn Heights, and in the battle of Long Island (of Aug. 27) he was in immediate command of the American side. In the retreat from New York city he took part in the battle of Harlem Heights (Sept. 16). In May, 1777, he took command of the Hudson highlands at Peekskill, which with Forts Montgomery and Clinton he abandoned in October, being out-manoeuvred by the British. After a few months' recruiting service in Connecticut he returned to the main army at White Plains. In the winter of 1778–79 he commanded the troops quartered near Redding, Conn. In May, 1779, he took command of the right wing on the west side of the Hudson. An attack of paralysis in Dec. 1779 terminated his active service in the war. He spent his last years on his farm in Brooklyn, Conn., where he died May 29, 1790. A bronze equestrian statue by Karl Gerhardt, over a sarcophagus, was erected at Brooklyn, Conn., by the State in 1888, and there is another statue (1874) in Bushnell park, Hartford, by J. Q. A. Ward.

Putnam was a brave, intrepid and very industrious soldier rather than a great general. His bluff heartiness has made him

one of the popular heroes in American history.

See W. F. Livingston, *Israel Putnam, Pioneer, Ranger and Major-General* (1901) in the "American Men of Energy" series; I. N. Tarbox, *Life of Israel Putnam* (Boston, 1876); and *Essay on the Life of the Honorable Major-General Israel Putnam* (Hartford, 1788; enlarged ed., Boston, 1818), by David Humphreys, for a time Putnam's aide-de-camp.

PUTNAM, RUFUS (1738–1824), American soldier and pioneer, was born in Sutton, Mass., on April 9, 1738 (O.S.). He served in the French and Indian War in 1757–60; was a millwright in New Braintree in 1761–68, during which time he studied surveying; and from 1769 until the American Revolution was a farmer and surveyor. He became lieutenant colonel in one of the first regiments raised after the battle of Lexington, and served before Boston. In 1777 he served in the Northern army under Gen. Horatio Gates, commanding two regiments in the second battle of Saratoga. In 1778 he laid out fortifications, including Ft. Putnam, at West Point, and in 1779 he served under Gen. Anthony Wayne after the capture of Stony Point. After the war he returned to Rutland, Mass., where he had bought a confiscated farm in 1780. In March, 1786, he founded, with other officers of the American Revolution, the Ohio Company of Associates for the purchase and settlement of Western lands. In Nov. 1787, he was appointed by the company superintendent of its proposed settlement on the Ohio, and in 1788 he led the small party which founded Marietta, Ohio. He was a brigadier-general in the army and a commissioner to treat with the Indians in 1792–93; was surveyor general of the United States in 1796–1803; and in 1802 was a member of the Ohio State Constitutional convention. He died, in Marietta, May 4, 1824. He has been called "the father of Ohio," and greatly contributed to its development.

Campbell, *Biographical Sketches* (1838); Sidney Crawford, "Rufus Putnam, and his Pioneer Life in the North-West," vol. xii, new series, pp. 431–454, *Proceedings of the American Antiquarian Society* (1899), and Rowena Buell (ed.), *The Memoirs of Rufus Putnam* (1903), in which his autobiography, journal and other papers, in the library of Marietta college, are reprinted. His *Journal, 1757–1760,* dealing with his experiences in the French and Indian War, was edited with notes by E. C. Dawes (1886).

PUTNAM, a city of northeastern Connecticut, U.S., on the Quinebaug river, at the mouth of the Little river; the county seat of Windham county. It is served by the New York, New Haven and Hartford railroad. Pop. (1950) 8,165; (1940) 7,775. It manufactures cotton, woollen and silk goods, steam heaters and castings, phonograph needles, optical products, steel bars and pointed steel goods. Putnam was formed in 1855 and named after Gen. Israel Putnam. The city was chartered in 1895.

PUTNIK, RADOMIR (1847–1917), Serbian general, was born on Jan. 25, 1847, at Kraguyevats. After serving against Turkey in 1876 and 1877, and against Bulgaria in 1889, he was made deputy-chief of the general staff, and professor at the military academy in Belgrade. The intrigues and favouritism introduced by the kings, Milan and Alexander, caused him to be placed on the retired list, but in the autumn following the military revolution of 1903 he was appointed general and chief of the general staff. In 1906 he succeeded General Gruič as minister of war, and again held that office in 1912, during the period when the military convention with Bulgaria was negotiated.

On the outbreak of war with Turkey Putnik was made *voivode* or marshal (being the first holder of that title) and commander-in-chief, and was responsible for the rapid success of the Serbian arms at Kumanovo, Prilep and Monastir. It was largely owing to his vigilance and foresight that the treacherous night attack by which the Bulgarians opened the second Balkan War (June 29, 1913) failed as it did. When the World War broke out, he was undergoing a cure at an Austrian watering place, and was at first placed under arrest, being later released by special order of the emperor Francis Joseph and conveyed to the Rumanian frontier. Despite impaired health he resumed the position of Serbian generalissimo and inflicted upon the forces of General Potiorek three successive defeats—on the Yadar (Aug. 16–20), the Drina (Sept. 8–19) and at Rudnik, which ended on Dec. 14, 1914 with an Austrian rout and the complete evacuation of Serbia. Putnik retained the supreme command during the triple invasion of Serbia in Nov. 1915, and shared the retreat of the Serbs through Albania. When, however, the exiled Government established itself at Corfu, he and most of his staff were placed on the retired list. He himself withdrew to France. He died on May 17, 1917, at Nice.

PUTTEE or **PUTTIE.** The name adapted from the Hindu *patti,* bandage (Skr. *patta,* strip of cloth), for a covering from the ankle to the knee, consisting of a long narrow piece of cloth wound spirally, and fastened by a tape, though straps may be used. For infantrymen, the winding commences at the ankle, but mounted men reverse the process as the rubbing against the horse causes the tape to come undone. Their advantages over leggings are that they are not "hard" on the legs, can be used as bandages or slings in case of need, and occupy less space when not in wear. Worn by most armies except the German in 1918, they have gradually disappeared in favour of short leggings.

PUTTENHAM, GEORGE (d. 1590), the reputed author of *The Arte of English Poesie* (1589). The book was entered at Stationers' Hall in 1588, and published in the following year. The writer of *The Arte of English Poesie* was educated at Oxford, and at the age of 18 he addressed on eclogue entitled *Elpine* to Edward VI. In his youth he had visited Spain, France and Italy, and was better acquainted with foreign courts than with his own. In 1579 he presented to Queen Elizabeth his *Partheniades* (printed in a collection of ms. *Ballads* by F. J. Furnivall), and he wrote the treatise in question especially for the delectation of the queen and her ladies. He mentions nine other works of his, none of which are extant. There is no direct evidence beyond Bolton's ascription to identify the author with George or Richard Puttenham, the sons of Robert Puttenham and his wife Margaret, the sister of Sir Thomas Elyot, who dedicated his treatise on the *Education or Bringing up of Children* to her for the benefit of her sons.

Many later "poetics" are indebted to this book. The original edition is very rare. Professor Edward Arber's reprint (1869) contains a clear summary of the various documents with regard to the authorship of this treatise. The history of the Puttenhams is discussed in H. H. S. Croft's edition of Elyot's *Boke called the Governour.* There are other modern editions of the book, notably one in J. Haslewood's *Ancient Critical Essays* (1811–15).

PUTTING THE SHOT is the modern form of the ancient sport of putting the stone. First to use a shot instead of a stone competitively were British military sports groups, and later the idea was adopted by civilians.

While the weight varied from 14 lb. to 42 lb., the 16-lb. shot was the one adopted for men in Olympic games, national and international competitions. Weight for women's competition is 8 lb. In the United States a 12-lb. shot is used for high school boys' competition, ages 15–19.

Shot-putting is one of the few events in which a tremendous increase in distance was achieved by improved technique and not by improved equipment. Unlike the hammer-throwing record, which was raised by Irishmen, the upward move of the shot-put record from 30 ft. 11½ in. in 1876 to 58 ft. 10½ in. in 1950 can be attributed to a cosmopolitan group, including representatives of England, Ireland, Germany, Czechoslovakia, Poland and the United States.

The most remarkable individual improvement was that of Jack Torrance of Louisiana State university, U.S. Starting with a best distance of only 41 ft. 5 in. in 1931, he did 47 ft. 3 in. (1932); 52 ft. 10 in. (1933); and in 1934 moved the world's record to 57 ft. 1 in.—an improvement of almost 16 ft. in four years. The greatest individual achievement was by James E. Fuchs (Yale university and New York Athletic club, U.S.), who did not put the 16-lb. shot before entering Yale. In 1947 Fuchs did 49 ft. 8½ in.; 54 ft. 8⅜ in. (1948); 58 ft. 4⅜ in. (1949); and 58 ft. 10½ in. (1950). From July 28, 1949, to June 4, 1952, Fuchs put the shot 58 ft. or more 12 times outdoors and once indoors. Within six days, in 1950, he achieved distances of 58 ft. or more eight times, climaxing this series with a world's record of 58 ft. 10½ in., at Eskilstuna, Swed., Aug. 22.

The two best winning performances in Olympic games competition through the 1952 games were by Americans—56 ft. 2 in. by Wilbur M. Thompson (1948), and 57 ft. 1½ in. by Parry

O'Brien (1952), both using the Thompson technique.

According to Thompson, the principle involved in putting the spherical, solid iron or brass missile from the shoulder with one hand is acceleration—a gradual speeding up, in a straight line, of the movement across the seven-foot circle with the minimum amount of effort.

The put is started at the back of the circle by shifting the weight of the body to the right foot with good balance, left knee bent and the left toes raised so that the spikes clear the ground. Next, the left knee is brought close to the right knee and the right leg bent gradually as the hips cross the circle. This method of starting the put enables the shot-putter to be in a correct position when he reaches the centre of the circle and thus able to start lifting the shot immediately. The shot is lifted via the medium of the leg muscles, and the put must always be made upward and not outward, by a rhythmic movement of the arm muscles, which can be acquired by constant repetition.

See Frank G. Menke, *New Encyclopedia of Sports* (1947).

(H. Ar. Rn.)

PUTTKAMER, ROBERT VON (1828–1900), Prussian statesman, was born at Frankfurt-on-Oder on May 5, 1828. Puttkamer was the chosen instrument of the clerical conservative policy initiated by Bismarck when the growth of the Socialist movement made it expedient to conciliate the Catholic centre. As *Oberpräsident* of Silesia he had mitigated the rigour of the application of the "May laws," and as minister of public worship and of the interior he continued this policy. He was also the author of the ordinance of Jan. 2, 1880, on the simplification of German orthography.

As minister of the interior, Puttkamer's temper was in harmony with the view of Bismarck and the emperor William, and with their support he tried to re-establish the old Prussian system of rigid discipline from above.

On his initiative, on Jan. 4, 1882, a royal ordinance required all officials to give the government their unconditional support at political elections. He also interfered with the liberty of public meetings and attempted to suppress strike movements by force. This "Puttkamer regime" was intensely unpopular, and when the emperor Frederick III succeeded to the throne Puttkamer was forced to resign (June 8, 1888). He was largely rehabilitated under William.

Puttkamer died at Karzin, in Pomerania, on March 15, 1900.

PUTTY. Originally tin oxide in a state of fine division used for polishing glass, granite, etc., now known as "putty powder" or "polisher's putty." The term is applied to cement composed of fine powdered chalk (whiting) or oxide of lead (white lead) mixed with linseed oil, either boiled or raw. It is used for fixing sheets of glass in frames and for filling up nail holes, etc., in woodwork. The oxidation of the oil hardens the putty and when it is required to dry quickly, boiled oil and sometimes litharge and other driers are used. Putty is also a fine lime cement employed by masons.

PUVIS DE CHAVANNES, PIERRE CÉCILE (1824–1898), French painter, was born at Lyons on Dec. 14, 1824. His father was a mining engineer, the descendant of an old family of Burgundy. Pierre Puvis was educated at the Lyons college and at the Lycée Henri IV in Paris, and was intended to follow his father's profession when a serious illness interrupted his studies. A journey to Italy opened his mind to fresh ideas, and on his return to France he went to study painting first under Henri Scheffer and then under Thomas Couture. In 1852 he established himself in a studio in the Place Pigalle (which he did not give up till 1897), and there organized a sort of academy for a group of fellow students who wished to work from the living model. Puvis first exhibited in the Salon of 1850 a "Pietà." In 1852 and in the following years Puvis's pictures were rejected by the Salon, but the young painter was none the less warmly defended by Théophile Gautier and Théodore de Banville. His compositions at this early period show great variety, reflecting the influence of the Italian masters as well as of Delacroix and Couture. In 1859 Puvis reappeared in the Salon with the "Return from Hunting" (now in the Marseilles gallery). But not till he produced "Peace" and "War" did he really impress his critics, inaugurating a vast series of decorative paintings. For these two works a second-class medal was awarded to him. In 1864 he exhibited "Autumn" and "Sleep." One of these pictures is in the Lyons museum and the other at Lille. "Peace" and "War" were placed in the great gallery of the museum at Amiens, where Puvis completed their effect by painting four panels—a "Standard-Bearer," "Woman Weeping over the Ruins of her Home," a "Reaper" and a "Woman Spinning." Further decorations were ordered for the same building, and the artist presented to the city of Amiens "Labour" and "Repose." In 1865 a composition entitled "Ave Picardia Nutrix," allegorical of the fertility of the province, was added to the collection. In 1879 the city wished to complete the decoration of the building, and the painter executed the cartoon of "Ludus pro patria," exhibited in the Salon of 1881 and purchased by the state, which at the same time gave him a commission for the finished work. Meanwhile Puvis de Chavannes also painted easel pictures. To the Salon of 1870 he had sent a picture called "Harvest"; the "Beheading of John the Baptist" figured in the Great Exhibition of 1889; then followed "Hope" (1872), the "Family of Fisher-Folk" (1875) and "Women on the Seashore" (1879). Two paintings in the Palais Longchamp at Marseilles, ordered in 1867, represent "Marseilles as a Greek Colony" and "Marseilles, the Emporium of the East." After these, Puvis executed for the town hall of Poitiers two decorative paintings of historical subjects: "Radegund" and "Charles Martel." The Panthéon in Paris also possesses a decorative work of great interest by this painter, "The Life of Saint Geneviève," treated in three panels. In 1876 the department of fine arts in Paris gave the artist a commission to paint "Saint Geneviève Giving Food to Paris" and "Saint Geneviève Watching Over Sleeping Paris," in which he gave to the saint the features of Princess Cantacuzene, his wife. At the time of his death—on Oct. 24, 1898—the work was almost finished. After completing the first paintings in the Panthéon, which occupied him for three years and eight months, Puvis de Chavannes undertook to paint the staircase leading to the gallery of fine arts in the Lyons museum and took for his subjects the "Vision of the Antique," a procession of youths on horseback, which a female figure standing on a knoll points out to Pheidias; the "Sacred Grove"; and two allegorical figures of "The Rhône" and "The Saône." It was in the same mood of inspiration by the antique that he painted the hemicycle at the Sorbonne, an allegory of "Science, Art, and Letters." At the Hôtel de Ville in Paris, Puvis decorated the grand staircase and the first reception room. These works occupied him from 1889 till 1893. In the reception room he painted two panels, "Winter" and "Summer." The pictures in the Rouen museum (1890–1892) show the artist's power of conceiving a scheme to decorate a public building with beautiful human figures and the lines of landscape. Puvis, as a rule, adhered to the presentment of the nude; here, however, in response to some critical remarks, he has clad his figures in modern dress. After prolonged negotiations, begun as early as in 1891, with the trustees of the Boston library, U.S., Puvis de Chavannes accepted a commission to paint nine large panels for that building. These pictures, begun in 1895, were finished in 1898. In these works of his latest period Puvis de Chavannes soars boldly above realism.

Puvis de Chavannes was president of the National Society of Fine Arts (the New Salon). His principal pupils were Ary Renan, Paul Baudouin, J. F. Auburtin and Cottet.

See Marius Vachon, *Puvis de Chavannes* (1900); J. Buisson, "Puvis de Chavannes, Souvenirs Intimes," *Gazette des beaux-arts* (1899); L. Riotor, *Les Arts et les Lettres* (1901); A. Michel, *Puvis de Chavannes* (London, 1912). (H. Fr.; X.)

PUY, a geological term used locally in Auvergne for a volcanic hill. Most of the puys of central France are small cinder cones, with or without associated lava, while others are domes of trachytic rock, like the domite of the Puy-de-Dôme. The puys may be scattered as isolated hills, or, as is more usual, clustered together, sometimes in lines. They probably became extinct in late prehistoric time. Puys are also found in the Eifel, on the Bay of

Naples, in the Swabian Alps of Württemberg, and, as Sir A. Geikie has shown, in Scotland.

PUYALLUP, a city of Washington, U.S. It is served by the Chicago, Milwaukee, St. Paul and Pacific, the Great Northern, the Northern Pacific and the Union Pacific railways. Pop. (1950) 10,010; (1940) 7,880 by the federal census. It is famous for its berries and bulbs, and has three large fruit-canning and cooling plants. Primary crops of the Puyallup valley include raspberries, blackberries, blueberries, narcissus, daffodil and tulip bulbs, vegetables, dairy and poultry products. The western Washington agricultural experiment station of the state college is located there. Puyallup was platted on Feb. 18, 1877, by Ezra Meeker. The city was incorporated as Puyallup, which means "generous people" in Indian language, in 1890 with Meeker as mayor.

PUY-DE-DÔME, a department of central France, four-fifths of which belonged to Basse-Auvergne, one-sixth to Bourbonnais, and the remainder to Forez (Lyonnais). Area, 3,095 sq.mi. Pop. (1946), 478,876. It is bounded north by Allier, east by Loire, south by Haute-Loire and Cantal, and west by Corrèze and Creuse. The famous plain of the Limagne, watered by the Allier and its tributary, the Dore, has on its western flank the volcanic Puys and Monts Dore, while on its eastern side rises the largely granitic heights of the Forez (5,380 ft.). The Puys include a number of craters, now dead and often filled by lakes, which also occur behind lava dams in the valleys. The Puy de Sancy (6,188 ft.) is the highest crater, but the Puy de Dôme (4,806 ft.) gives its name to the department and has a meteorological observatory on its summit, once crowned by a Roman temple, the ruins of which still exist.

The climate of Puy-de-Dôme is usually very severe, owing to its high level and its distance from the sea; the mildest air is found in the northern valleys, where the elevation is least. During summer the hills about Clermont-Ferrand, exposed to the sun, become all the hotter because their black volcanic soil absorbs its rays. On the average 25 or 26 in. of rain fall in the year; in the Limagne, around which the mountains arrest the clouds, rainfall is less. Nevertheless the soil of this plain, consisting of alluvial deposits of volcanic origin, and watered by torrents and streams from the mountains, makes it one of the richest regions of France. In the highest altitudes the rainfall attains 64 inches.

About two-thirds of the inhabitants of the Puy-de-Dôme are engaged in agriculture. The Limagne yields a variety of products and the vine flourishes on its hill-sides. The high mountains provide pasture for large flocks of cows and sheep, and cheese-making is an important industry. The intermediate region is cultivated mainly for cereals, the chief of which are wheat, rye, oats and barley. Potatoes are largely grown, and peas, beans, beetroot, colza and tobacco. The Limagne produces fruit of all kinds—apricots, cherries, pears, walnuts and apples, yielding considerable quantities of cider. The department possesses considerable mineral wealth. There are important coal-mines at Brassac on the Allier, on the borders of Haute-Loire, at St. Elroy near the department of Allier, and at Bourg-Lastic on the borders of Corrèze. Peat, asphalt, bituminous schists, antimony, mispickel and argentiferous lead are also worked. Of the last named there are mines and foundries at Pontgibaud on the Sioule. Amethysts and other rare minerals are found, and there are numerous stone-quarries. Mont Dore, Royat and La Bourboule are watering places. The springs of St. Nectaire contain sodium and iron chlorides and bicarbonates. The waters of Châteauneuf (on the Sioule), also known to the Romans, contain iron bicarbonates; those of Châtelguyon, like the waters of Carlsbad and Marienbad, are also widely known, and there are many other mineral springs of varied character. Manufactures are grouped around Thiers, which produces a large amount of cheap cutlery, and Clermont-Ferrand, the capital. The textile industry includes wool-carding and making of linen cloths, bunting, clothing, manufactories for lace and for rubber (Clermont-Ferrand), sugar-works, manufactures of edible pastes and of fruit-preserves. The department exports grain, fruits, cattle, wines, cheese, wood, mineral waters, cutlery, etc. It is served by the Orléans and P.L.M. railway companies. Many thousands of the inhabitants, chiefly of the district of Ambert, leave it during winter and find work elsewhere. The department comprises 5 *arrondissements*—Ambert, Clermont-Ferrand, Issoire, Riom, Thiers—50 cantons and 473 communes. The chief towns are Clermont-Ferrand, Issoire, Thiers, Riom, Ambert, Mont-Dore-les-Bains, La Bourboule and Royat. Near Clermont-Ferrand is Mt. Gergovie (*see* GERGOVIA), the scene of the victory of Vercingetorix over Julius Caesar. Billom, Chamalières, Courpière, Orcival, St. Nectaire and St. Saturnin possess churches in the Romanesque style of Auvergne. There are interesting ruined feudal strongholds at Murols and Tournoël (near Volvic). Vic-le-Comte has a *sainte-chapelle* which is a beautiful example of the transition from Gothic to Renaissance architecture, and Aigueperse has a Gothic church of the 13th to the 15th century. Near Pontgibaud are the ruins (13th-century) of the Carthusian abbey of Port St. Marie. There are a few megalithic remains in the department.

PWLLHELI ("salt pit," or "pool"), a municipal borough, seaport and market town of Caernarvonshire, north Wales, 21 mi. S.W. of Caernarvon with station on the G.W.R. Pop. (1938) 3,578. Area 1.8 sq.mi. It has a sandy beach on the north side of Cardigan bay, on the shore of Tremadoc bay. The town was incorporated by Edward the Black Prince. Pwllheli commands a good view of the Merionethshire and Snowdon mountains.

PYANEPSIA, an ancient festival in honour of Apollo, held at Athens on the 7th of the month Pyanepsion (October). A hodge-podge of pulse was offered to Apollo. Another offering was the *eiresiōnē,* a branch of olive or laurel, bound with purple or white wool, round which were hung fruits of the season, pastries, and small jars of honey, oil and wine. Both are old pieces of rustic magic, for which many analogies can be found elsewhere. It was carried in procession to the temple of Apollo where it was suspended on the gate by a boy whose parents were both alive. The doors of private houses were similarly adorned. The branch was allowed to hang for a year, when it was replaced by a new one, since by that time it was supposed to have lost its virtue. During the procession a chant (also called *eiresiōnē*) was sung, the text of which has been preserved in Plutarch (*Theseus,* 22).

Aetiologists connected both offerings with the Cretan expedition of Theseus, who, when driven ashore at Delos, vowed a thank-offering to Apollo if he slew the Minotaur, which afterwards took the form of the *eiresiōnē* and Pyanepsia. His comrades on landing in Attica gathered up the scraps of their provisions which explains the origin of the hodge-podge.

See W. Mannhardt, *Wald- und Feldkulte,* ii., 214, for an exhaustive account of the *eiresiōnē* and its analogies; Sir J. G. Frazer, *Golden Bough,* vol. ii., pp. 48, 71; A. Mommsen, *Feste d. Stadt Athen,* p. 278. et seq.; J. E. Harrison, *Prolegomena to Greek Religion,* ch. iii.; L. R. Farnell, *Cults of the Greek States,* iv. 286.

PYAPON, a town in Burma, on the Pyapon river. Pop. (1931) 12,338. The district, formed in 1903, lies within the delta of the Irrawaddy. It is intersected by creeks and liable to inundation at high spring tides. The jungle is being reclaimed for rice, which is the sole crop. Area, 2,076 sq.mi.; pop. (1941) 385,008, showing an increase of 50,058 in the decade. The district has no railways and few roads, communication being by water. Other urban centres, which ship the rice to Rangoon, are Kyaiklat (10,658 in 1931), and Dedayè (6,778 in 1931).

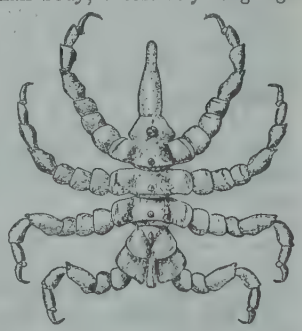
PYAT, FELIX (1810–1889), French communard, was born at Vierzon (Cher) on Oct. 4, 1810, the son of a Legitimist lawyer. Called to the bar in Paris in 1831, he threw his whole energies into journalism. The violent personalities of a pamphlet entitled *Marie Joseph Chénier et le prince des critiques* (1844), in reply to Jules Janin, brought him a six months' sojourn in La Pélagie, in the cell quitted by Lamennais. In 1848 George Sand, whom he had introduced in 1830 to the staff of the *Figaro,* now asked Ledru-Rollin to make him commissary-general of the Cher. After three months' tenure of this office he was returned by the department to the Constituent Assembly, where he voted with the Mountain, and brought forward a motion for the abolition of the presidential office. About this time he fought a duel with Proudhon, who had called him the "aristocrat of the democracy." He joined Ledru-Rollin in the attempt of June 13, 1849, after which he sought refuge in Switzerland, Belgium, and finally in England. For a glorification of regicide at the time the Orsini attempt

against Napoleon III he was brought before an English court, but acquitted, and the general amnesty of 1869 permitted his return to France, but further outbursts against the authorities compelled his return to England. The revolution of Sept. 4 brought him back to Paris, and it was he who in his paper *Le Combat* displayed a black-edged announcement of the *pourparlers* for the surrender of Metz. After the insurrection of Oct. 31, he was imprisoned for a short time. In Jan. 1871, *Le Combat* was suppressed, only to be followed by an equally virulent *Vengeur*. Elected to the National assembly, he retired from Bordeaux with Henri Rochefort and others until such time as the "parricidal" vote for peace should be annulled. He returned to Paris to join the committee of public safety, and, in Hanotaux's words, was the *âme ulcérée* of the Commune, but was blamed for the loss of the fort of Issy. He was superseded there by Delescluze, but he continued to direct the violent acts of the Commune, the overthrow of the Vendôme column, the destruction of Thiers's residence and of the expiatory chapel built to the memory of Louis XVI. He escaped across the frontier, and, though condemned to death in 1873, the amnesty of July 1880 permitted his return. He was elected to the chamber of deputies in 1888, but died at Saint-Gratien on Aug. 3, 1889.

PYATIGORSK, a town of Russia in the North Caucasus on the Podkoumok river and on a plateau 1,680 ft. above sea-level, hence its name ("five mountains"). Its sulphur springs, about 15 in number, vary from 75° to 96° F. and are used for drinking and bathing and are bottled for export. The first buildings were erected in 1812 and a great impetus was given to the town when it was linked with the Rostov-on-Don to Baku railway. Its population in 1939 was 62,875. Its springs had long been known to the Circassians of the district who addressed a petition to Ivan the Terrible in 1551 asking for protection against the Crimean Tatars. The poet M. Y. Lermontov (1814–1841) was killed here in a duel. In 1918 a skeleton, apparently Neanderthal, was reported.

See *Russ. Anthr. Journ.* (1922); "Caucasus: Ice Age," *Man,* vol. xxv (1926).

PYCNOGONIDA, or Pantopoda (rarely, Podosomata), a class of marine Arthropoda comprising about 500 known species, remotely related to the Arachnida on one side and the Crustacea on the other, but distinct from both. The Pycnogonida, or sea spiders, are characterized by a small body, excessively long legs and a subsidiary pair of egg bearing legs (ovigers) in all males but lacking in the females of some genera. There are usually eight walking legs, but species with ten legs, otherwise inseparable from their octopodous counterparts, are not uncommon, although apparently confined to the antarctic and Caribbean regions, and a 12-legged form from the antarctic is also known. In addition to the walking legs and ovigers, there may be a pair of chelate appendages (chelifores), and sensory palpi; the presence or absence of these appendages constitutes the basis of classification within the group, which includes about 50 genera divided into eight or ten families. There are no well-defined orders. Inasmuch as the Pycnogonida never have the biramous limbs of the Crustacea, or the arachnid type body consisting of a cephalothorax with six pairs of appendages and a prominent abdomen, and their chelate protonymphon larva is unique, they are best considered as a class by themselves rather than as an "appendix to the Arachnida." The occurrence of extra-legged forms is not comparable with supernumerary phenomena in other groups; it may indicate polymorphic species.



AFTER D'ARCY W. THOMPSON IN CAMBRIDGE NATURAL HISTORY (MACMILLAN & CO., LTD.)
FIG. 1.—PYCNOGONUM LITTORALE, STROM

The body of a pycnogonid consists of a cephalic segment, or head region; followed by three or four trunk somites, which may be distinctly segmented, or coalesced with the cephalic segment into a compact circular disc; and a usually small, tuberclelike abdomen, at the tip of which is the anus. The mouth is a triangular opening at the end of an elaborate suctorial appendage (proboscis), which is often much longer and larger than the body. In a typical pycnogonid (*e.g. Nymphon* or *Achelia*), the cephalic segment bears three pairs of appendages anterior and in addition to the first pair of legs: the chelifores (which may or may not be chelate); the palpi, usually flanking the proboscis, and the ovigers, which originate on the ventral surface. The extreme of reduction is found in *Pycnogonum,* which lacks both chelifores and palpi and has ovigers only in the males. There are usually four simple eyes, located in a tubercle or elaborate process on the dorsal surface of the cephalic segment, but they are often lacking in deep sea species. Because of the reduced size of the body, the digestive system has long branches into the legs, and the bulk of the gonads is also in the legs. The genital apertures are usually on the ventral surface of the second joints, but the sexual products are stored in the fourth or femoral joints of the legs. The circulatory system consists of a dorsal heart with two or three pairs of lateral ostia; there are no blood vessels. The nervous system is composed of a supra-oesophageal ganglion or "brain," and a chain of five or six ventral ganglia. There is no specialized excretory or respiratory system.

AFTER D'ARCY W. THOMPSON IN CAMBRIDGE NATURAL HISTORY (MACMILLAN & CO., LTD.)
FIG. 2.—NYMPHON STROMII, KR. MALE CARRYING EGG-MASSES ON HIS OVIGEROUS LEGS

In all species of which the habits are known, the male attaches the eggs to his ovigers in masses or clusters as they are extruded from the female, and carries them with him during the early developmental stages. In some species the larvae are then attached to hydroids, in which they form cysts, others are known to invade the medusa stage, and in many arctic and antarctic forms they remain clinging to the male until well developed. The larval stages of a Japanese species, *Nymphonella tapetis,* are parasitic in the mantle cavities of bivalve molluscs. The life cycle of the deep sea forms, especially members of the genus *Colossendeis,* is unknown.

Pycnogonids are found from the littoral zone to depths of more than 2,000 fathoms in all oceans, but are especially abundant in arctic and antarctic waters. Most species are bottom dwellers, usually living in hydroid colonies and feeding upon the soft parts and body juices of coelenterates and other soft animals, but at least two species live on the pelagic sargassum weed in mid-Atlantic, and others appear to be bathypelagic at depths of from 600 to 1000 fathoms. Some species ascend to the surface during their breeding season, swimming by treading water with their long legs. In size pycnogonids range from a spread of 3–4 mm. across the outstretched legs in such forms as the littoral *Tanystylum,* to about 50 cm. in deep sea members of the genus *Colossendeis.*

PYCNOSTYLE, the architectural term given by Vitruvius to the inter-columniation (*q.v.*) of a temple, when the distance between these columns was equal to 1½ times their diameter.

PYDNA, BATTLE OF (168 B.C.). The Roman operations in Greece having lingered on for some time, Lucius Aemilius Paullus, "one of the few Romans of that age to whom one could not offer money," was sent to hasten a decision. Arriving at Heracleum he at once seized the pass of Pythium, which compelled Perseus king of Macedonia to fall back on Pydna.

The serried ranks of the Macedonian phalanx astonished and terrified Paullus, who, however, disguised his anxiety from his men, and advanced toward his enemy. The Roman vanguard was

dispersed and one cohort almost annihilated. Once again the sarissa (pike) carried all before it, the Roman legions being forced back until they reached the hill upon which stood their camp. Here, on account of the broken nature of the ground, the phalanx became somewhat disorganized. Paullus at once sizing up the situation "commanded his men, that wherever they should see the line of the enemy present openings, they should individually rush to these spots, and insinuating themselves like a wedge into such spaces, however narrow their extent, they should fight with impetuosity" (Livy). These tactics resulted in complete success, the phalanx being disjointed and broken up into a number of separated bodies. The II legion then charged the disorganized mass of pikemen and routed it. Perseus and his cavalry fled the field leaving the infantry to be slaughtered—20,000 were killed and 11,000 made prisoners. This battle was the last fought by the phalanx. The whole campaign was only 15 days. Thus perished the empire of Alexander the Great 144 years after his death.

See Livy XLIV.; T. Mommsen, *The History of Rome*, Book III, chap. x.; H. G. Liddell, *A History of Rome* (1855). (J. F. C. F.)

PYE, HENRY JAMES (1745–1813), English poet laureate, was born in London on Feb. 20, 1745, and educated at Magdalen college, Oxford. Of all he wrote his prose *Summary of the Duties of a Justice of the Peace out of Sessions* (1808) is most worthy of record; it is based on his own experience as a magistrate at Westminster. He was made poet laureate in 1790, perhaps as a reward for his faithful support of Pitt in the house of commons. The appointment was looked on as ridiculous, and his birthday odes were a continual source of contempt. His most elaborate poem was an epic, *Alfred* (1801). He was the first poet laureate to receive a fixed salary of £27 instead of the historic tierce of Canary wine. He died at Pinner, Middlesex, on Aug. 11, 1813.

PYGMALION, (1) son of Cilix, and grandson of Agenor, king of Cyprus. He fell in love with an ivory statue he had made; Aphrodite granted life to the image, which he married (Ovid. *Metam.* x, 243). There is no ancient authority for the introduction of the name Galatea. (2) Brother of Dido (*q.v.*).

PYGMY, a term for a diminutive human being. Homer, in the *Iliad* (iii, 6) uses it of a race of tiny folk dwelling in a far southern land, whither the cranes fly when inclement winters and piercing frosts visit the northern shores. Fierce battles were often mentioned by later writers as occurring between the pygmies and cranes, and were even represented on their vases. On these the pygmies were depicted as dwarfs with large heads, negro features, close, curly hair, and sometimes armed with lances. Aristotle firmly believed in the existence of these pygmies, whom he characterized as a race of men of small stature inhabiting the marshes of upper Egypt toward the sources of the Nile. Herodotus (ii, 32), describes how five Nasamonians, while journeying through the African desert, came at last to a plain where fruit trees grew. While gathering the fruit they were seized by some dwarfish men of strange speech, who led them to a town, where dwelt people of a similar appearance, and near which a great river flowed from west to east containing crocodiles. This river was probably the Niger, and the people referred to were no doubt the ancestors of the existing pygmies of equatorial Africa. Representations of pygmies are sculptured on the tombs at Sakkarah, the Vth Dynasty, *c.* 2500 B.C. They faithfully reproduce the racial characteristics of the present race of pygmies inhabiting the Ituri and Central forests.

Pliny mentions dwarfed races in both Asia and Africa, of the Catizi dwarfs in Thrace, and a similar race in Caria. Ctesias, a century after Herodotus, described a race of pygmies in the heart of India, as black and ugly, and only two *pygmai* in height. The Chinese author, Chao Fu-Kua, in the beginning of the 13th century, described a tribe of black pygmies dwelling in the Philippine Islands, called Hai-tan, small in size, with round, yellow eyes, curly hair, and with the teeth showing through their lips, no doubt the ancestors of the present Aëtas. The existing pygmy races are divided into two groups: (*a*) the African pygmies, Negrillos, (*b*) the Asiatic pygmies, Negritos (*q.v.*).

PYLE, HOWARD (1853–1911), U.S. artist and writer, was born at Wilmington, Del., on March 5, 1853. He was a pupil of the Art Students' league, New York, and first attracted attention by his line drawings after the manner of Albrecht Dürer. His brilliant work as an illustrator made him one of the foremost of American artists, his drawings to illustrate American colonial life, particularly in New England and New Amsterdam, being especially noteworthy; and he published a number of books of fiction, written and illustrated by himself. He also became prominent in decorative painting, his works including "The Battle of Nashville" for the capitol at St. Paul, Minn., and "The Landing of Carteret" for the Essex county court house, Newark, N.J. At his home in Wilmington, Del., he established a school of art, instruction being gratuitous, and many successful American illustrators were educated there. In 1907 Howard Pyle was elected a member of the National Academy of Design. He died in Florence on Nov. 9, 1911.

PYLON, in architecture, originally a gate, but in modern usage reserved to the huge truncated pyramidal forms, crowned with cornices, that flanked the entrances to Egyptian temples. The term is also applied to any similar large masses of masonry, often decorated with sculpture or architectural forms, used to flank the entrance to an avenue, a plaza or a bridge—especially a suspension bridge. (*See* BRIDGES; EGYPTIAN ARCHITECTURE.) Also a tower, usually of steel, to support a telegraph, telephone or electric line over an extended span. In aeronautics, a post or tower indicating a prescribed course of flight.

PYLOS (mod. Navarino), a town and bay on the west coast of Messenia, noted chiefly for the part it played in the Peloponnesian War. The bay, roughly semicircular, is protected by the island of Sphacteria (mod. Sphagia), more than 2½ mi. long. To the north lies the lagoon of Osman Aga. North of Sphagia is the rocky headland of Pylos or Coryphasium, called in modern times Palaea-Navarino or Palaeokastro, from the Venetian ruins on its summit. Most scholars have identified this with the Homeric Pylos, the home of Neleus and Nestor, and a cave on the north slope of Coryphasium is pointed out as that in which Hermes hid the stolen cattle of Apollo. But this view presents considerable difficulties, and Strabo (viii, 348, *et seq.*) argued that the Pylos of Nestor must be the place of that name in Triphylia, now known to have been an important prehistoric site. After the Dorian migration Pylos declined, and it is referred to by Thucydides (iv, 3) as a deserted headland in 425 B.C. In May of that year, the seventh of the Peloponnesian War, the Athenians sent an expedition to Sicily under command of Eurymedon and Sophocles. With them was the general, Demosthenes, who landed at Coryphasium with a body of Athenian troops and hastily fortified it. The Spartans, who were then invading Attica, withdrew their forces and attacked Pylos vigorously by sea and land, but were repulsed, and the Athenians were enabled by the arrival and victory of their fleet to blockade on the island of Sphacteria a body of 420 Spartiates with Helots. Their resistance was overcome by a rear attack directed by a Messenian, who led a body of men by a difficult path along the cliffs on the east, and the 292 Spartan survivors laid down their arms 72 days after the beginning of the blockade. Their surrender made a deep impression on the whole Greek world, which had learned to regard a Spartan surrender as inconceivable. Though Pylos should have been ceded to Sparta under the peace of Nicias (421 B.C.) it was retained by the Athenians until the Spartans recaptured it early in 409 B.C. (Diodorus xiii, 64).

In the middle ages the name Pylos was replaced by that of Avarino (Ἀβαρῖνος) or Navarino, derived from a body of Avars who settled there; the current derivation from the Navarrese company, who entered Greece in 1381 and built a castle at this spot, cannot now be maintained (*Eng. Hist. Review*, xx, 307, xxi, 106; *Hermathena*, xxxi, 430 *sqq.*). From 1498 to 1821 Navarino was in the hands of the Turks, save at two periods when it was held by the Venetians, who named it Zonklon. (*See* NAVARINO, THE BATTLE OF.)

Though differing on many points, they agree in thinking (1) that the island of Sphagia is the ancient Sphacteria, Palaeokastro the ancient Coryphasium or Pylos; (2) that in 425 B.C. the lagoon of Osman Aga was navigable and communicated by a navigable channel with the Bay of Navarino; (3) that Thucydides, if the ms. reading is correct, underestimates the length of the island, which he gives as 15 stades instead of 24 (nearly 3 mi.), and also the breadth of the southern channel between it and the mainland. *Cf. J.H.S.*, xx, 14 *sqq.*, xxvii, 274 *sqq.*, and Frazer's summary (*op. cit.* v, 608 *sqq.*). (M. N. T.; X.)

PYM, JOHN (1584–1643), English statesman, son and heir of Alexander Pym, of Brymore, Somersetshire, a member of an ancient family which had held this seat in direct male descent from the time of Henry III. He matriculated as a commoner at Broadgates hall (now Pembroke college), Oxford, in 1599, and entered the Middle Temple in 1602. He became receiver-general of the king's revenue for Wilts., and was returned to parliament as member for Calne in 1614 and again in 1621. To the committee appointed to consider the state of religion he made his first great speech on Nov. 28, 1621; he spoke in defense of maintaining the disabilities of Roman Catholics on political grounds, and moved for a special commission for the suppression of recusancy. Pym was a chief promoter of the petition which incurred James's violent displeasure, and of the commons' answer defending their privileges, which was afterward torn from the records by the king's own hand. On the dissolution of parliament which immediately followed, Pym, with other "ill-tempered spirits," was arrested in Jan. 1622, and was confined first to his house in London, and then to Brymore. He associated himself with the party of Francis, 4th earl of Bedford, was returned for Tavistock in 1624, and represented this borough in all the ensuing parliaments.

On May 8, Pym was manager of Buckingham's impeachment. In the third parliament of Charles I, in 1628, Pym overruled Eliot in deciding that Buckingham's impeachment should now be subordinated to the struggle on general grievances. He zealously pushed on the Petition of Right, resisting the clause added by the Lords to safeguard the king's "sovereign power," declaring that "he knew not what it was." He carried up to the lords the impeachment of Roger Manwaring, and delivered a famous speech (June 9) in which he expounded the fundamental principles which guided his policy.

His name is not mentioned as actively resisting Charles's arbitrary government during the 11 years which followed the dissolution of 1629. It has not been proved that Pym, with Hampden and Cromwell, actually embarked for New England and was prevented from sailing by orders from the government. Pym himself was directly interested in the colonies, being patentee of Connecticut and Providence, and of the latter company also treasurer, and there can be little doubt that like other leaders of the opposition, he regarded the United States as a possible refuge.

Short Parliament.—On the assembly of the short parliament on April 13, 1640, Pym was the acknowledged leader. "Whilst men gazed upon each other," says Clarendon (*Hist.* ii, 68), "looking who should begin (much the greater part having never before sat in parliament), Mr. Pym, a man of good reputation . . . who had been as long in these assemblies as any man there living, broke the ice." On April 17 he spoke for nearly two hours on the national grievances, pointed out the practical injury inflicted on commerce and every sort of enterprise including colonial expansion by illegal and arbitrary taxation, and concluded by asking the lords to join in finding out causes and remedies. His words made a deep impression. On April 27 he resisted the grant of supply, and when the lords passed a resolution that supply should precede the discussion of grievances, Pym, as manager of the commons on May 1, read them a severe lecture on the breach of privilege they had committed. Finally, on the 4th, it was resolved that Pym should next day petition the king to make terms with the Scots, to avoid which Charles summarily dissolved the parliament.

All the energies of Pym were now concentrated on obliging Charles to summon another parliament. He was the author of the petition of the 12 peers to the king for redress of grievances and for calling a new parliament, and he was the promoter of the petition signed by 10,000 citizens of London. In company with Hampden he rode through the provinces, rousing and organizing public opinion. Meanwhile Charles's attempt to implicate Pym in treasonable communications with the Scots failed.

Long Parliament.—When the king was forced to call the long parliament (Nov. 3), Pym was its acknowledged author and leader. On Nov. 7 he moved for a sub-committee to examine into Strafford's conduct in Ireland. The latter's sudden arrival at London on the 9th with the intention of instantly impeaching the popular leaders of treason was met by Pym with corresponding quickness and resolution. On the 11th, after a debate of four hours in the commons, by his directions with locked doors, he carried up Strafford's impeachment to the lords, and rendered him at once powerless.

On Dec. 6 he moved the impeachment of Laud. He was the chief promoter of the case against Strafford, while the attempts of the queen to gain him over were without result, and Jan. 28, 1641 he brought up to the lords the list of charges. To the attainder, which was at this stage resolved upon, he was opposed (since he clung to the more judicial procedure by impeachment), but when overruled he supported it, at the same time procuring that the legal arguments should not be interrupted. He delivered his final speech on April 13, a great oratorical performance, when he again appealed to the Elizabethan political faith and to that of Bacon, who had so severely censured any action which divided the king from the nation. The man who violated this union was guilty of the blackest treason. "Shall it be treason," he asked, "to embase the king's coin though but a piece . . . of sixpence . . . and not to embase the spirits of his subjects; to set a stamp and character of servitude upon them?" Toward the end of his tremendous indictment of Strafford, Pym broke down, fumbled among his papers, and lost the thread of his argument. But his temporary failure did not diminish the force and effect of his words, all the more impressive because actually spoken in the presence of the sovereign. "I believe," wrote Baillie (*Letters*, i. 348) "the king never heard a lecture of so free language against his idolized prerogative."

Attempts were now once more made to gain over Pym to the administration. He had two interviews with the king, but without result, and Charles again determined to resort to force. On May 2 he endeavoured to get possession of the tower. On the 3rd the Protestation, on Pym's motion, was taken by the commons within closed doors, and afterward circulated in the country, and on the 5th Pym disclosed the army plot. These incidents decided the struggle and Strafford's fate. Pym also took the lead in the religious controversy. During the dispute between the two houses on this question on Feb. 8–9, 1641, while supporting the London petition for the abolition of the bishops, he had declared his opinion that "it was not the intention of the house to abolish episcopacy or the Book of Common Prayer, but to reform both wherein offence was given to the people." This, no doubt, expressed his real intentions and policy. When, however, it became clear that the bishops were merely the nominees of the king to carry out "innovations in religion" and preach arbitrary government, Pym was easily persuaded to support their abolition, and voted in opposition to the moderate party for the *Root and Branch* Bill of May 1641, and again for taking away their votes in October. But in his "Vindication," published in March 1643, he especially states that his action with regard to the bishops in "no way concluded me guilty of revolt from the orthodox doctrine of the Church of England."

The first act in the great political struggle had ended in the complete triumph of Pym. His chief care now was to defend the parliament from violence, since this was the only method of retaliation left at the king's disposal, and on Nov. 22 he made a great speech on the Grand Remonstrance, of which he was the chief promoter, when he referred to plots "very near the king, all driven home to the court and popish party."

Charles returned on the 25th. He immediately substituted a force commanded by Dorset for the guard already placed at Westminster, but was compelled to withdraw it, and on Pym's motion the house appointed its own watch. Charles appointed Lunsford to the tower, rejected the Grand Remonstrance and the Impressment bill, and began to assemble an armed force. In consequence Pym urged, but unsuccessfully, on Dec. 30 the summoning of the train-bands to guard the parliament, and moved the impeachment of the bishops, who had declared the proceedings of the parliament to be sinful and illegal. At the critical moment, however, Charles wavered. He renewed his offer to Pym of the exchequer on Jan. 1, 1642, and on his refusal, he determined on the impeachment of the five members on Jan. 3. But these had been forewarned of the king's plans, and when on the 5th he

entered the house of commons with an armed band to seize them, they had removed themselves in safety. (*See* LENTHALL, WILLIAM.) Charles's first look on entering was for his great opponent, and he was greatly disconcerted at not finding him in his usual place. To his question "Is Mr. Pym here?" there was no answer, and nothing remained but to retreat with his mission completely unachieved. The second act in the great national drama had thus, as the first, ended in a victory for Pym. On the 11th, with the other members, he was escorted in triumph back to Westminster, and while the other four stood uncovered, Pym returned thanks from his place to the citizens.

Civil War.—When war broke out, Pym remained at headquarters in control of the parliament and executive, and on July 4 was appointed to the committee of safety which directed the movements of the parliamentary forces. His attitude was firm but moderate. He opposed the attempt to prevent Colepepper giving the king's message to the house on Aug. 27. When Charles declined to receive the petition of parliament and advanced on London, Pym proposed (Oct. 20) the parliamentary covenant, and that those who refused it should be "cast out of the house." He succeeded in overcoming the opposition in the city to the heavy taxation now imposed. After repeated efforts to secure peace had failed, he proposed in order to carry on the war an excise, hitherto unknown in England, which met with the same violent hostility afterwards aroused by Walpole's scheme. In March he published a "Declaration and Vindication" of his public conduct, in which he threw the whole blame of the appeal to arms on the opposite party, and expressed his fidelity to the Church and constitution. In May he entered, together with the other leaders, into resultless negotiations with the queen, and on the 23rd he took up her impeachment to the lords. In June he reported on Waller's plot, which exposed the insincerity of Charles's negotiations, and on June 26 wrote a "sharp letter" to Essex on his inaction. In July, after the defeat at Adwalton Moor, he prevented the house from again initiating negotiations for peace, which he declared "full of hazard and full of danger," and on Aug. 3, after having visited Essex at Kingston, persuaded him to separate himself from the peace propositions of the Lords and to march to relieve Gloucester. He thus incurred the hatred of the peace party, and on Aug. 9 a mob of women surrounded the house calling for Pym's destruction, and were not dispersed without some bloodshed.

Pym had already proposed (Jan. 3) to the house an alliance with the Scots, and the Royalist victories now induced parliament to consent to what had before been rejected. The establishment of Presbyterianism was accepted by Pym as a disagreeable necessity, and he was one of the first to take the covenant (Sept. 25). This alliance, which was afterward destined to have so decisive an influence on the military campaign, and was the first occasion on which the two nations had united in public action, closes Pym's career. He was made master of the ordnance on Nov. 8, but died Dec. 8 at Derby House. He received a public funeral in Westminster Abbey, whence his body was ejected at the Restoration. A sum of £10,000 was voted by the parliament to pay Pym's debts and provide for his family. In 1614 Pym married Anne Hooke, or Hooker (d. 1620), by whom he had five children, including sons, Alexander, who died unmarried, and Charles, who was created a baronet; this title, together with Pym's male line, became extinct in the person of Pym's grandson Charles in 1688. Brymore then passing to his sister Mary, wife of Sir Thomas Hales.

Character.—Pym had little of the Puritan in his character or demeanour. His good humour, humanity and cheerfulness in all circumstances, "his pleasant countenance and sweet behaviour," were marked characteristics; the aspersions, however, on his morals, as well as the accusations of bribery, are completely unsubstantiated and discredited. Pym's eloquence lay rather in the clearness of his expression and in the depth and solidity of his ideas than in the more showy arts of oratory.

The article on Pym by S. R. Gardiner, in the *Dict. Nat. Biog.* with its references to authorities, must be supplemented by the same author's *Hist. of England and of the Civil War.* Pym's life has also been written at length by J. Forster in Lardner's *Cabinet Cyclopaedia, Eminent British Statesmen,* vol. iii., and by Wood in *Ath. oxon.* iii. 72, who adds a list of Pym's printed speeches. His character, drawn by Clarendon, *Hist.* iii. 30 and vii. 409, is inaccurate and obviously prejudiced. See also J. Forster's *Grand Remonstrance, Arrest of the Five Members, Life of Sir J. Eliot;* Verney's *Notes of the Long Parliament;* Whitelocke's *Memorials* (needing corroboration of other authorities); R. Baillie's *Letters; Eng. Hist. Rev.* xvii. 736; Rushworth's *Collections; Thomason Tracts,* E 153 (10), 63 (8), 172 (14), 164 (3), 200 (13) (26) (37) (49) (65), 199 (24) (49), 78 (13); *Somers Tracts* iv. 217, 355, 461, 466; *Affaniae* and *Death's Sermon,* by C. Fitzgeffrey; *Add. MSS.* Brit. Mus. 14,827; 11,692; *Lords and Commons Journals.* There are a large number of references to Pym in *Calendars of State Papers Dom.* 1619–1643, and *Colonial Series* 1574–1660, and in the *Hist. MSS. Comm. Series;* but the supposed notebook of Pym mentioned in *Rep.* x. app. vi. 82, has been shown by Gardiner to be that of another person (*Eng. Hist. Rev.,* Jan. 1895, p. 105).

PYORRHOEA is a term used to designate any one of a group of diseases (periodontoclasia or pyorrhoea alveolaris) which attack the gums and bone around the teeth. They include ulatrophia (recession of the gums), gingivitis (inflammation of the gums), alveolar resorption (wasting of the bony socket), pericementoclasia (pus pocket formation). Vincent's gingivitis, erroneously called Vincent's angina, also trench mouth, is an acute gingivitis caused by the fusiform bacillus and spirochaete of Vincent. It is the only type of periodontoclasia which is communicable. These diseases have a direct sequential relationship, although they do not always occur in the same order. A typical case may begin as recession associated with slight alveolar resorption: later it merges into gingivitis with advancing alveolar resorption; finally it develops a pus pocket (pericementoclasia), due to the detachment of the gum from the root, and still more advanced alveolar resorption. Unless checked by correct treatment this results in the loss of the tooth.

Knowledge as to the cause of periodontoclasia, while still incomplete, has advanced so far that rational treatment is now possible, and, in skilful hands, success is obtainable in nearly all cases. While infection plays a prominent part, the important factor is some influence which depresses the resistance of the tissues, thereby making infection possible. In a large percentage of cases the important depressant is an inequality of the biting surfaces of the teeth known as traumatic occlusion, resulting in unequal distribution of pressure when the jaws are brought together. Deposits of tartar, long regarded as the important factor, now only share the responsibility. Improper diet is regarded as important in the causation of periodontoclasia. This is apparently due to a failure to develop strong, resistant, supporting tissues for the teeth, because of dietary deficiencies. After the disease has become established dietary improvement is relatively ineffective.

Treatment includes the following, given in the order of their usual importance: equalizing functional stresses; raising local resistance by massage of the gums; removal of deposits of tartar, etc.; maintaining cleanliness; and building up general resistance by attention to nutrition. Preventive treatment follows the same lines, with special emphasis on stimulating the blood supply by tooth-brush massage. Orthodontic treatment, by helping to equalize functional stresses, helps in treatment and prevention.

Foci of infection may develop in the later stages of the disease, owing to the absorption of toxic material from the pus-pockets into the circulation. Also when the pocket extends to the end of the root, a typical abscess is produced. Advanced pyorrhoea or periodontal disease may usually be detected in the X-ray film, which registers the resorption of alveolar bone accompanying this disease. (J. O. McC.; P. R. S.)

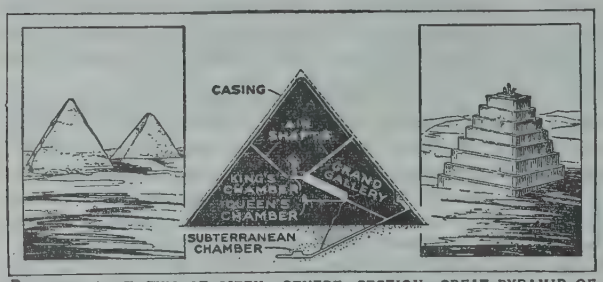
PYRAMID, the name for a class of buildings, first taken from a part of the structure,[1] and mistakenly applied to the whole of it by the Greeks, which has now so far acquired a more definite meaning in its geometrical sense, that it is desirable to employ it in that sense alone. A pyramid therefore should be understood as meaning a building bounded by a polygonal base and plane triangular sides which meet in an apex. (For figures of geometrical pyramids *see* CRYSTALLOGRAPHY, and for their mensuration *see* MENSURATION.) Such a form in architecture is best known in Middle Egypt, during the period from the IVth to the XIIth Dynasty (before 3000 B.C.)—having square bases and angles of about 50°. In other countries various modifications of the tumulus, barrow or burial-heap have arisen which have come near to this type; but these when formed of earth are usually circular, or if square have a flat top, and when built of stone are always in steps or terraces.

The origin of the pyramid type has been entirely explained by the discovery of the various stages of development of the tomb. In prehistoric times a square chamber was sunk in the ground, the dead placed in it, and a roof of poles and brushwood overlaid with sand covered the top. The Ist Dynasty kings developed a wooden lining to the chamber; then a wooden chamber free-standing in the pit, with a beam roof, then a stairway at the side to descend; then a pile of earth held in by a dwarf wall over it. By the IIIrd Dynasty this dwarf wall had

[1] The vertical height was named by the Egyptians *pir-em-us* (*see* E. Revillout, *Rev. Ég.,* 2nd year, 305–309), hence the Greek form *pyramis,* pl. *pyramides* (Herod.), used unaltered in the English of Sandys (1615), from which the singular *pyramid* was formed.

expanded into a solid mass of brickwork, about 280 by 150 ft. and 33 ft. high. This was the *mastaba* type of tomb, with a long, sloping passage descending to the chamber far below it. This pile of brickwork was then copied in stonework early in the IIIrd Dynasty (Saqqara). It was then enlarged by repeated heightening and successive coats of masonry. And lastly a smooth casing was put over the whole, and the first pyramid appeared (Medum).

The pyramids were each begun with a definite design for their



PYRAMID. LEFT: TWO AT GIZEH; CENTRE: SECTION, GREAT PYRAMID OF KHUFU, GIZEH, *c.* 3000 B.C.; RIGHT: ASSYRIAN

size and arrangement; this is plainly seen in the two largest, where continuous accretion (such as Lepsius and his followers propound) would be most likely to be met. Any section of these buildings shows how impossible it would have been for the passages to have belonged to a smaller structure (Petrie, 165). The supposition that the designs were enlarged so long as the builder's life permitted, was drawn from the compound mastabas of Saqqara and Medum; these are, however, quite distinct architecturally from true pyramids.

Around many of the pyramids peribolus walls may be seen, and it is probable that some enclosure originally existed around each of them. At the pyramids of Gizeh the temples attached to these mausolea may be still seen. As in the private tomb, the false door which represented the exit of the deceased person from this world, and towards which the offerings were made, was always on the west wall in the chamber, so the pyramid was placed on the west of the temple in which the deceased king was worshipped. The temple being entered from the east (as in the Jewish temples), the worshippers faced the west, looking towards the pyramid in which the king was buried.

The pyramid was never a family monument, but belonged—like all other Egyptian tombs—to one person, members of the royal family having sometimes lesser pyramids adjoining the king's (as at Khufu's); the essential idea of the sole use of a tomb was so strong that the hill of Gizeh is riddled with deep tomb-shafts for separate burials, often running side by side 60 or 80 ft. deep, with only a thin wall of rock between; and in one place a previous shaft has been partially blocked with masonry, so that a later shaft could be cut partly into it.

The usual construction of pyramids is a mass of masonry composed of horizontal layers of rough-hewn blocks, with a small amount of mortar; and this mass in the later forms became more and more rubbly, until in the VIth Dynasty it was merely a system of retaining walls of rough stones and mud, filled up with loose chips, and in the XIIth Dynasty the bulk was of mud bricks. There was always on the outside a casing of fine stone, elaborately finished, and very well jointed; and the inner chambers were of similarly good work. Indeed, the construction was in all cases so far sound that, had it not been for the spite of enemies and the greed of later builders, it is probable that every pyramid would have been standing in good order at this day. The casings were of massive blocks, usually greater in thickness than in height. Inside each pyramid, always low down, and usually below the ground level, was built a sepulchral chamber; this was reached in all cases by a passage from the north, sometimes beginning in the pyramid face, sometimes descending into the rock on which the pyramid was built in front of the north side. This chamber, if not cut in the rock altogether (as in Menkaura's), or a pit in the rock roofed with stone (as in Khafra's), was built between two immense walls which served for the east and west sides, and between which the north and south sides and roofing stood merely in contact, but unbonded. The gable roofing of the chambers was formed by great sloping slabs of stone, projecting from the north and south walls, on which they rested without pressing on each other along the central ridge; thus there was no thrust, though it had been provided for in the sloping form of the roof, so as to delay as long as possible the collapse of the chamber. This is best seen in the pyramid of Pepi (Petrie), opened from the top right through the roof. The roofing is sometimes of more than one layer; in Pepi's pyramid it is of three layers of stone beams, each deeper than their breadth, resting one on another, the thirty stones weighing more than 30 tons each. In the king's chamber (Gizeh) successive horizontal roofs were interposed between the chamber and the final gable roof, and such may have been the case at Abu Roash (Howard Vyse).

The passages which led into the central chambers have usually some lesser chamber in their course, and are blocked once or oftener with massive stones. In all cases some part, and generally the greater part, of the passages slopes downwards, usually at an angle of about 26°, or 1 in 2. These passages appear to have been closed externally with stone doors turning on a horizontal pivot, as may be seen at South Dahshur. This suggests that the interiors of the pyramids were accessible to the priests, probably for making offerings.

The pyramid of Medum was the first true pyramid. It was begun as a mastaba. This mastaba was then enlarged by heightening it and adding a coating, and this process, repeated seven times, resulted in a high stepped mass of masonry. Such had been made before, at the step pyramid of Saqqara; but for the first time it was now covered with one uniform slope of masonry from base to top, and a pyramid was the result. The chamber is peculiar for being entered by a vertical shaft in the floor. The great pyramid of Gizeh (Khufu's) is very different in its internal arrangements from any other. The pyramid covers upwards of 13 ac. and is about 150 ft. higher than St. Paul's cathedral. The greater number of passages and chambers, the high finish of parts of the work and the accuracy of construction all distinguish it. The chamber which is most normal in its situation is the subterranean chamber; but this is quite unfinished. The upper chambers, called the "king's" and "queen's," were completely hidden, the ascending passage to them having been closed by plugging blocks, which concealed the point where it branched upwards out of the roof of the long descending passage. Another passage, which in its turn branches from the ascending passage to the queen's chamber, was also completely blocked up. The object of having two highly-finished chambers in the mass may have been to receive the king and his co-regent (of whom there is some historical evidence) and there is very credible testimony to a sarcophagus having existed in the queen's as well as in the king's chamber. The accuracy of work is such that the four sides of the base have only a mean error of $\frac{6}{10}$ in. in length and 12″ in angle from a perfect square.[1]

The second pyramid of Gizeh, that of Khafra, has two separate entrances (one in the side, the other in the pavement) and two chambers (one roofed with slabs, the other all rock-hewn); these chambers, however, do not run into the masonry, the whole bulk of which is solid so far as is known. This pyramid has a part of the original casing on the top; and it is also interesting as having the workmen's barracks still remaining at a short distance on the west side, long chambers capable of housing about 4,000 men. The third pyramid, that of Menkaura, was cased around the base with red granite for the 16 lowest courses. Its design has been enlarged at one bound from a small pyramid (such as those of the family of Khufu) to one eight times the size, as it is at present, the passages needed therefore to be altered. But there is no sign of gradual steps of enlargement: the change was sudden. The basalt

[1]With respect to the construction of this and other pyramids, *see* Howard Vyse; on measurements of the inside of the great pyramid and descriptions, *see* Piazzi Smyth; and on measurements in general mechanical means, and theories, *see* Petrie.

Place	King	Date B.C.	Side of Base	Error	Angle	Height	Azimuth

Dahshur S.	?	?	7,459·0 in.	3·7	43° 5′ / 55° 1′	4,134 in.	9′ 12″ W.
Dahshur Small	?	?	2,064·6 in.	1·1	44° 34′	1,017 in.	10′ 12″ W.

sarcophagus of this pyramid was ornamented with the panel decoration found on early tombs, unlike the granite sarcophagi of the two previous pyramids, which are plain. Unhappily it was lost at sea in 1838.

Farther south are the pyramids of Abusir, described in the work of Col. Howard Vyse, and since excavated by the Germans. Next come those of Saqqara. The construction of the step pyramid or cumulative mastaba has been noticed above; its passages are very peculiar and intricate, winding around the principal chamber, which is in the centre, cut in the rock, very high, and with a tomb-chamber built in the bottom of it, which is closed with a great plug of red granite. A doorway faced with glazed tiles bearing the name of King Neter-khet of the IIIrd Dynasty existed here; the tiles were taken to Berlin by Lepsius. Beyond these come the pyramids of Dahshur, which are in a simple and massive style, much like those of Gizeh. The north pyramid of Dahshur has chambers roofed like the gallery in the great pyramid by successive overlappings of stone, the roof rising to a great height, with no less than 11 projections on each side. The south pyramid of Dahshur has still the greater part of its casing remaining, and is remarkable for being built at two different angles, the lower part being at the usual pyramid angle, while the upper part is but 43°. Beyond the Memphitic group are the scattered pyramids of Lisht (Senusert I.), Illahun (Senusert II.) and Howara (Amenemhat III.), and the earliest pyramid of Medum (Sneferu). Illahun is built with a framework of stone filled up with mud bricks, and Howara is built entirely of mud bricks, though cased with fine stone like the other pyramids.

The dimensions of the pyramids that are accurately known (as shown in table above) are in inches.

The first two closely agree to the proportion of 7 high on 11 base, approximately the ratio of a radius to its circle. And on dividing the base at Medum by 11 the modulus is 515·64, and the base of Khufu÷11 is 824·44. These moduli are 25 cubits of 20·625 and 40 cubits of 20·611; so it appears that the form was of the same type, but with moduli of 25 and 40 cubits respectively.

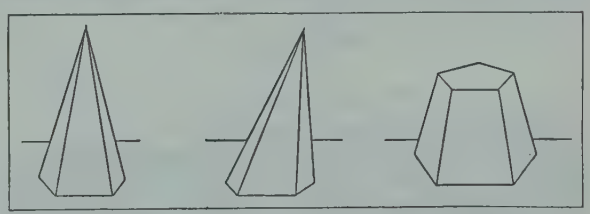
Beyond these already described there are no true pyramids, but we will briefly notice those later forms derived from the pyramid. At Thebes some small pyramids belong to the kings of the XIth Dynasty; the tomb-chamber is in the rock below. The size is under 50 ft. square. These are not oriented, and have a horizontal entrance, quite unlike the narrow pipe-like passages sloping down into the regular pyramids. (*See* Mariette, in *Bib. arch. trans.* iv. 193.) In Ethiopia, at Gebel Barkal, are other so-called pyramids of a very late date. They nearly all have porches; their simplicity is lost amid very dubious decorations; and they are not oriented. They are all very acute, and have flat tops as if to support some ornament. The sizes are very small, varying from 23 to 88 ft. square at Gebel Barkal and 17 to 63 ft. square at Meroe. The interior is solid throughout, the windows which appear on the sides being useless architectural members. (*See* Hoskin's *Ethiopia*, 148, etc.) The structures sometimes called pyramids at Biahmu in the Fayum have no possible claim to such a name; they were two great enclosed courts with sloping sides, in the centres of which were two seated statues raised on pedestals high enough to be seen over the walls of the courts.

Not one fragment of early inscription is known on the casing of any pyramid, either *in situ* or broken in pieces. Large quantities of travellers' "graffiti" doubtless existed, and some have been found on the casing of the great pyramid; these probably gave rise to the accounts of inscriptions, which are expressly said to have been in many different languages.

The mechanical means employed by the pyramid-builders have been partly ascertained. The hard stones, granite, diorite and basalt were in all fine work sawn into shape by bronze saws set with jewels (either corundum or diamond), hollows were made (as in sarcophagi) by tubular drilling with tools like our modern diamond rock-drills. (W. M. F. P.)

See Colonel Howard Vyse, *Operations at the Pyramids* (1840); Prof. C. Piazzi Smyth, *Life and Work at the Great Pyramid* (1867); W. M. Flinders Petrie, *Pyramids and Temples of Gizeh* (1883); M. D. Fraser, *The Pyramids* (Glasgow, 1894); H. Borchardt, *Die Pyramiden* (1911); M. Edgar, *The Great Pyramid* (Glasgow, 1924).

PYRAMID, in geometry, a polyhedron of which one face, called the base, is any polygon and the other faces (the lateral faces) are triangles with one vertex in common. The intersections of the lateral faces are called the lateral edges of the pyramid, and their common vertex is called the vertex of the pyramid. The perpendicular distance from the vertex to the plane of the base is called the height or altitude of the pyramid. If the base is a regular polygon the centre of which coincides with the foot of the perpendicular from the vertex to the base, the pyramid is called a regular pyramid. As in the case of prisms (*q.v.*), pyramids are classified according to their bases. The portion of a



REGULAR PYRAMID, OBLIQUE PYRAMID, AND FRUSTUM OF PYRAMID

pyramid and a plane cutting all the lateral edges is called a truncated pyramid; and if the cutting plane is parallel to the base, the truncated pyramid becomes a frustum of a pyramid. The volume of a pyramid with base B and altitude a is $\frac{1}{3}aB$. The volume of a frustum of a pyramid with bases B and B' and altitude a is $\frac{1}{3}a(B+B'+\sqrt{BB'})$. *See* SOLIDS, GEOMETRIC.

PYRAMIDION (diminutive of "pyramid"), an architectural term for the copper-gilt casing covering the apex of an obelisk; also its upper termination of pyramidal form.

PYRAMUS AND THISBE, the hero and heroine of a Babylonian love story told by Ovid (*Metam,* iv, 55–465). Their parents refused to consent to their union, and the lovers used to converse through a chink in the wall separating their houses.

At last they resolved to flee together, and agreed to meet under a mulberry tree near the tomb of Ninus. Thisbe was the first to arrive, but, terrified by the roar of a lion, took to flight. In her haste she dropped her veil, which the lion tore to pieces with jaws stained with the blood of an ox. Pyramus, believing that she had been devoured by the lion, stabbed himself. Thisbe returned to the rendezvous, and finding her lover mortally wounded, put an end to her own life. From that time the fruit of the mulberry, previously white, was always black.

See G. Hart, *Die Ursprung und Verbreitung der Pyramus-und-Thisbesage* (1889–92).

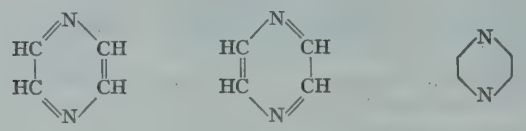
PYRARGYRITE, a mineral consisting of silver sulphantimonite, Ag_3SbS_3, known also as dark red silver ore, an important source of the metal. It is closely allied to, and isomorphous with, the corresponding sulpharsenite known as proustite or light red silver ore. "Ruby silver" or red silver ore (Ger. *Rotgültigerz*) was mentioned by G. Agricola in 1546, but the two species were completely distinguished by J. L. Proust in 1804.

The colour of pyrargyrite is usually grayish black and the lustre

metallic-adamantine; large crystals are opaque, but small ones and thin splinters are deep ruby red by transmitted light; hence the name, from Gr. πῦρ (fire) and ἄργυρος (silver). The streak is purplish red, thus differing markedly from the scarlet streak of proustite and affording a ready means of distinguishing the two minerals. The mineral occurs in metalliferous veins with calcite, argentiferous galena, native silver, native arsenic, etc. The best crystallized specimens are from St. Andreasberg in the Harz, Freiberg in Saxony and Guanajuato in Mexico. It is not uncommon in many silver mines in the United States, but rarely as distinct crystals; and it has been found in Cornish mines.

PYRAZINES, Piazines or Paradiazines, in organic chemistry, nitrogenous compounds containing a ring composed of four carbon atoms and two nitrogen atoms, the latter being at opposite ends of the ring in the so-called "*para*-position."

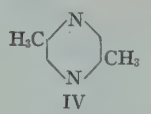
Pyrazine, $C_4H_4N_2$, crystallizes from water in colourless prisms having a heliotrope odour; it melts at 55° C. and boils at 115° C. Its structure, which is analogous to that of benzene (*q.v.*), may be described as a resonance hybrid between I and II (*see* Resonance).



I II III

As with benzene, the structure is commonly expressed by the conventional symbol III.

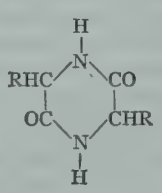
In general the pyrazines are obtained by eliminating water and hydrogen from α-aminoaldehydes or α-aminoketones (two molecular proportions in each case). α,γ-Dimethylpyrazine or ketine (formula IV), a liquid boiling at 153° C., is obtained from isonitrosoacetone, $HON{:}CH.CO.CH_3$, on reduction, as the intermediate aminoacetone, $NH_2.CH_2.CO.CH_3$ (two molecules) then loses water and hydrogen to form the cyclic compound. Pyrazines can also be made by the con-



IV

densation of 1,2-diamines with 1,2-diketones.

Important derivatives of pyrazine include: hexahydropyrazine, or piperazine; the diketopiperazines or amino-acid anhydrides of general structure V, which are obtained by the elimination of alcohol from the esters of α-amino acids; and the various groups of azine dyes (*see* Dyes, Synthetic). (G. W. Wd.)



V

PYRAZOLES, in organic chemistry a series of compounds containing a five-membered ring with three carbon atoms united to two adjacent nitrogen atoms arranged as in formula I, which represents the structure of pyrazole itself.

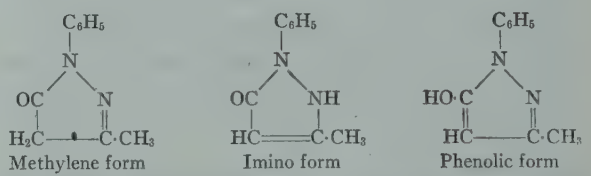
I II

The application in medicine of such pyrazole derivatives as antipyrine (*q.v.*) and pyramidone, and the production of synthetic dyes (*see* Dyes, Synthetic) of the pyrazolone type, lends a special interest to this chapter of organic chemistry.

The simplest synthesis of pyrazole is effected by heating together acetylene and diazomethane (H. von Pechmann, 1897), this process corresponding with the synthesis of pyrrole (*q.v.*) from acetylene and ammonia. The earliest synthesis of pyrazole was accomplished in 1889 by E. Buchner, who condensed ethyl diazoacetate with diethyl acetylenedicarboxylate, thus obtaining triethylpyrazole-3:4:5-tricarboxylate. The free pyrazoletricarboxylic acid on prolonged heating lost carbon dioxide and yielded pyrazole, which crystallizes in colourless needles melting at 70° C. (boiling point, 185° C.), and giving well-defined salts with acids. Pyrazole has certain chemical properties in common with pyridine and benzene; it exhibits an aromatic character and can be sulphonated or nitrated. Its 4-nitro-compound can be reduced to 4-aminopyrazole, which resembles the aromatic bases; it gives a colour reaction with bleaching powder solution and its hydrochloride is readily diazotized. Pyrazole-4-diazonium chloride couples with phenols and naphthols to form azo dyes after the manner of benzenoid diazo compounds.

Pyrazoline or 4:5-dihydropyrazole, formula II, is formed from acrolein and hydrazine hydrate and has also been obtained by the interaction of diazomethane and ethylene. It is a colourless liquid boiling at 144° C. The pyrazolines are unstable oxidizable substances resembling dihydrobenzene and its homologues; they are generally prepared by reducing the corresponding pyrazoles with sodium in alcoholic solution. On further reduction they yield pyrazolidines or tetrahydropyrazoles and when oxidized they develop blue or red colorations. This reaction, described by L. Knorr as the "pyrazoline reaction," is used for the detection of pyrazole and pyrazoline bases derived from phenylhydrazine.

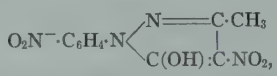
The pyrazolones (ketodihydropyrazoles), first prepared by Knorr in 1883, result from the elimination of the elements of alcohol from the hydrazones of β-ketonic acids. The most important member of this group is 1-phenyl-3-methyl-5-pyrazolone, the parent substance of antipyrine and an intermediate in the manufacture of certain pyrazolone dyes (eriochrome red, etc.). 1-Phenyl-3-methyl-5-pyrazolone, prepared by condensing together phenylhydrazine and ethyl acetoacetate, crystallizes in colourless prisms melting at 127° C. and although it is only known in this form, nevertheless it exhibits tautomerism (*see* Isomerism) and behaves as if it had one or another of the three following structures



Methylene form Imino form Phenolic form

When condensed with aldehydes, water is eliminated between aldehydic oxygen and the two hydrogens of the methylene group, thus indicating the methylene form. When methylated with methyl iodide in methyl alcohol to form the hydriodide of antipyrine (1-phenyl-2:3-dimethylisopyrazolone), the pyrazolone reacts in its imino form, the methyl group replacing the hydrogen of the imino group. Antipyrine (*q.v.*) and its therapeutically important derivatives and analogues are all constituted on the imino type. When in the production of synthetic dyes the pyrazolone is coupled with diazonium salts, it reacts in its third phenolic form, the diazo group replacing the hydrogen of the CH residue adjacent to the hydroxyl group.

Picrolonic acid,



or 4-nitro-1-p-nitrophenyl-3-methyl-5-hydroxypyrazole, is also a pyrazolone of phenolic type. Picrolonic acid closely resembles picric acid and is used to identify alkaloids and other bases owing to the formation of very sparingly soluble picrolonates.

PYRENE, an aromatic hydrocarbon found with chrysene (*q.v.*) in the coal-tar distillate boiling above 360° C. and also in "Stupp" fat, a by-product from the working up of mercury ores in Idria. It was long considered to be yellow but is now known to be colourless when pure. It melts at 156° C. and boils above 360° C. Chromic acid oxidizes it successively to pyrene-quinone and pyrenic acid; permanganate oxidizes the latter substance to naphthalene-1:4:5:8-tetracarboxylic acid, which confirms the structure I ascribed to pyrene, $C_{16}H_{10}$.

I II

1,2-Benzopyrene, II, occurs in coal tar to the extent of at least 0.003% and is of interest in that it is apparently the factor mainly responsible for the carcinogenic activity of the tar (*see* Carcinogenic Hydrocarbons).

BIBLIOGRAPHY.—A. E. Everest, *The Higher Coal-Tar Hydrocarbons* (1927); L. F. Fieser, *The Chemistry of Natural Products Related to Phenanthrene* (1936). (G. W. WD.)

PYRENEES, a range of mountains in southwest Europe (Span. *Pirinéos*, Fr. *Pyrénées*), separating the Iberian peninsula from France, and extending for about 240 mi., from the Bay of Biscay to Cape Creus, or, if only the main crest of the range be considered, to Cape Cerbère, on the Mediterranean sea. The main crest constitutes the Franco-Spanish frontier; except in the case of the valley of Aran, which belongs orographically to France but politically to Spain. The Pyrenees are conventionally divided into three sections, the central, the Atlantic or western and the Mediterranean or eastern. The central Pyrenees extend eastward from Canfranc to the valley of Aran, and include the highest summits of the whole chain, Aneto or Pic de Néthou (11,168 ft.) in the Maladetta ridge, Posets (11,047 ft.) and Mont Perdu or Monte Perdido (10,997 ft.). In the Atlantic Pyrenees the average altitude gradually diminishes westward; while in the eastern Pyrenees, except for one break at the eastern end of the Pyrénées Ariégeoises, the mean elevation is maintained, till a rather sudden decline occurs in the extreme eastern portion, the Albères. This threefold division is only valid so far as the elevation of the Pyrenean chain is concerned, and does not represent its geological structure or general configuration. The southern versant of the mountains is the more important. It is recognized that the range must be regarded as an elevated part of the earth's crust, the culminating portion of which is composed of a series of chains which do not coincide with the watershed, but cross it obliquely. Maps by Schrader and de Margerie (*Ann. du Club Alpin français,* 1891 and 1892) show the orderly arrangement of these chains. The primitive formations of the range are shown to be almost all continued diagonally on the Spanish side, and the central ridge thus presents the appearance of a series of wrinkles with an inclination (from northwest to southeast) greater than that of the chain as a whole. Other less pronounced wrinkles run from southwest to northeast and intersect the former series at certain points, so that it is by alternate digressions from one to the other series that the irregular crest of the Pyrenees acquires its general direction. Far from having impressed its own direction on the orientation of the chain at large, this crest is merely the resultant of secondary agencies by which the primitive mass has been eroded and lessened in bulk, and though its importance from a hydrographic point of view is still considerable, its geological significance is practically nil.

Geology.—The Pyrenees are divided into a number of longitudinal zones. The central zone (central Massifs) consists of Primary rocks, Archaean, Cambrian, Ordovician, Silurian, Devonian and Lower Carboniferous (Dinantian) together with great masses of granite. It forms most of the higher summits, but west of the Pic d'Anie it disappears beneath an unconformable covering of Cretaceous deposits. On the French side the central zone is followed by: (1) the zone of Ariège, consisting of Lower Cretaceous and Jurassic beds, together with granitic masses; (2) the zone of the Petites Pyrénées, Upper Cretaceous and Eocene; a thin outcrop of Jurassic and (3) the zone of Aragon, Eocene, and Primary rocks. On the Spanish side, from north to south, are: (1) the zone of Mont Perdu, Upper Cretaceous and Eocene with a thin outcrop of Jurassic; (2) the zone of Aragon, Eocene and (3) the zone of the Sierras, Trias, Cretaceous and Eocene. Although the number of zones is the same on the two flanks, they do not correspond. The zone of the Corbières has no equivalent in Spain, while in France there is no definite zone of Eocene like that of Aragon. The zone of the Petites Pyrénées, however, is clearly homologous with that of the Sierras. On the northern side granitic masses occur in the zone of Ariège among the Jurassic and Lower Cretaceous beds. On the southern side they are not found except in the axial zone, and the Jurassic and Lower Cretaceous deposits are reduced to a narrow band. In spite of these differences between the two flanks, the structure is to some extent symmetrical.

The tectonics of the Pyrenees are still only imperfectly understood. Some authorities consider the structure to be that of a fan, while others have shown that the phenomena of *recouvrement* play an important part there. Large masses of rock have been brought forward upon thrust planes over the edges of other beds with which they originally had no connection. Several cases have been described, but denudation has been carried further than in the Alps, and accordingly the masses overlying the thrust planes have been more completely removed.

The Pyrenean axis was outlined by the Hercynian movement and folding took place along it at the close of the Dinantian epoch and again before the Permian. Later the chain was completely submerged until early Cretaceous times, when the earth movements which raised the present mountains commenced and continued into the Oligocene period. The uplift of the Pyrenees was therefore completed before that of the Alps.

The arrangement of the Pyrenees in chains gently inclined near the centre but longitudinal everywhere else, is illustrated by the courses of the streams which flow down toward Spain. On the French side most of the longitudinal valleys have disappeared, except at the eastern end. On the south the principal streams, after cutting their way through the highest zone at right angles to the general direction of the range, become involved halfway to the plains in great longitudinal folds, from which they make their escape only after traversing long distances.

The total area of the Pyrenees is estimated at 21,044 sq.mi., two-thirds of which is on the southern versant. The mean elevation is placed at 3,930 ft., while the highest summit Pic de Néthou, is 11,168 ft. above sea level. The passes show a greater altitude than those of the Alps.

Gaves.—Four features of Pyrenean scenery are the absence of great lakes, as in the Alps; the rarity and great elevation of passes; the large number of the mountain torrents locally called *gaves,* which often form lofty waterfalls, surpassed in Europe only by those of Scandinavia; and the frequency with which the upper end of a valley assumes the form of a cirque. The highest waterfall is that of Gavarnie (1,385 ft.), at the head of the Gave de Pau; the Cirque de Gavarnie, in the same valley, is perhaps the most famous example of the cirque formation. Low passes only occur at the two extremities of the range, where the principal highroads and railways run between France and Spain; a third railway (Pau to Jaca via the pass of Somport) was opened in 1928. In the mountains themselves there are only five passes practicable for motors—the Col de la Perche, Col du Pourtalet, Col de Somport, Roncevalles road and the road through the Baztan valley.

Projects for further railway construction, including the building of tunnels on a vast scale, have been approved by the French and Spanish governments.

The metallic ores of the Pyrenees are not important. There are considerable iron mines at Vicdessos in Ariège and at the foot of Canigou in Pyrénées-Orientales. Coal deposits capable of being profitably worked are situated chiefly on the Spanish slopes and the French side has numerous beds of lignite. Mineral springs are abundant and specially noteworthy are the hot springs. The latter, among which those of Bagnères de Luchon and Eaux-Chaudes may be mentioned, are sulphurous and mostly situated high, near the margin of the granite. The lower springs, such as those of Bagnères de Bigorre (Hautes-Pyrénées,), Rennes (Aude) and Campagne (Aude), are mostly selenitic and not very warm. The use of hydroelectric power has been developed in recent years.

The amount of the precipitation, including rain and snow, is much greater in the western than in the eastern Pyrenees, causing a marked contrast between these sections of the chain in more than one respect. In the first place, the eastern Pyrenees are without glaciers, the quantity of snow falling there being insufficient. The glaciers are confined to the northern slopes of the central Pyrenees, and do not descend far down in the valleys, but have their greatest length in the direction of the chain. They form, in fact, a narrow zone near the crest of the highest mountains. There, as elsewhere in Europe, there are evidences of a much wider extension of the glaciers during the Ice Age. The best known glacier is that in the valley of Argelès. The snow line varies in different parts of the Pyrenees from 8,800 to 9,200 ft. above sea level.

A more marked effect of the high rainfall in the west is seen in the vegetation. The lower mountains in the extreme west are very well wooded, but the extent of forest declines eastward, and the eastern Pyrenees are peculiarly wild and naked, more so because there the granite massifs occur. There is a change, moreover, in the type of flora in passing from west to east. In the west the flora, at least in the north, resembles that of central Europe, while in the east it is distinctly Mediterranean in character. The Pyrenees are relatively as rich in endemic species as the Alps, and among the most remarkable instances of this is the occurrence of the sole European species of *Dioscorea* (yam), the *D. pyrenaica,* on a single high station in the central Pyrenees, and that of the monotypic genus *Xatardia,* only on a high pass between the Val d'Eynes and Catalonia. The genus most abundantly represented in the range is that of the saxifrages, several species of which are there endemic.

In their fauna also the Pyrenees present some striking instances of endemism. There is a distinct species of ibex (*Capra pyrenaica*) confined to the range, while the Pyrenean desman or water mole (*Mygale pyrenaica*) is found only in some of the streams of the northern slopes of these mountains, the only other member of this genus being confined to the rivers of southern Russia. Among the other peculiarities of the Pyrenean fauna are blind insects in the caverns of Ariège, the principal genera of which are *Anophthalmus* and *Adelops.*

The ethnology, folklore, institutions and history of the Pyrenean region form an interesting study: *see* ANDORRA; ARAGON; BASQUE PROVINCES; BEARN; CATALONIA; NAVARRE.

PYRÉNÉES-ORIENTALES, a department of southwestern France, bordering on the Mediterranean and the Spanish frontier, formed in 1790 of the old province of Roussillon and of small portions of Languedoc. Population (1946) 228,776, including many Spaniards. Area, 1,600 sq.mi. The department is bounded north by Ariège and Aude, east by the Mediterranean, south by Catalonia and west by the republic of Andorra. Its borders are marked by mountain peaks, on the north by the Corbières, on the northwest and southwest by the eastern Pyrenees, on the extreme southeast by the Albères, which end in the sea at Cape Cerbera. The coast is low-lying, with large lagoons. In the lowlands the climate is Mediterranean, with mild winters, dry summers and short and sudden rainstorms. Amélie-les-Bains is much frequented on account of its mild climate and sheltered position. The temperature ranges from 85° to 95° F. in summer, and in winter only occasionally falls as low as 26° or 27° F. The mean rainfall is 27 in. on the coast, but increases toward the hills. The most common wind is the *tramontane* from the north-northwest, as violent as the mistral of Provence and extremely parching. The *marinada* blows from the south-southeast.

On the Canigou massif to an altitude of 1,400 ft. are found the orange, the aloe, the oleander, the pomegranate and the olive; the vine grows to an altitude of 1,800 ft.; next come the chestnut (2,625 ft.), the rhododendron (from 4,330 to 8,330 ft.), pine (6,400) and birch (6,560); while stunted junipers grow to the summit. The cultivated land in Pyrénées-Orientales is devoted to winegrowing, market-gardening and fruit culture, the production of cereals being comparatively unimportant. The main source of wealth to the department is its wine, of which some kinds are strongly alcoholic and others are in request as liqueur wines (Rivesaltes, Banyuls). Early vegetables are grown in the irrigated lowlands, and fruit-growing is chiefly carried on in the river valleys. In iron Pyrénées-Orientales is one of the richest departments in France, the greater part of the ore being transported to the interior. Lignite and various kinds of stone are worked. The mineral waters are popular. Amélie-les-Bains has hot springs, chalybeate or sulphurous. In the arrondissement of Céret there are also the establishments of La-Preste-les-Bains, near Prats de Mollo, with hot sulphurous springs, and of Le Boulou, the Vichy of the Pyrenees. Near Prades are the hot sulphurous springs of Molitg, and a little north of Mont Canigou are the hot springs of Vernet, containing sodium and sulphur. In the valley of the Tet the sulphurous and alkaline springs of Thuès reach a temperature of 172° F. The baths of Les Escaldas, near Montlouis, are hot, sulphurous and alkaline.

The chief route (Southern railway) across the Pyrenees is from Perpignan through Montlouis, a fortified place, to Puigcerda in the Spanish province of Gerona, through the pass of La Perche, skirting in the French department an enclave of Spanish territory. Three other roads run from Perpignan to Figueras through the passes of Perthus (defended by the fort of Bellegarde), Banyuls and Balistres, the last-named being traversed by a railway. The chief towns of the three arrondissements are Perpignan, Céret and Prades: there are 18 cantons and 233 communes.

The department constitutes the diocese of Perpignan under the archbishop of Albi, and is attached to the appeal court and the *académie* (educational division) of Montpellier and to the region of the 16th army corps.

Perpignan, the capital town and a fortress of the first class, Amélie-les-Bains and Elne (*qq.v.*) are the chief towns.

Rivesaltes ([1946] 5,239) is the most populous town after Perpignan (74,984).

PYRETHRUM. The pyrethrum (family Compositae), regarded as a section of the genus *Chrysanthemum,* flowers in the early summer months, and is remarkable for the great variety of colour which it presents.

The type form is the Caucasian species *C. coccineum,* a hardy perennial, with finely cut leaves and large flower heads, having a ray of deep rose-coloured ligulate florets surrounding the yellow centre or disk. They bloom during the months of May and June, as well as later, and are always most welcome ornaments for the flower borders, and useful for cutting for decorative purposes.

The powdered flower heads of *C. coccineum* and *C. anethifolium* are the source of Persian insect powder, and *C. cinerariaefolium* yields Dalmatian insect powder. Both are important insecticide ingredients, commonly called pyrethrum.

PYRGI, an ancient town of Etruria, Italy, on the southwest coast, 9 mi. W.N.W. of Caere. The name is Greek (*πύργοι*, towers), and the place of considerable antiquity. Remains of its defensive walls exist in polygonal blocks of limestone and sandstone, neatly jointed. They enclosed a rectangular area about 200 yd. in width and at least 220 yd. in length, and there was a small harbour.

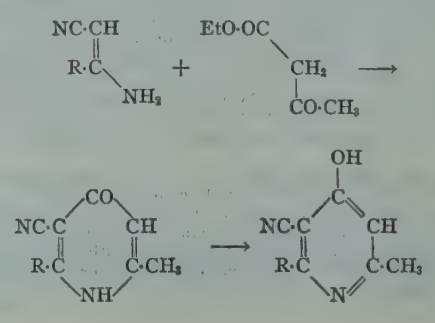
A rich temple of Leucothea there was plundered by Dionysius in 384 B.C. Later it became dependent on Caere, though it was not originally its harbour, for Alsium (*q.v.*) is a good deal nearer (5 mi. S.). The Romans planted a colony there about 200 B.C.

PYRGOS, a town of Greece, in the province of Elis and Achaea, 43 mi. S.S.W. of Patras. It is connected with its harbour, Katakolon, 7½ mi. distant, with Patras, Olympia and Kalamata (Kalámai), by rail. It has frequently been damaged by earthquakes. Pop. 22,500. Axis troops occupied it during World War II.

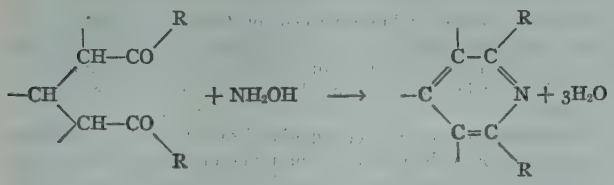
PYRIDINE is an organic compound of formula C_5H_5N. It belongs to the class of heterocyclic aromatic bases and is one of the most fully investigated members of that class. The pyridine nucleus does not occur so frequently in natural products as the condensed systems, quinoline (*q.v.*) and isoquinoline, derived from it, though it forms part of the alkaloid nicotine and of two of the known vitamins. Pyridine itself is formed in the destructive distillation of a variety of nitrogenous organic substances such as bones, coal and shale. It was first discovered by T. Anderson in his investigation (1845–51) of the oil produced in the distillation of bones, in which it occurs together with some of its homologues, notably the picolines (methylpyridines) and lutidines (dimethylpyridines). It is formed by this process only if the bones still contain unsaponified fat, since its formation is the result of interaction between acrolein formed from the glycerol of the fat and ammonia from the nitrogenous constituents. A large number of syntheses of the pyridine nucleus are known, which, though of no value for preparing pyridine itself, are used for obtaining its derivatives. Examples are:

1. Arthur Hantzsch's synthesis gives excellent yields and can be used in a variety of ways. Two molecules of a β-diketone or ketonic ester combine with one of an aldehyde and one of ammonia to give a dihydropyridine, easily oxidized to a pyridine derivative. Thus, collidine (2,4,6-trimethylpyridine) is obtained from acetoacetic ester, acetaldehyde and ammonia, the product being oxidized with nitrous fumes and the carboxyl groups eliminated by hydrolysis and heating with lime. The reaction involves the primary formation of an alkylidene-ketonic ester from one molecule of the ketonic ester and the aldehyde and of a β-amino crotonic ester from the other molecule of the ester and ammonia. It is sometimes convenient to prepare these two compounds separately and allow them to condense to the dihydropyridine.

2. A somewhat similar method (E. von Meyer) is the condensation of a β-ketonic ester with a "dinitrile," which has the structure $H_2N.CR:CH.CN$ and is formed from acetonitrile and the nitrile RCN. This leads to 4-hydroxypyridines.



3. 1, 5-diketones are converted into pyridines by hydroxylamine.



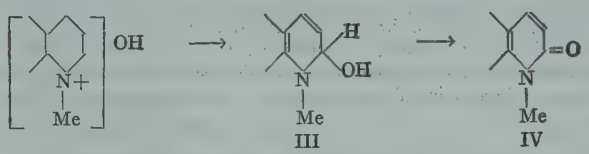
Pyridine itself is obtained commercially from bone oil. Since it is basic, it is removed from the low-boiling fraction of the oil by shaking with dilute sulphuric acid. Addition of excess sodium hydroxide gives a liquid layer consisting of pyridine and its homologues which are separated by fractional distillation. Pyridine is a stable, colourless liquid melting at −42° C. and boiling at 115.3° C. and with a characteristic and unpleasant smell. It is hygroscopic and completely miscible with water but insoluble in concentrated solutions of salts and alkali hydroxides. The higher homologues are progressively less soluble in water. Pyridine is an extremely valuable solvent, dissolving nearly all classes of organic compounds and also many inorganic salts. It is a tertiary amine and behaves as a monoacidic base; it is much weaker in this respect than ammonia, with an apparent dissociation constant of 2.3×10^{-9}; but it forms fairly stable salts, all of which are soluble in water except the mercurichloride, the chloroplatinate and the chloroaurate. Like ammonia it combines with some metals, especially those in the transitional groups of the periodic table, to give stable co-ordination compounds, and the study of these pyridine complexes has been of importance in the development of the theory of co-ordination and of the stereochemistry of the metals.

The pyridine nucleus in pyridine and its derivatives is extremely stable and shows a strong chemical resemblance to that of benzene. Its resistance to oxidation is, indeed, greater than that of the benzene nucleus since phenylpyridines are oxidized to pyridine carboxylic acids with destruction of the benzene nucleus. It was realized early that this similarity in behaviour meant similarity in structure, and W. Körner in 1869 and J. Dewar in 1871 independently put forward a formula (I) analogous to F. A. Kekulé's formula for benzene. This accounts for the known number of isomers in pyridine substitution products. The position of substituents is indicated either by the prefixes N, α, β and γ, or by numbers as in II; of the two systems the latter is to be preferred.

I II

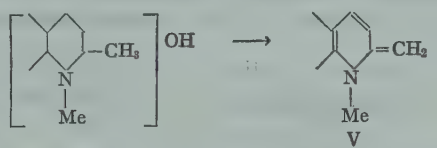
Formula I does not, however, express adequately the modern view of the structure of an aromatic compound. This is known to be a resonance hybrid of a number of states which differ in their electronic distribution. In pyridine there are the same possibilities of such states as in benzene and, although the evidence for resonance based on bond-length, heat of hydrogenation, etc., is not available with pyridine as with benzene, the analogies between the two sets of compounds are so strong that there can be no doubt of the similarity of their structures. Direct substitution takes place far less readily in pyridine than in benzene and certain reactions such as that of C. Friedel and J. A. Crafts do not occur. This behaviour recalls that of nitrobenzene, with which pyridine shows many analogies, and it arises from a similar electronic shift in the two molecules. As with nitrobenzene halogen atoms and methyl groups in the 2 and 4 positions are reactive, the latter condensing easily with aldehydes in the presence of acids. These facts are utilized in several preparative methods in the pyridine series.

As a tertiary base pyridine and its homologues combine with alkyl halides and sulphates to give quaternary ammonium salts, such as the methiodide (1-methylpyridinium iodide), $[C_5H_5N.CH_3]I$, and the "methosulphate" $[C_5H_5N.CH_3]SO_3.OCH_3$. These are typical salts of strong bases; but when they are treated with alkali, they show a characteristic behaviour common to a large number of cyclic bases. The quaternary hydroxide first formed changes, partly or wholly, into a nonbasic form in which the hydroxyl group is no longer an anion. There are two possibilities. In many cases the hydroxyl becomes covalently linked to the 2- or 4-carbon atom to give a pseudobasic form (III). The structure of the latter is revealed by its ready oxidation to a ketone, α-pyridone (IV).



III IV

With homologues of pyridine with a methyl group in the 2 or 4 position the hydroxyl ion is eliminated with a proton from that methyl group to give an anhydro base (V). The anhydro bases are of theoretical importance in the mechanism of the reactivity of these methyl groups.



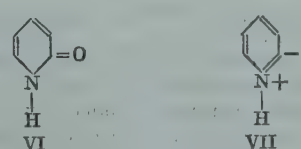
V

Of the derivatives of pyridine the carboxylic acids are of chief interest. They are often formed in the vigorous oxidation of alkaloids and other compounds derived from quinoline (*q.v.*) and isoquinoline and the elucidation of their structure was an important stage in establishing the constitution of these compounds. The monocarboxylic acids are both basic and acidic, but the dicarboxylic and polycarboxylic acids show no basic properties. In physical properties they resemble the aliphatic amino acids, having comparatively high melting points and being insoluble in ether and benzene; they should be regarded as internal salts. Examples of these acids are given in the table:

		Melting point °C.	Oxidation product of:
Picolinic acid	Pyridine-2-carboxylic acid	137	
Nicotinic acid	Pyridine-3-carboxylic acid	229	Nicotine and berberine
Quinolinic acid	Pyridine-2, 3-dicarboxylic acid	231	Quinoline
Cinchomeronic acid	Pyridine-3, 4-dicarboxylic acid	259	Quinine, cinchonine and isoquinoline

Nicotinic acid and its amide are of special interest in that they constitute the factor which is a member of the vitamin-B complex and prevents the deficiency disease pellagra in man. Another vitamin derived from pyridine is vitamin B_6 (adermin, pyridoxine) which is 2-methyl-3-hydroxy-4,5-di(hydroxymethyl)-pyridine.

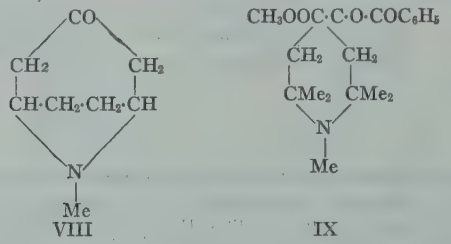
Amino- and hydroxypyridines with the substituent in the 2 or 4 position differ markedly from the 3 derivatives which resemble the corresponding benzene compounds; *e.g.*, 3-aminopyridine forms typical aromatic diazonium salts and the hydroxy compound is a true phenol. The properties of the 2 and 4 derivatives suggest that new structures such as VI and VII, of which the former is impossible in the 3 series, enter into the hybrid structure of the molecule.



VI VII

Piperidine, $C_5H_{10}N$, contains a saturated ring of five $-CH_2-$ groups and one $-NH-$ and is formed when pyridine is reduced catalytically or with sodium and alcohol. It occurs in nature in

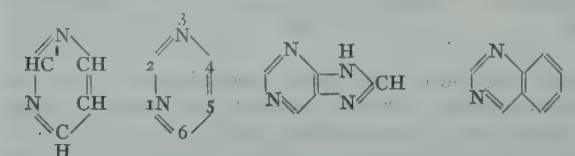
combination with piperic acid as piperine, the alkaloid of various peppers, and in coniine, the poisonous principle of hemlock, which is 2-*n*-propylpiperidine. It is a colourless liquid boiling at 106° C., miscible with water and most organic solvents and possessing a powerful ammoniacal smell. It is a much stronger base than pyridine or ammonia (dissociation constant, 1.6×10^{-3} at 25° C.) and in chemical properties behaves as a typical aliphatic secondary amine. The NH group can be readily acylated and alkylated and it gives an N-nitroso compound with nitrous acid. Exhaustive methylation leads to piperylene, 1,3 pentadiene, the double bonds rearranging to the conjugated position during the decomposition. Piperidine is of value as an alkaline catalyst in several organic condensations and was one of the earliest substances to be used as an accelerator in rubber vulcanization. Of its derivatives, the ketones with the $-CH_2-$ group in the 4 position oxidized to $-CO-$ are of interest. Compounds of this type are formed by the action of ammonia on the self-condensation products of acetone, such as phorone and mesityloxide. Their structure recalls that of tropinone (VIII), a ketone obtained by oxidizing tropine, a secondary alcohol which is the cleavage product of the alkaloids atropine and hyoscyamine, and is of the same fundamental structure as cocaine, a valuable local anaesthetic.



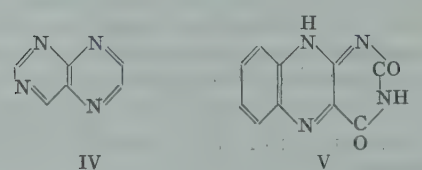
VIII IX

On this analogy a series of synthetic anaesthetics has been prepared from the 4-piperidones derived from acetone; an example is eucaine (IX). (T. W. J. T.)

PYRIMIDINES, Metadiazines or 1,3-Diazines, a group of nitrogenous organic compounds of outstanding biochemical interest, since many derivatives of pyrimidine (I) and of the condensed systems purine (II), quinazoline (III), pteridine (IV), isoalloxazine (V), containing the six-membered heterocyclic nucleus of pyrimidine, are important constituents of living organisms. Among such compounds are the pyrimidines, orotic acid and vitamin B_1; the purines, uric acid, the adenine group and the caffeine alkaloids; the quinazoline alkaloid, vasicine; the pteridines, xanthopterin and the folic acid vitamins; and the isoalloxazine, riboflavin.



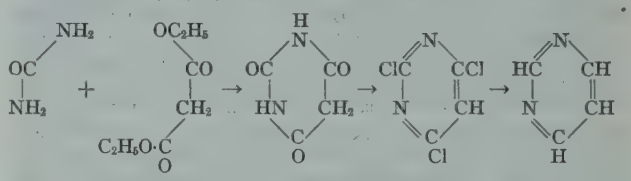
I II III



IV V

The classical researches of F. Wöhler and J. von Liebig on the structure of uric acid, which had been isolated from urinary calculi by K. W. Scheele in 1776, led to the formula proposed by L. Medicus in 1885 and to the study of a series of related naturally occurring compounds designated "purines" by E. Fischer in 1899. Of these, the adenine group including adenine, guanine, cytosine, uracil and thymine are of major interest since they occur as polymeric phosphorylated ribosides and desoxyribosides in the nucleic acids. Adenine is also a constituent of the coenzyme derived from the B-complex vitamins and of adenosine triphosphate. This occurrence of pyrimidines and purines in nucleic acids, in coenzymes and in other cell constituents, and the concept that desoxyribonucleic acids are associated with genes in the determination of inherited traits of organisms, stimulated and intensified interest in the biochemical study of these series of compounds.

Knowledge of the synthetic methods by which the pyrimidine nucleus can be built up and of the numerous transformations of the substituent groups was amassed from these biochemical investigations. The most useful and commonly used type of synthesis is that in which the nitrogenous component such as urea, guanidine or one of the amidines is condensed with a compound such as ethyl malonate or a suitable diketone. This ring formation and subsequent modification of the substituent groups is illustrated in the synthesis of pyrimidine (I) itself by condensation of urea with ethyl malonate and conversion of the resulting barbituric acid (VI) by chlorination and reduction.



VI I

Pyrimidine, a stable crystalline compound melting at 20–22° C. and boiling at 124° C. is readily soluble in water.

Considerable advance has been made toward an understanding of the biosynthesis of the nucleic acids and of its inhibition. The role of the B vitamins in purine and pyrimidine biosynthesis and that of the purine and pyrimidine antimetabolites in nucleic acid metabolism were reviewed by W. Shive and L. D. Wright in *Vitamins and Hormones.*

Considering the importance of pyrimidines in cellular metabolism it is not remarkable that they have pharmacological importance. Barbituric acid derivatives in which the two hydrogen atoms at the 5 position are replaced by alkyl groups of varying complexity are hypnotic, sedative and even anaesthetic in their action. A pyrimidine substituted sulfonamide, sulfadiazine, is widely used in the treatment of bacterial infections. (C. R. Al.)

Soc.*, 33:978–85 (1911 *et seq.*); B. Lythgoe, *Quart. Revs.*, vol. iii, pp. 181–207 (London, 1949); R. Harris and K. Thimann (eds.), *Vitamins and Hormones,* vol. ix, pp. 75–130, 130–159 (1951).

PYRITE or Pyrites, a term applied to iron disulphide when crystallized in the cubic system. The original word "pyrites" (from Gr. πῦρ, fire) had reference to the fact that sparks might be elicited on striking the mineral violently, as with flint, so that πυρίτης λίθος meant a stone which struck fire. Hence the name seems to have been applied also to flint and perhaps to emery and other hard stones. Nodules of pyrite have been found in prehistoric barrows and elsewhere under conditions suggesting their use as a primitive means of producing fire. Even in late historic time it was employed in some old wheel-lock guns. The compound FeS_2 is dimorphous, and the practice is to distinguish the cubic form as pyrite and the orthorhombic as marcasite (*q.v.*).

Iron pyrites, or pyrite, belongs crystallographically to the parallel-faced hemihedral class of the cubic system. Its common forms are the cube, the octahedron and the pentagonal dodecahedron, or various combinations of them. It has a conchoidal fracture and a very indistinct cubic cleavage. Its hardness is about 6, and its specific gravity 4.9 to 5.2, being rather more than that of marcasite. Moreover, the colour of pyrite is brass-yellow, while that of marcasite when untarnished may be almost tin-white. From copper pyrites (chalcopyrite) pyrite is distinguished by its superior hardness and by its paler colour. On exposure to meteoric influences pyrite commonly becomes brown, by formation of ferric hydrate. Such a change is very common on the outcrop of mineral veins, forming what miners call "gozzan."

According to the formula FeS_2, pyrite contains theoretically 46.67% of iron and 53.33% of sulphur. Practically, however, it frequently contains other metals, such as copper, cobalt and nickel. Gold is often present, and in many gold-mining districts the precious metal is obtained mainly from auriferous pyrite. As pyrite, from its brass-yellow colour, is sometimes mistaken for gold, it has been called "fool's gold." Traces of thallium, which are present in some pyrite, may be detected in the flues of the furnaces where the metal is roasted. Arsenic is an impurity which may be of serious consequence in some of the purposes to which pyrite is applied. The presence of copper, nickel and arsenic is possibly the result in many cases of traces of kindred minerals, such as chalcopyrite, pentlandite and mispickel.

Distribution and Uses.—Pyrite is a mineral of very wide distribution, occurring under varied conditions and probably originating in various ways. It is common in mineral veins, usually associated with quartz, and is often known to miners as mundic. It occurs crystallized, commonly in cubes, in schistose and slaty rocks, and less abundantly in the younger sedimentary deposits. In coal it not infrequently forms bands and nodules known as brasses, and may also be finely disseminated through the coal as black pyrites; but much of the so-called pyrite of coal is really marcasite. Films of pyrite sometimes coat the joint planes of coal. Pyritous shales have been largely used in the manufacture of alum, and are therefore known as alum shales. Many fossils are mineralized with pyrite, which has evidently been reduced by the action of decomposing organic matter on a solution of ferrous sulphate, or perhaps less directly on ferrous carbonate dissolved in water containing carbonic acid, in the presence of certain sulphates. A similar action probably explains the origin of pyrite and marcasite in coal and lignite, in clay and shales and in limestone like chalk.

Pyrite is largely worked for the sake of the sulphur that it contains, and has displaced sulphur in the manufacture of sulphuric acid. For this purpose its value depends on the proportion of sulphur present. Pyrite low in sulphur is incapable of sustaining its own combustion without the aid of an external source of heat, and 45% of sulphur is, for economic reasons, usually regarded as the lowest percentage admissible for sulphuric acid manufacture. It is also important for this purpose that the ore should be as free as possible from arsenic (*see* SULPHURIC ACID).

An extremely important variety of pyrite is that which is more or less cupriferous and is commonly known commercially as copper pyrites (*see* CHALCOPYRITE), though distinct mineralogically from that mineral. It consists, indeed, mainly of pyrite, with a notable but variable proportion of copper, sometimes with silver and gold, and not infrequently associated with lead and zinc sulphides. The copper probably exists as disseminated chalcopyrite. Deposits of such cupriferous pyrite are widely distributed and are often of great magnitude. They are generally of lenticular form, and usually occur in or near the contact of eruptive rocks with schists or slates; the presence of the igneous rock being probably connected genetically with their origin.

The world's annual production of iron pyrite is about 4,500,000 tons. The largest producer is Spain, with about 2,000,000 tons, including the cupriferous pyrite. France yields about 200,000 tons, largely from the Sain Bel mines, department of the Rhône. Then follows Portugal, with its important output of cupriferous pyrites. In the United States the production of pyrite reaches about 170,000 tons per annum. The state of Virginia is the chief producer, followed successively by Georgia, North Carolina, Colorado, Massachusetts, California, Missouri, New York, etc. From Indiana and Ohio a quantity of pyrite is obtained as a by-product in coal mining. The United Kingdom yields but little pyrite, the annual output being not more than about 5,000 tons. Large quantities of sulphur ore were, however, formerly worked in the Vale of Avoca, County Wicklow, Ire. Finely crystallized specimens of pyrite are obtained from many other localities, especially from Cornwall, Elba and Traversella, near Ivrea, in Piedmont.

PYRO AND PIEZO ELECTRICITY: *see* ELECTRICITY.

PYROGALLOL or PYROGALLIC ACID, a trihydroxybenzene, $1,2,3\text{-}C_6H_3(OH)_3$, first prepared by K. W. Scheele in 1786 by heating gallic acid. It is used as a photographic developer and also as an oxygen absorbent in gas analysis. It has antiseptic properties and is employed medicinally in the treatment of psoriasis. The process of manufacture is still based on Scheele's procedure. Gallic acid with half its weight of water is heated in an autoclave until the pressure reaches 12 atm. and the temperature registered is 175° C. Steam and carbon dioxide are then allowed to escape, leaving in sufficient water to keep the pyrogallol liquid. The cooled solution is decolorized with animal charcoal and evaporated down until the volatile pyrogallol has distilled over into flat iron receivers. The solidified material is purified by repeated distillation or sublimation. Pyrogallol crystallizes in colourless leaflets or needles, melts at 134° C. and is easily sublimed; it distils at 309° C. under the ordinary pressure with partial decomposition. It dissolves in $2\frac{1}{4}$ parts of water at 13° C., and its aqueous solution develops a blue colour with ferrous sulphate containing a little ferric salt. Its alkaline solution, when exposed to air, rapidly becomes black because of the absorption of oxygen with the production of complex coloured substances.

(G. T. M.)

PYROLUSITE, a mineral consisting essentially of manganese dioxide (MnO_2), of importance as an ore of manganese. It is a soft, black, amorphous mineral, often with a granular, fibrous or columnar structure and sometimes forming reniform crusts. It has a metallic lustre and a black or bluish-black streak, and readily soils the fingers. The specific gravity is about 4.8.

Supposed crystals of pyrolusite have been proved to be pseudomorphs after manganite; in fact, the mineral often results by the dehydration and oxidation of manganite ($Mn_2O_3.H_2O$), and for this reason it frequently contains a little water. True crystals of manganese dioxide are referred to the rare species polianite; they are tetragonal and isomorphous with cassiterite. Pyrolusite is an alteration product of other manganese minerals—manganite, rhodochrosite, rhodonite, etc. It occurs as irregular masses and nodules in the residual clayey materials resulting from the decomposition of various rocks; for example, limestone. That it is readily deposited from solution is shown by the frequent occurrence of black dendritic markings in the crevices of rocks, excellent examples of which are seen in mocha stone (*q.v.*) and in the lithographic stone of Solenhofen, Bavaria. It is deposited by some springs and manganiferous nodules are dredged from the floor of the deep sea.

As an ore, pyrolusite is extensively mined at Ilmenau and other places in Thuringia, in north Wales, at several places in the U.S. (Vermont, Virginia, Arkansas, etc.), Nova Scotia, Brazil, India, etc. Together with the rather less important ore, psilomelane, it has various economic applications; it is extensively used for the manufacture of spiegeleisen and ferromanganese, and of various alloys, such as manganese-bronze; as an oxidizing agent it is used in the preparation of chlorine and disinfectants (permanganates); and when mixed with molten glass it oxidizes the ferrous iron to ferric iron, and so discharges the green and brown tints, hence the name pyrolusite, from Gr. πῦρ (fire) and λύειν (to wash). As a colouring material, it is used in calico printing and dyeing; for imparting violet, amber and black colours to glass, pottery and bricks; and in the manufacture of green and violet paints.

PYROMETER, an instrument for measuring high temperatures (Gr. πῦρ, fire, μέτρον, a measure). The term was first used by P. van Musschenbroek to denote an instrument wherein the expansion of a metal rod measured the temperature. Discontinuous thermoscopes, depending on the fusion of a metal or salt, have also been employed.

Prinsep prepared a series of alloys of silver and gold and of gold and platinum whose melting points, as determined by accurate instruments, covered a range of temperature from 954° C. to 1,775° C., at intervals of from 25° C. to 30° C. By placing ingots in a furnace and observing which one melted a fair idea of the temperature was obtained. Carnelley and Williams employed certain salts of known melting point; however, the Seger's cones, employed in porcelain manufacture, depend on the softening of small cones made of clay. The instruments employed to-

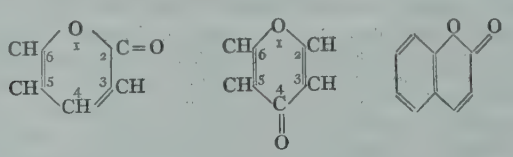
day depend either on electrical effects produced in wires inserted in the furnace and so raised to its temperature, or upon measurements made on the radiation emitted by the furnace. (*See* also THERMOMETRY for scientific forms.)

PYROMORPHITE, a mineral species composed of lead chlorophosphate $(PbCl)Pb_4(PO_4)_3$, sometimes occurring in sufficient abundance to be mined as an ore of lead.

Crystals are common, and have the form of a hexagonal prism terminated by the basal planes, often with a barrellike curvature, globular and reniform masses also being found. Between pyromorphite and the corresponding chloroarsenate (mimetite, *q.v.*) the resemblance in external characters is so close that, as a rule, it is possible to distinguish them only by chemical tests, and they were formerly confused under the names green lead ore and brown lead ore. The phosphate was first distinguished chemically in 1784, and it was named pyromorphite from Gr. πῦρ (fire) and μορφή (form), because when a fragment is fused the globule assumes a faceted form on solidifying. The colour is usually some bright shade of green, yellow or brown, and the lustre is resinous. The hardness is 3.5 and specific gravity 6.5–7.1. Pyromorphite has resulted from the alteration of galena in the oxidized portions of metalliferous veins, and is frequently met with in the upper levels of lead mines.

PYROMUCIC ACID (FUROIC ACID): *see* FURFURAL.

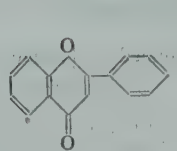
PYRONES, a term used in organic chemistry to describe a group of six-membered oxygen-containing heterocyclic compounds. Pyrones are of two main types, those derived from 1:2-pyrone (I) and those derived from 1:4-pyrone (II). The former may be regarded as cyclic esters (lactones) and the latter contain an extended ester group (O—CH=CH—CO). Like esters, they are hydrolyzed by alkali and show no ketonic properties. Pyrones possess stability similar to that of aromatic compounds; this is due to resonance (*cf.* benzene).



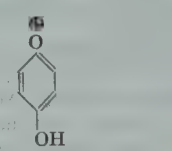
I

II

III



IV



V

1:2-Pyrone (coumalin), shown in diagram I, is a colourless liquid with a 5° C. m.p. and 120° C. b.p. at 30 mm. pressure. It is prepared by heating malic acid with concentrated sulphuric acid giving 1:2-pyrone-5-carboxylic acid (coumalic acid), and this yields 1:2-pyrone on decarboxylation. Alkaline hydrolysis of 1:2-pyrone gives crotonaldehyde. Compounds containing the 1:2-pyrone nucleus which occur naturally include phenylcoumalin (6-phenyl-1:2-pyrone) from cotobark and derivatives of coumarin (*q.v.*) (5:6-benz-1:2-pyrone), represented in diagram III.

1:4-Pyrones have been extensively investigated. 1:4-Pyrone itself forms colourless needles, m.p. 32.5° C., b.p. 215–217° C., and it may be prepared by heating chelidonic acid (*see* below) or comanic acid (1:4-pyrone-2-carboxylic acid), preferably in the presence of copper powder. A number of compounds of the 1:4-pyrone series are found in nature. For example, the leaves of the lily of the valley and the celandine (*Chelidonium majus*) contain chelidonic acid (1:4-pyrone-2:6-dicarboxylic acid). The structure of this acid was established by decarboxylation to give 1:4-pyrone and by alkaline cleavage, giving oxalic acid and acetone. Meconic acid (3-hydroxy-1:4-pyrone-2:6-dicarboxylic acid) is found in association with the opium alkaloids. Maltol (3-hydroxy-2-methyl-1:4-pyrone) is present in pine needles and larch bark; it is also formed when barley is roasted in the manufacture of malted beverages. Kojic acid (2-hydroxymethyl-5-hydroxy-1:4-pyrone) is formed during the growth of the fungus *Aspergillus flavus* on a medium containing glucose or xylose. Maltol and kojic acid show reactions characteristic of the phenols, thus demonstrating the aromatic character of the 1:4-pyrone nucleus; the acidic nature of kojic acid is caused by the hydroxyl group in position 5.

1:4-Pyrones may be synthesized by dehydration of 1:3:5–triketones. For example, 2:6-dimethyl-1:4-pyrone may be prepared by dehydration of diacetylacetone ($CH_3.CO.CH_2.CO.CH_2.CO.CH_3$). It is also formed by the reaction of concentrated hydrochloric acid with dehydracetic acid which is obtained from ethyl acetoacetate by treatment with sodium ethoxide. Chelidonic acid has been synthesized by condensing acetone with diethyl oxalate in the presence of sodium ethoxide. The intermediate ethyl acetone-dioxalate ($EtO_2C.CO.CH_2.CO.CH_2.CO.CO_2Et$), by dehydration and hydrolysis of the ester groups with concentrated hydrochloric acid, gave chelidonic acid.

The formation of pyridine derivatives from 1:4-pyrones is noteworthy in that it may be of biogenetic significance. For example, 2:6-dimethyl-1:4-pyrone, when treated with dimethyl sulphate and then with perchloric acid, gives a perchlorate which, with ammonium carbonate, yields 2:6-dimethyl-4-methoxypyridine. Similarly chelidonic acid, when heated with ammonia, gives chelidamic acid, and kojic acid, when methylated, treated with ammonia and then with phosphorus and hydriodic acid, gives 4:5-dihydroxy-2-methylpyridine. Another interesting property of pyrones is the formation of salts with acids. 2:6-Dimethylpyrone gives well-defined salts with hydrochloric, chloroplatinic and tartaric acids. The stability of these salts is associated with the resonance hybrid structure for the cation which is best represented by diagram V.

Many derivatives of 1:4-pyrones occur naturally; some have been used as dyes. They include chromones (5:6-benz-1:4-pyrones), flavones (2-phenyl-5:6-benz-1:4-pyrones; *see* diagram IV), isoflavones (3-phenyl-5:6-benz-1:4-pyrones) and xanthones (2:3-5:6-dibenz-1:4-pyrones; *see* article XANTHONE). (W. D. Os.)

PYROPHORIC ALLOYS, alloys which when filed or scratched give off bright sparks. Alloys containing about 15% iron and mixtures of rare-earth metals with small amounts of antimony, bismuth, copper and silicon are used in various lighters.

PYROPHORUS, a material which inflames spontaneously on contact with air. Homberg's pyrophorus (Gr. πῦρ, fire; φέρειν, to bear), one of the earliest known, was prepared by heating alum with finely divided carbon or organic material (lampblack, starch or flour) in a closed tube. The product, a mixture of potassium sulphide, aluminum sulphate and carbon, is spontaneously inflammable. The oxides of iron, cobalt or nickel when reduced by hydrogen at low red heat leave the metal in a state of such fine division that it becomes incandescent on exposure to air. Lead tartrate heated in a closed tube leaves a pyrophoric residue of finely divided lead. Liquid phosphine, P_2H_4, and organometallic compounds such as cacodyl, zinc diethyl, trimethylstibine, etc., are spontaneously inflammable liquids.

PYROPHYLLITE, a mineral species composed of hydrous aluminum silicate, $HAl(SiO_3)_2$. It occurs in two more or less distinct varieties, crystalline folia and compact masses; distinct crystals are not known.

The folia have a pronounced pearly lustre because of the presence of a perfect cleavage parallel to their surfaces; they are flexible but not elastic and are usually arranged radially in fanlike or spherical groups. This variety, when heated before the blowpipe, exfoliates and swells up to many times its original volume, hence the name pyrophyllite, from the Greek πῦρ (fire) and φύλλον (a leaf), given by R. Hermann in 1829. The colour of both varieties is white, pale green, grayish or yellowish; they are very soft (hardness = 1–2) and are greasy to the touch. The specific gravity is 2.8–2.9. The two varieties are thus very similar, respectively, to talc (*q.v.*) and its compact variety steatite, which is, however, a hydrous magnesium silicate. The compact variety of pyrophyllite is used for slate pencils and tailors' chalk ("french chalk") and is carved by the Chinese into small images and orna-

ments of various kinds. Other soft compact minerals (steatite and pinite) used for these Chinese carvings are included with pyrophyllite under the terms agalmatolite and pagodite.

Pyrophyllite occurs in schistose rocks, often associated with kyanite, of which it is an alteration product. Pale-green foliated masses, very like talc in appearance, are found at Beresovsk near Ekaterinburg in the Urals, and at Zermatt, Switz. The most extensive deposits are in the Deep river region of North Carolina, where the compact variety is mined, and in South Carolina and Georgia.

PYROTECHNY: *see* FIREWORKS.

PYROXENE, in mineralogy, an important group of rock-forming minerals very similar in chemical composition and general characters to the amphiboles (*q.v.*). The name (from Gr. πῦρ, fire, and ξένος, stranger) was originally given by R. J. Haüy in 1796 to the augite of the lavas of Vesuvius, in the belief that the crystals had been caught up by the lavas that contained them; but next to the feldspars the pyroxenes are the commonest constituents of igneous rocks, being especially characteristic of those of basic composition (basalt, gabbro, pyroxenite, etc.). Though crystallizing in three different systems, the pyroxenes all possess distinct prismatic cleavages, with an angle of about 87° between them. Usually the habit of these minerals is that of short prisms, but in the alkaline varieties long slender prisms are often characteristic; *e.g.*, acmite.

The pyroxenes are conveniently subdivided into three series according to the symmetry of their crystals. Chemically they are essentially metasilicates. The principal species are indicated in the accompanying table.

Rhombic Series

Enstatite	$MgSiO_3$
Bronzite	$(Mg, Fe)SiO_3$
Hypersthene	$(Fe, Mg)SiO_3$

Monoclinic Series

Clinoenstatite	$MgSiO_3$
Diopside	$CaMg(SiO_3)_2$
Hedenbergite	$Ca(Mg, Fe)(SiO_3)_2$
Enstatite Diopside or Magnesium Diopside	$m\text{-}(Mg,Fe)SiO_3.n\text{-}Ca(Mg,Fe)(SiO_3)_2$
Augite	$Ca(Mg,Fe)(SiO_3)_2$ with $(Mg,Fe)SiO_3$ and $(Al,Fe''')_2O_3$
Acmite	$NaFe'''(SiO_3)_2$
Jadeite	$NaAl(SiO_3)_2$
Spodumene	$LiAl(SiO_3)_2$
Wollastonite	$CaSiO_3$
Pectolite	$HNaCa_2(SiO_3)_3$
Rosenbuschite	$Na_2Ca_3[(Si,Zr,Ti)O_3]_4$

Triclinic Series

Rhodonite	$MnSiO_3$
Pyroxmangite	$(FeMn)SiO_3$
Bustamite	$(Ca,Mn)SiO_3$
Babingtonite	$Ca(Fe,Mn)(SiO_3)_2$ with Fe_2O_3 and SiO_2
Sobralite	$CaMgFe_2Mn_4(SiO_3)_8$
Hiortdahlite	$4Ca(Si, Zr)O_3.Na_2ZrO_2F_2$

Many of these species are described under their respective headings, to which reference should be made. Others not so treated are briefly mentioned below. Clinoenstatite, the monoclinic magnesium metasilicate, occurs in meteorites. It is the only stable metasilicate of magnesium prepared in the laboratory. It melts incongruently at 1,557° C. with separation of forsterite. Enstatite diopside or magnesium diopside is an isomorphous mixture of diopside with clinoenstatite, and as such is a characteristic pyroxene of the quartz-dolerite group of igneous rocks. Hedenbergite is a black or dark-green pyroxene characteristic of metasomatically metamorphosed limestones or skarns, and is often associated with andradite garnet. A fluorine-bearing diopside known as mansjöite occurs at Mansjö mountain in Sweden. The manganese- and zinc-bearing monoclinic pyroxenes include schefferite, $Ca(Mg,Fe,Mn)(SiO_3)_2$, and jeffersonite,

$$Ca(Mg,Fe,Mn,Zn),(SiO_3)_2,$$

both occurring at Franklin Furnace, N.J.

Jadeite is a white to gray pyroxene occurring in dense fibrous masses in association with serpentine, glaucophane schists or eclogites in Turkistan, Tibet, Burma and other places. It possesses a distinct ethnographic interest because of its use by prehistoric man in the manufacture of images and utensils. Pectolite occurs as a secondary mineral in the form of radiating fibrous crystals in druses and veins of basic igneous rocks of the triclinic series of minerals classified as pyroxenes; bustamite, fowlerite and pyroxmangite are closely related to rhodonite. The two former occur at Franklin Furnace. Sobralite occurs with manganese-garnet in an eulysite from Södermanland, Swed. According to the most recent analyses, babingtonite contains alkalies and water as essential constituents. The mineral occurs in black crystals on feldspar in the granite of Baveno, It., and also as a product of contact metamorphism in Japan and elsewhere. The rare zirconium-bearing silicates, hiortdahlite, and the monoclinic rosenbuschite occur in the nepheline-rich rocks of southern Norway and of the Los archipelago (Guinea). (C. E. T.)

PYROXENITE, a rock consisting essentially of minerals of the pyroxene group, such as augite and diallage, hypersthene, bronzite or enstatite. Names have been given to members of this group according to their component minerals; *e.g.*, pyroxenite (augite), diallagite (diallage), hypersthenite (hypersthene), bronzitite (bronzite) and websterite (diallage and hypersthene). Closely allied to this group are the hornblendites, consisting essentially of hornblende. The term perknite (Gr. περκνός, dark) has also been used to designate the whole series.

PYRRHO OF ELIS (*c.* 360–270 B.C.), a Greek sceptic philosopher and founder of the school known as Pyrrhonism. Diogenes Laërtius (ix, 61), quoting from Apollodorus, says that he was at first a painter, and that pictures by him were in existence in the gymnasium at Elis. Later he was diverted to philosophy by the works of Democritus. He studied in India under the gymnosophists (*q.v.*) and under the magi in Persia. Returning to Elis, he lived in poor circumstances, but highly honoured by the Elians and also by the Athenians, who gave him the rights of citizenship. His doctrines are known mainly through the satiric writings (Σίλλοι) of his pupil Timon of Phlius (the sillographer). The main principle of his thought is expressed in the word *acatalepsia*, which implies the impossibility of knowing things in their own nature. Pyrrho concludes that, since nothing can be known, the only proper attitude is imperturbability (*ataraxia*). The impossibility of knowledge, even in regard to our own ignorance or doubt, should induce the wise man to withdraw into himself, avoiding the stress and emotion which belong to the contest of vain imaginings. (*See* PHILOSOPHY, HISTORY OF.)

PYRRHOTITE, a mineral species consisting of iron sulphide and crystallizing in the hexagonal system. The formula is Fe_nS_{n+1}, in which n may vary from 5 to 16; such a composition being explained by the "solid solution" of sulphur in ferrous sulphide (troilite). Small amounts of nickel and cobalt are often present; the mineral is of some importance as an ore of gold, and the nickeliferous pyrrhotite of Sudbury, Ont., is by far the most important source of nickel.

Crystals have the form of hexagonal plates bounded at their edges by faces of a hexagonal prism and pyramids, which are deeply striated horizontally. More frequently, however, the mineral is massive, with a laminar or granular structure. It is magnetic, sometimes with polarity, and is therefore often called magnetic pyrites. The colour is bronze yellow, the lustre metallic and the streak grayish black. The hardness is 4 and the specific gravity 4.58–4.64.

Pyrrhotite occurs in metalliferous veins and as grains and plates disseminated through various rocks.

PYRRHUS (*c.* 318–272 B.C.), king of Epirus, son of Aeacides and a member of the royal family of the Molossians. He claimed descent from Pyrrhus, the son of Achilles, and was also connected with the royal family of Macedonia through Olympias, the mother of Alexander the Great. He became king when still a boy, and fought for Demetrius Poliorcetes at Ipsus in 301. He was sent to the court of Ptolemy as a hostage by Demetrius, married Ptolemy's stepdaughter Antigone, and became a thorn in Demetrius' side. For some time he occupied most of Macedonia under the terms of a truce, but in 286 Lysimachus defeated him at Edessa and drove him back into Epirus.

In 281 Tarentum, in southern Italy, asked his assistance against Rome. Pyrrhus went with about 25,000 men, and might, with more wholehearted assistance from the Greek cities, have been a fatal obstacle to the growth of Rome, faced with Etruscans and Gauls in the north as well as this reinforced opposition in the south. Greeks and Romans met at Heraclea, and Pyrrhus, with the advantage gained by his cavalry and elephants, completely defeated the consul M. Valerius Laevinus, but at the cost of very heavy losses. This battle is the origin of the phrase "a Pyrrhic victory." He advanced on Rome through Latium, but the towns were all garrisoned, and though the senate was inclined to agree to terms, the speech of Appius Claudius the censor decided them against it. Cineas, Pyrrhus' minister, was sent back with a refusal to negotiate as long as Pyrrhus' troops were in Italy.

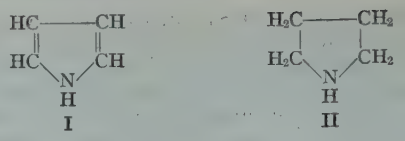
In 279 Pyrrhus won another victory at Asculum in Apulia. He then went to Sicily with the idea of driving the Carthaginians out; his military operations were successful, and Rome and Carthage united in an alliance against him, while his despotic methods alienated the Sicilian cities. He stayed three years in Sicily and then returned to Italy, but the Greek cities now entirely failed to support him and he was completely defeated at Beneventum in 275. He left Italy, saying, "what a battlefield I am leaving to Rome and Carthage"—a remark of some insight. The rest of his life was passed in wars at home, including a victory over Antigonus Gonatas, and an unsuccessful expedition into Sparta at the invitation of Cleonymus in 273. He was killed in 272 in a night skirmish in a street in Argos. Pyrrhus wrote a history of the art of war, which is praised by Cicero and quoted by Dionysius of Halicarnassus and Plutarch.

The chief ancient authority for the life of Pyrrhus is Plutarch; *see* also Polybius xviii, 11, and elsewhere; Dion. Halic. xviii, 1; xix, 6–9; Pausanias i, 13; Justin xviii, 1, 2; xxiii, 3; xxv, 4, 5. Modern monographs by G. F. Hertzberg, "Rom und König Pyrrhus" (popular; in O. Jäger, *Darstellungen aus der römischen Geschichte* [1870]); R. von Scala, *Der Pyrrhische Krieg* (1884), with map of Roman garrison system in 281; R. Schubert, *Geschichte des Pyrrhus* (1894), with full list of authorities; also ROME: *Ancient History*.

PYRROLE. A colourless oil whose existence in coal tar was surmised by the German chemist F. F. Runge in 1834 but which was first isolated and studied by the Scottish chemist Thomas Anderson in 1857. The name is derived from Greek and Latin roots meaning "fiery oil" from the fiery red colour imparted by pyrrole to a wood splint previously moistened with acid. Pyrrole is of great historical interest because of the fact that one of its derivatives, indole (*q.v.*), is the fundamental building block of the regal dye of the ancients, Tyrian purple, as well as of the most important ancient and mediaeval dye, indigo. Pyrrole is also the structural unit of chlorophyll, the green portion of the pigment of leaves; of haeme, the red portion of the pigment of blood; of the pigments of the bile; and of the pigments of numerous types of bacteria, algae and other living organisms. Pyrrole pigments are found in coal, petroleum and similar substances derived from plant and animal sources.

The colouring matters derived from pyrrole are the objects of extensive scientific investigations because their functions in plants and animals are so critically important to life. Atmospheric carbon dioxide, fixed by photosynthesis involving chlorophyll, is the ultimate source of most of our food and fuel, and the efficiency of transportation of oxygen by the blood pigment, haemoglobin, is indispensable to the rapid motions of higher animals. In addition, these pyrrole pigments are probably produced by living organisms in greater tonnage than any other class of pigments. Derivatives of pyrrolidine, which is completely reduced pyrrole, occur in alkaloids, such as cocaine and nicotine, and as building blocks of proteins in the form of the amino acids proline, hydroxyproline and tryptophane.

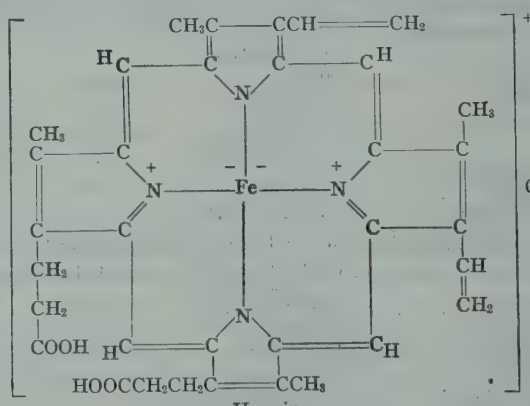
Pyrrole boils at 131° C., is slightly lighter than water (density 0.9669) and has the composition C_4H_5N. It is sparingly soluble in water but dissolves in alcohol, ether and many other solvents. Its structural formula was assigned correctly by the German chemist Adolf von Baeyer in 1870 in the course of his classical investigations on the structure of indigo. It is conventionally represented as in diagram I, while diagram II is the formula of pyrrolidine.



I II

Pyrrole is characterized by great chemical reactivity, being slowly destroyed by air with the formation of a brown pigment. It is also destroyed by strong acids, being partially converted into indole, and it enters into combination with a wide variety of chemical reagents. It has been obtained from bone oil and by destructive heating of proteins but is now available commercially from acetylene, formaldehyde and ammonia. Pyrrole is moderately toxic, acting as a nerve poison. Certain of its derivatives have found a limited application in medicine. Their main use is in organic chemical synthesis for the study of the structure and functions of the naturally occurring pigments.

The most important pyrrole derivatives are the porphyrins (from the Greek for purple) and the chlorins (from the Greek for yellow-green) and their metallic compounds. A typical iron-porphyrin compound is haemin, the oxidized form of the coloured portion of the blood pigment. The chemical formula for this substance was elucidated mainly by researches directed by Wilhelm Küster, Richard Willstätter and especially Hans Fischer; its complete synthesis was accomplished by the latter and his co-workers in 1929. The formula may be conventionally represented as follows:



Haemin

See Hans Fischer and Hans Orth, *Die Chemie des Pyrrols* (Leipzig, 1934–40). (A. H. CN.)

PYRUVIC ACID or PYRORACEMIC ACID is an extremely reactive organic acid which occupies a central place in cellular metabolism. Formed during sugar fermentation, it may be oxidized to acetic acid; or it may be reduced: (1) to lactic acid (glycolysis); (2) to ethyl alcohol (alcohol fermentation) through decarboxylation to acetaldehyde; (3) to malic acid by CO_2 fixation; or (4) to alanine, by NH_3 fixation. The oxidation of pyruvic acid in living cells requires the presence of vitamin B_1 (thiamine), and its concentration in the blood increases in vitamin B_1 deficiency.

Pyruvic acid, $CH_3COCOOH$, is best prepared by heating together a mixture of six parts of fused potassium hydrogen sulphate and four parts of tartaric acid at 210°–220° C. The distillate is fractionated under reduced pressure, the yield being 50%–55%. Pyruvic acid was first obtained by J. J. Berzelius in 1835 by the dry distillation of tartaric acid. It is a liquid boiling at 75°–80° C./25 mm. and at 165° C./760 mm. with partial decomposition; on redistillation at 60° C./10 mm. it forms crystals which melt at 13.6° C. With phenylhydrazine it gives crystalline phenylhydrazone, and it combines additively with prussic acid and with alkali bisulphites. It forms mercaptals with mercaptans, and is oxidized to acetic acid with hydrogen peroxide in neutral and with ceric sulphate in acid solutions. Its most characteristic reaction with aldehydes and aromatic amines (Doebner's reaction) leads to the production of arylcinchonic acids. It can be tested for by reduc-

tion to lactic acid through the action of magnesium and an acid.

PYRZYCE (Ger. *Pyritz*), a town in the province of Szczecin, Pol., formerly in the Prussian province of Pomerania, Ger., 16 mi. S.W. of Starogród by the railway to Kostrzyn. Pop. (1939) 11,200, (1946) 803. It became a town in 1150 and was surrounded by walls with towers. Near the town was the spring in which Otto, bishop of Bamberg, baptized the first Pomeranian converts to Christianity in 1124.

PYTHAGORAS (6th century B.C.), Greek philosopher, was a native of Samos and flourished about 532 B.C. He is said to have been a pupil of Pherecydes (*q.v.*). In Ionia he had the reputation of a learned and universally informed man. "Of all men," says Heracleitus, "Pythagoras, the son of Mnesarchus, was the most assiduous inquirer." The extensive travels attributed to Pythagoras are no doubt mostly apocryphal, but there is no intrinsic improbability in the statement of Isocrates (*Laud. Busir.*, 28, p. 227 Steph.) that he visited Egypt and other countries of the Mediterranean. The historically important part of the career of Pythagoras begins with his migration to Croton, a Dorian colony in southern Italy, about the year 529. According to tradition, he was driven from Samos by the tyranny of Polycrates. At Croton Pythagoras became the centre of a widespread organization which was, in its origin, a religious brotherhood or an association for the moral reformation of society rather than a philosophical school. The Pythagorean brotherhood had much in common with the Orphic communities which sought by rites and abstinences to purify the believer's soul and enable it to escape from the "wheel of birth." Its aims were those of a religious order rather than a political league. The new order did indeed establish for a time its supremacy over a considerable part of Magna Graecia, but this entanglement with politics led in the end to the dismemberment and suppression of the society. The first reaction against the Pythagoreans, led by Cylon, seems to have taken place in the lifetime of Pythagoras in connection with the victory gained by Croton over Sybaris in 510. Cylon was able to bring about the retirement of Pythagoras to Metapontium, where he remained until his death at the end of the 6th or the beginning of the 5th century. The order appears to have continued powerful in Magna Graecia till the middle of the 5th century when it was violently trampled out. The meetinghouses of the Pythagoreans were everywhere sacked and burned; mention is made in particular of "the house of Milo" in Croton, where 50 or 60 Pythagoreans were surprised and slain. Those who survived took refuge at Thebes and other places. Lysis went to Thebes, where he became the instructor of Epaminondas. Philolaus, too, who according to tradition wrote the first exposition of the Pythagorean system, lived at Thebes at the end of the 5th century. Philolaus, however, and some others were afterward able to return to Italy, and thenceforth Taras (Tarentum) became the chief seat of the school. There Archytas, the friend of Plato, lived; he ruled Taras for years and was never defeated in battle. As a philosophic school the Pythagoreans became extinct about the middle of the 4th century.

Aristotle in his accounts of Pythagorean doctrines never refers to Pythagoras but always to "the Pythagoreans" or "the so-called Pythagoreans" (οἱ καλούμενοι). Nevertheless certain doctrines may be traced to the founder. Foremost among these is the theory of the immortality and transmigration of the soul (*see* METEMPSYCHOSIS). Pythagoras's teaching on this point is connected with the primitive belief in the kinship of men and beasts, a view which Pythagoras also held. The Pythagorean rule of abstinence from flesh is thus, in its origin, a taboo resting on the blood-brotherhood of men and beasts; and a number of the Pythagorean rules of life which are found embodied in the different traditions appear likewise to be genuine taboos belonging to a similar level of primitive thought. The moral and religious application which Pythagoras gave to the doctrine of transmigration continued to be the teaching of the school. The view of the body (σῶμα) as the tomb (σῆμα) of the soul and the account of philosophy in the *Phaedo* as a meditation of death are expressly connected by Plato with the teaching of Philolaus; and the strain of asceticism and other-worldliness which are met there and elsewhere in Plato is usually traced to Pythagorean influence.

Theory of Numbers.—The scientific doctrines of the Pythagorean school have no apparent connection with the religious mysticism of the society of their rules of living. Their discourses and speculations all connect themselves with the idea of number, and the school holds an important place in the history of mathematical and astronomical science. Aristotle tells us that the Pythagoreans "applied themselves to the study of mathematics and were the first to advance that science; insomuch that, having been brought up in it, they thought that its principles must be the principles of all existing things." Pythagoras is said to have attached supreme importance to arithmetic, which he advanced and took out of the region of commercial utility. He also made geometry a part of a liberal education, examining the principles of the science and treating the theorems from an immaterial and intellectual standpoint.

Pythagoras's greatest discovery was, perhaps, that of the dependence of the musical intervals on certain arithmetical ratios of lengths of string at the same tension, 2:1 giving the octave, 3:2 the fifth and 4:3 the fourth. This discovery could not but have powerfully contributed to the idea that "all things are numbers." According to Aristotle, the theory in its original form regarded numbers, not as relations predicable of things, but as actually constituting their essence or substance. Numbers, he says, seemed to the Pythagoreans to be the first things in the whole of nature, and they supposed the elements of numbers to be the elements of all things, and the whole heaven to be a musical scale and a number (*Metaph.*, A. 986 a). Later, *e.g.*, in the fragments of "Philolaus," things are spoken of, not as *being* numbers, but as *having* number and thereby becoming knowable.

The development of these ideas into a comprehensive metaphysical system was probably the work of Philolaus. The elements of numbers referred to by Aristotle were, according to the Pythagoreans, the odd and the even, which they identified with the limit and the unlimited. The unlimited, and therefore the limit also, was conceived as spatial. Numbers were thus spatially regarded, and "one" was identified with the point, which was thus a unit having position and magnitude; "two" was similarly identified with the line, "three" with surface, and "four" with solid. The odd and even and the limit and unlimited were the first two of a set of ten fundamental oppositions postulated by the Pythagoreans, the remaining eight being: one and many, right and left, male and female, rest and motion, straight and curved, light and darkness, good and evil, square and oblong. To the Pythagoreans the universe was in a sense the realization of these opposites. The further speculations of the Pythagoreans on the subject of number rest mainly on fanciful analogies. Thus "seven" is called πάρθενος and Ἀθήνη because within the decade it has neither factors nor products; "five," on the other hand, is marriage because it is the union of the first masculine and the first feminine number (3+2, unity not being considered a number); "one" is identified with reason because it is unchangeable; "two" with opinion because it is unlimited and indeterminate; "four" with justice because it is the first square number, the product of equals.

Aristotle has the interesting remark that Eurytus, who was a disciple of Philolaus, used to assign numbers to all sorts of things such as horses or men, and imitated their shapes by arranging pebbles after the manner of those who bring numbers into the forms of triangles or squares (*Metaph.*, N. 5, 1092 b 10). This leads to figured numbers and the connection between numbers and geometry. The holy tetractys, by which the later Pythagoreans used to swear, was a figure of this kind representing the triangular number 10 and showing at a glance its composition as 1+2+3+4. To add a row of five dots gives the next triangular number with 5 as the side, and so on, showing that the sum of any number of the series of natural numbers beginning with 1 is a triangular number. The sum of any number of the series of odd numbers beginning with 1 is similarly seen to be

a square; thus 3 and 5 added successively to 1 give a figure of this kind  , and so on. If we take the series of even numbers, we see that the sum of any number of them beginning with 2 makes an oblong number .

The successive odd numbers after 1 were called gnomons because the addition of each of them to the sum of the preceding ones (beginning with 1) makes a square number into the next larger square. If the gnomon added to a square is itself a square number, *e.g.*, 9, there is a square number which is the sum of two squares; thus $1+3+5+7=16$ or 4^2, and the addition of 9 ($=3^2$) gives 25 or 5^2, that is, $3^2+4^2=5^2$. Pythagoras himself is credited with a general formula for finding two square numbers the sum of which is also a square, namely (if m is any odd number), $m^2+\{\frac{1}{2}(m^2-1)\}^2=\{\frac{1}{2}(m^2+1)\}^2$. This connects itself with the theorem of the square on the hypotenuse of a right-angled triangle, which tradition universally associates with the name of Pythagoras. This being a property of all right-angled triangles, consideration would show that, while some such triangles have their sides in the ratio of rational numbers, some, and in particular the isosceles, have not.

In the case of the isosceles right-angled triangle the ratio of the hypotenuse to either of the other sides is what is written as $\sqrt{2}$, which is irrational in the sense that its value cannot be expressed exactly as a ratio between numbers. It was the Pythagoreans who discovered the irrationality of $\sqrt{2}$, and not only so, but they discovered the law of formation of the series of side—and diagonal numbers (as they were called), which satisfy the equations $2x^2-y^2=+1$ and so makes it possible to find, as x and y increase, closer and closer approximations to the value of $\sqrt{2}$. The law depends on the proposition in Eucl. ii, 10 to the effect that $(2x+y)^2-2(x+y)^2=2x^2-y^2$, whence it follows that if x, y satisfy one of the above equations, then $2x+y$, $x+y$ is a solution in higher numbers of the other equation. From this is derived $\frac{1}{1}, \frac{3}{2}, \frac{7}{5}, \frac{17}{12}, \frac{41}{29}$, and so on ad infinitum as approximations to $\sqrt{2}$.

Contributions to Geometry.—Other contributions to geometry by the Pythagoreans comprise the following: (1) Pythagoras, it is said, himself formulated definitions in geometry. (2) The Pythagoreans proved that the sum of the three angles of any triangle is equal to two right angles; there is their proof, which, like Euclid's, uses the property of parallels; hence they knew the theory of parallels. (3) They discovered the powerful method in geometry of the application of areas (*cf.* Eucl., i, 44, 45), including application with excess and defect (*cf.* Eucl., vi, 28, 29) which amounts to the geometrical solution of any quadratic equation in algebra having real roots. (4) Pythagoras himself is said to have discovered the theory of proportion (for when Proclus says that he discovered the theory of irrationals, *τῶν ἀλόγων*, the reading should almost certainly be *τῶν ἀνάλογον*, of proportionals) and of the three means, arithmetic, geometric and harmonic. The arithmetic and harmonic means are shown in the middle terms of the proportion $a: \frac{a+b}{2}=\frac{2ab}{a+b} :b$, a particular case being $12:9=8:6$, from the terms of which the three musical intervals can be obtained. The Pythagorean theory of proportion was arithmetical (after the manner of Euclid, book vii) and did not apply to incommensurable magnitudes; it must not therefore be confused with the general theory due to Eudoxus which is expounded in Euclid v. (5) Proclus also says that Pythagoras discovered the construction of the five regular solids. It was more probably Theaetetus who (as another scholium says) discovered the octahedron and the icosahedron; but the Pythagoreans were clearly acquainted with the pyramid or tetrahedron and the dodecahedron. The construction of the dodecahedron requires that of a regular pentagon, which again depends (as in Eucl., iv, 10, 11) on the problem of Eucl., ii, 11 about the division of a line in extreme and mean ratio, a particular case of the application of areas. The assumption that the Pythagoreans could construct a regular pentagon is confirmed by the fact that the pentagram, the triple interwoven triangle, or the star-pentagon, was used by the Pythagoreans as a symbol of recognition between the members of the school and was called by them health. (6) The Pythagoreans discovered how to construct a rectilineal figure equal to one and similar to another rectilineal figure.

Summing up the Pythagorean geometry, it may be said that it covered the bulk of the subject matter of Euclid's books i, ii, iv, vi (and probably iii), with the qualification that the Pythagorean theory of proportion was inadequate in that it did not apply to incommensurable magnitudes.

Pythagorean Astronomy.—It remains to speak of the Pythagorean astronomy. Pythagoras was one of the first to hold that the earth and the universe are spherical in shape. He realized that the sun, moon and planets have a motion of their own independent of the daily rotation and in the opposite sense. It is improbable that Pythagoras himself was responsible for the astronomical system known as Pythagorean, which deposed the earth from its place in the centre and made it a planet like the sun, the moon and the other planets; for Pythagoras apparently the earth was still at the centre. The later Pythagorean system is attributed alternatively to Philolaus and to Hicetas, a native of Syracuse. The system may be thus described. The universe is spherical in shape and finite in size. Outside it is infinite void which enables the universe to breathe, as it were. At the centre is the central fire, called the hearth of the universe (among other names), wherein is situated the governing principle, the force which directs the movement and activity of the universe. In the universe there revolve around the central fire the following bodies: nearest to the central fire is the counterearth which always accompanies the earth; next in order (reckoning from the centre outward) is the earth, then the moon, then the sun, then the five planets and then, last of all, the sphere of the fixed stars. The counterearth, revolving in a smaller orbit than the earth, is not seen by us because the hemisphere in which we live is always turned away from the counterearth (the analogy of the moon which always turns the same side to us may have suggested this). This part of the theory involves the assumption that the earth rotates about its own axis in the same time as it takes to complete its orbit around the central fire; and as the latter revolution was held to produce day and night, it is a fair inference that the earth was thought to revolve around the central fire in a day and a night, or in 24 hr.

The system amounts to a first step toward an anticipation of the Copernican hypothesis, and Copernicus himself referred to it as such. The curious thing in the system is the introduction of the counterearth. Aristotle in one place says that its object was to bring the number of the revolving bodies up to ten, the perfect number according to the Pythagoreans; but elsewhere he hints at the truer explanation when he says that eclipses of the moon were considered to be sometimes a result of the interposition of the earth, sometimes of the interposition of the counterearth, whence it would appear that the counterearth was invented in order to explain the frequency of lunar eclipses as compared with solar.

PYTHAGORAS, of Rhegium, a noted Greek sculptor of the 5th century B.C., a contemporary of Myron and Polyclitus, and their rival in making statues of athletes. One of these, that of the boxer Euthymus of Locri, can be dated at 472 B.C. He was born at Samos and migrated in his youth to Rhegium in Italy. He made a statue of Philoctetes notable for the physical expression of pain, an Apollo shooting the Python at Delphi, and a man singing to the lyre. His technical improvements went far to ending archaic stiffness. No existing work can be certainly attributed to him, but the "Apollo on the Omphalos" at Athens and the "Choiseul-Gouffier" Apollo in the British Museum have been identified as copies of his statue of Euthymus.

See Waldstein in *J.H.S.* i, 168; E. A. Gardner, *Handbook of Greek Sculpture* (London, 1915).

PYTHEAS, of Marseille (*Massilia*), Greek navigator and geographer, was probably contemporary with Alexander the Great; his work is lost, and consequently its form and character are not known, but the various titles under which it is quoted (*e.g.*, *Γῆς περίοδος*, or *Τὰ περὶ τοῦ Ὠκεανοῦ*) point to a geographical treatise, in which Pytheas had embodied the results of his observations, rather than to a continuous narrative of his voyage.

Some modern writers supposed Pytheas to have been sent out, at public expense, by the republic of Massilia; but there is no ancient authority for this, and Polybius states that he had undertaken the voyage in a private capacity and with limited means. All that is known concerning the voyage of Pytheas is contained in a brief passage of Polybius cited by Strabo, according to which Pytheas had not only visited Britain, but had "travelled all over it on foot," and estimated its circumference at more than 40,000 stadia (4,000 geographical miles). To this he added the account of Thule (which he placed six days' voyage north of Britain)

and the adjoining regions. After this he visited "the whole of the coasts of Europe" (*i.e.*, those bordering on the ocean) as far as the *Tanais*. Some modern writers suppose that he made two different voyages, but this is improbable; the expressions of Polybius imply that his explorations in both directions, first toward the north and afterward toward the east, formed part of the same voyage.

The countries visited by Pytheas, were previously unknown to the Greeks and were not visited again for two centuries. Thus some of the later Greek geographers altogether disregarded his statements, and treated his voyage as a fiction. In modern times a critical examination has been more favourable and the tendency of modern critics has been to exaggerate the value of Pytheas's work. Speculation has dealt chiefly with his "Thule," believed differently to be Norway, Iceland, or the Shetlands; and "Cassiterides" (Tin islands, perhaps St. Michael's mount in Cornwall).

Pytheas had one special merit; he was a good astronomer, and was one of the first to fix latitudes. His calculations of the length of the longest day at four different points in the neighbourhood of Britain are probably based on native reports. If these figures (16, 17, 18 and 19 hr.) are to be pressed, they would refer to, say, Ushant (48° N.), Flamborough Head (54°), Tarbet Ness in Ross (58°) and the northernmost Shetlands (61°). Pytheas was also the first among the Greeks to arrive at any correct notion of the tides, and to note their connection with the moon, and their periodical fluctuations. Other observations concerning the manners and customs of the inhabitants of remote northern regions prove that he had himself visited them. Among these are the gradual disappearance of various kinds of grain as one advanced northward; the use of fermented liquors made from corn and honey; and the habit of threshing out corn in barns, instead of on open threshing floors as in Greece and Italy.

BIBLIOGRAPHY.—The fragments of Pytheas have been collected by Arvedson (Uppsala, 1824), and by Fuhr (*De Pythea massiliensi*, Darmstadt, 1835). Of the numerous treatises on the subject, *see* Ukert, "Bemerkungen über Pytheas," in vol. i of his *Geog. d. Griechen u. Römer*, pp. 298–309, which contains an excellent summary of all that is known concerning Pytheas; Sir George C. Lewis, *Historical Survey of the Astronomy of the Ancients*, pp. 466–480 (London, 1862); Sir Edward H. Bunbury, *History of Ancient Geography*, vol. i, ch. xv, § 2 (1883); C. I. Elton, *Origins of English History*, *cf.* especially app. i, pp. 400 ff. (1882); Hugo Berger, *Geschichte der wissenschaftlichen Erdkunde der Griechen*, pt. 3, 2nd ed. (Leipzig, 1903). An elaborate investigation of the subject will be found in Müllenhoff, *Deutsche Alterthumskunde*, i, 211–497 (1870). *See* also Sir Clements Markham's paper, "Pytheas, the Discoverer of Britain," in the *Geographical Journal* (June 1893); and H. F. Tozer, *History of Ancient Geography*, pp. 152–164 (Cambridge, 1897).

PYTHIAS, KNIGHTS OF, a fraternal and benevolent order of secret character, founded in Washington, D.C., Feb. 19, 1864, and chartered by a special act of congress. At mid-20th century the order maintained 56 grand lodges or grand domains in the states of the United States and in provinces of Canada. There were also about 3,000 local or subordinate lodges, including lodges in Hawaii. The governing body is the Supreme Lodge. There were four recognized auxiliary bodies, the military department, the Dramatic Order Knights of Khorassan, the Junior Order Princes of Syracuse and the Pythian Sisters which, founded in 1888, was open to all women relatives of members of the Knights of Pythias.

PYTHIS or **PYTHIUS,** one of the most noted Greek architects of the later age. He cultivated the Ionic style, in which he constructed the temple of Athena at Priene. The dedicatory inscription, which is in the British Museum, records that the founder was Alexander the Great. Pythis also made a great marble quadriga which surmounted the mausoleum.

PYTHON, a snake of the family Pythonidae, and more especially any one of the species of the genus *Python*. The snakes of this genus are large, and its various species are found throughout the tropics of the old world. The snakes of the python family are distinguished from the boas (*q.v.*), with which they are often confused, by the presence of the supraorbital bone in the skull. As in the boas, vestiges of the hind limbs are present, visible externally as a pair of claws adjacent to the anal cleft. The teeth are strong and adapted for catching and holding the prey. There is no venom or venom-conducting apparatus.

Killing of the prey is effected by constriction; one or more coils of the body are thrown around the victim, following up the stroke of the head, and pressure is applied by the powerful body muscles. The pressure exerted by a large python must be terrific. The prey is killed, however, by suffocation rather than by any actual crushing of the ribs. During the swallowing process much saliva is secreted, and should the prey be disgorged, as may happen if the snake is disturbed, it will be found to be covered with this secretion. This evidently accounts for the fable that pythons cover their prey with saliva before swallowing it.

There can be no doubt that large pythons are strong enough to kill an animal the size of an ox, but stories of their killing and eating cattle and horses are not to be credited. The prey is swallowed whole, and though the mouth is greatly distensible, it cannot be stretched beyond the calibre of a moderate-sized pig. Authentic accounts of attacks on man are extremely few.

Most pythons are partly arboreal and are likely also to be found in the vicinity of water, in which they lie and soak. Reproduction is by means of leathery-shelled oval eggs, of which there may be a hundred or more in a clutch. The eggs are laid in a heap and are guarded and incubated by the mother, who coils herself around them, and who is known from observation in zoological gardens to have a higher body temperature than the surrounding air while so occupied.

The largest species is the reticulated python (*Python reticulatus*) of the Malay region, which occasionally reaches a length of 30 ft. The Indian python (*P. molurus*) is frequently seen in zoological gardens, as is the African rock python (*P. sebae*). Other members of the python family include the remarkable arboreal green python of New Guinea (*Chondropython viridis*) and various other Australasian types. Two species (*Loxocemus*) inhabit western Mexico, as the only American members of the family. (H. W. P.; K. P. S.)

PYTHON, a huge serpent, nameless and female in the earliest account (*Hymn. Homer* iii, 300 *et seq.*), which was killed by Apollo at Delphi (older name Pytho), either because it would not let him come near the oracle—in one version (Hyginus, *fab.* 140), it used itself to give oracles—or because it persecuted his mother Leto during her pregnancy. It is generally said to be the child of Earth (Hyg., l.c.), and in all probability is to be connected with the reliable tradition (*e.g.*, Aesch., *Eumen.*, 1–8) that there was an oracle of Earth at Delphi before Apollo came.

In Hellenistic belief, a python was a spirit which possessed certain persons and prophesied unknown to them through their mouths (Hesychius, *q.v.*).

See Farnell, *Cults of the Greek States*, iii, 9; iv, 180; also Preller-Robert, i, 239.

PYTHONOMORPHA, the mosasaurs, a group of large marine lizards of Upper Cretaceous age. (*See* REPTILES.)

PYX, a term for various forms of receptacles (Gr. πυξίς, a box or chest). In ecclesiastical usage it is the sacred vase or tabernacle in which the Host is reserved. In the English mint the pyx is the chest in which are placed one coin from every 15 lb. of newly coined gold and one from every 60 lb. of newly coined silver to await the "trial of the pyx" (*see* MINT). This chest was formerly kept in the Chapel of the Pyx in Westminster abbey.

Q THIS letter corresponds to Semitic ϕ (*koph*) and Greek ϙ (*koppa*). The form of the majuscule has been practically identical throughout its known history. In the form found on the Moabite stone the vertical stroke extended to the top of the loop and the same is the case with an early form ϕ from the island of Thera. The Etruscan form was identical with the Greek. The letter did not occur in the Ionic alphabet. The Latin alphabet had two forms Ϙ and Q.

In the minuscule form the stroke has moved to the right side of the letter owing to the speed of writing. This produced the cursive form ϙ occurring in the 6th century A.D. Uncial writing also had the form ϙ and the Carolingian form was practically identical.

In Semitic the sound represented by the letter was an unvoiced guttural pronounced further back than that represented by the letter *kaph*. In Greek the letter was largely redundant, and in the eastern alphabet was entirely superseded by *kappa*.

CLASSICAL LATIN AND ONWARDS		Q

THE DEVELOPMENT OF THE LETTER "Q" FROM THE EARLIEST TIMES

In the Chalcidic alphabet it lingered and was taken over from this into Latin, where it became stereotyped for use only before the letter U in words in which the unvoiced labio-velar occurred, represented by the combination of these letters. The combination of these two letters holds to the present day, and in modern English Q is not used unless followed by U, even if, in words such as *oblique*, the sound is a simple velar and not a labio-velar. The most usual position of the sound is initial in words such as *queen, quick*. Q is used apart from U only very rarely in words of foreign origin, especially to represent a Semitic guttural, as in Qabala, 'Iraq. (B. F. C. A.)

QABES: *see* GABES.

QAIN is the administrative headquarters of the very extensive district of Qainat, the southeastern portion of the province of Khurasan in Iran. This district has the province of Kerman on the south and extends eastwards to the frontier of Afghanistan. The region in which Qain is situated consists mainly of a complicated system of hill ranges of mean elevation 4,000 ft. running north to south and sinking down in the south to the Seistan basin. It is without perennial rivers, the drainage flowing westward to the Dasht-i-Lut. The rainfall is greater than that of Kerman province, which has an average fall of 4.7 inches, and the population depend largely on *deimi* crops, *i.e.*, those which are not artificially watered. Great numbers of camels are reared and the principal products are grain, saffron, wool and opium; the asafoetida plant also grows very profusely.

The town of Qain is situated about 200 mi. south of Meshed on the excellent main road to Zahidan (Duzdab), in a broad valley, in 33° 42′ N., 59° 8′ E., at an elevation of 4,500 ft. The population is variously estimated at 5,000–15,000; the town, surrounded by a mud wall with bastions in disrepair, appears to have considerably increased in size and importance in recent years, so that the houses of the wealthier inhabitants are found without the walls. The cultivation of saffron is a specialty of the immediate neighbourhood which supplies nearly the whole of Iran with this commodity. The chief industries are the making of felts and carpets, but the best Qaini carpets are made at Darakhsh northeast of Birjand. Southeast of the town, on the summit of two hills rising 500 ft. above the valley, are the ruins of a great fort about 600 yards in length. Qain is undoubtedly a place of great antiquity and chequered history. The present town was built by Shah Rukh to replace an older town which he is said to have destroyed. After a time the Uzbegs took possession of and held the place until Shah Abbas I (1587–1629) expelled them. In the 18th century it fell under the sway of the Afghans and was a dependency of Herat until 1851.

See P. M. Sykes, "A fourth journey in Persia, 1897–1901," *Geogr. J.* (1902) xix, pp. 119–73; *see* also KHURASAN. (P. Z. C.; X.)

QAIRWĀN (KAIROUAN, KAIRWAN), the sacred city of Tunisia, 36 mi. southwest from Sousse, and about 80 mi. due south from Tunis. Qairwān, in shape an irregular oblong, is surrounded by a crenellated brick wall with towers and bastions and five gates. The city, however, spreads beyond the walls, chiefly to the south and west. Some of the finest treasures of Saracenic art in Tunisia are in Qairwān. The chief buildings are the mosques, which are open to Christians, Qairwān being the only town where this privilege is granted. It is served by a branch of the metre-gauge railroad from Kasserine to Sousse.

In the northern quarter stands the great mosque founded by Sidi 'Oqba ibn Nafi, containing his shrine and the tombs of many Tunisian rulers. It was several times rebuilt; that which subsists dates from the period of the Aghlabites (3rd century of the Hegira, 9th century of the Christian era). Like the primitive mosques of Islam, it consists of a rectangular hypostylar hall preceded by a courtyard surrounded by porticoes on all sides. The gateway on the N.E., named the gate of Lella Rejana, is preceded by a beautiful square porch, decorated with ancient columns. In the middle of the northern side of the courtyard rises a massive square minaret.

The Mosque of Sidi 'Oqba is the prototype of many other notable mosques. (*See* MOSQUE.) Of greater external beauty than that of Sidi 'Oqba is the Mosque of the Three Gates. Cufic inscriptions on the façade record its erection in the 9th and its restoration in the 15th century A.D. Internally, the mosque is a single chamber, supported by 16 Roman columns. One of the finest specimens of Moorish architecture in Qairwān is the *zawia* of Sidi Abid-el-Ghariani (d. *c.* A.D. 1400), one of the Almoravides, in whose family is the hereditary governorship of the city. The entrance, a door in a false arcade of black and white marble, leads

into a court whose arches support an upper colonnade. The Mosque of the Companion (*i.e.*, of the Prophet), outside the walls to the northwest, is also important. This mosque is specially sacred as possessing what are said to be three hairs of the Prophet's beard, buried with the saint, who was one of the companions of Mohammed. (This legend gives credence to the belief that the tomb contained the remains of Mohammed's barber.) The mosque consists of several courts and chambers, and contains some beautiful stained glass.

The town is the centre of fairly active trade and industry, especially in leather goods and carpets. Its suks are interesting but less important than those of Tunis. The town in 1936 had a population of 22,991, of whom 21,902 were Moslems.

The legend says that 'Oqba in A.D. 671 (A.H. 50) determined to found a city as a rallying point for the followers of Mohammed in Africa. He led his companions into the desert and, having exhorted the serpents and wild beasts, in the name of the Prophet, to retire, he struck his spear into the ground exclaiming "Here is your Qairwān" (resting place), so naming the city. In the 8th century Qairwān was the capital of the province of Ifrikia. Later it became the capital of the Aghlabite princes, thereafter following the fortunes of the successive rulers of the country. (*See* TUNISIA: *History.*) After Mecca and Medina, Qairwān is the most sacred city in the eyes of the Mohammedans of Africa, and constant pilgrimages are made to its shrines.

In World War II, the axis took over, in Nov. 1942, the railway and important adjacent airfields which were subjected to Allied bombing. The British 1st army, re-enforced by U.S. troops, took the city on April 11, 1943.

See Murray's *Handbook to Algeria and Tunis,* by Sir R. L. Playfair (1895); H. Saladin, *Tunis et Kairouan* (1908); Georges Marcais, *Manuel d'art Mussulman,* Tome I (1926). (P. W. I.)

QAIS, an island in the Persian gulf lying about 10 m. off the mainland of Iran in 54° E.; it is the site of a trade emporium of great importance in former times. The island measuring 10 m. by 5 m., rises 120 ft. above sea level to a plateau and is bare of vegetation except for small patches of cultivation and a few date groves and stunted herbage. It is surrounded by a reef and pearl banks. The normal population is estimated at about 2,000 chiefly Arabs of the Al Ali tribe, who largely engage in pearl fishing.

Qais is an arabicized form of the Persian Kish; and is the Kataia of Arrian. In the Mohammedan period it formed a part of the province of Fars, but it was only in the later middle ages that the place attained importance, when a prince of South Arabian origin obtained possession of it, built a fleet there, and gradually extended his power. He captured Siraf (modern Tahiri 27° 40′ N., 52° 20′ E.) which was then the principal emporium of the Persian-Indian-Chinese trade. Siraf gradually—in the first half of the 11th century—became more and more deserted under the suzerainty of the princes of Qais, as they diverted the very considerable trade from the captured Persian sea-port to their own island, and finally Qais supplanted Siraf.

At its period of greatest power, the dynasty of Qais also ruled over the district of Oman on the opposite Arabian shore. The Rabbi Benjamin of Tudela visited Qais between A.D. 1164–73, and noted the rich market of the island whose chief business was the exchange of Persian, Mesopotamian, Arabian and Indian manufactures and produce. The site of the old city is marked by the ruins known as Harira on the north coast. Qais in turn lost its importance—for what reason is not precisely known—somewhere in the 14th century, and its trade passed to Hormuz.

See W. Ouseley, *Travels in various countries of the East,* vol. i. (1819); A. W. Stiffe, "Ancient trading centres of the Persian Gulf. Kais." *Geogr. J.,* 1896, VII.; A. T. Wilson, *The Persian Gulf* (1928). (P. Z. C.)

QARAITES or **KARAITES** (Hebr. *Benē Miqrā',* sons of the Scripture), a mediaeval Jewish sect claiming to return to primitive Judaism by restoring the Scriptures to their rightful place now usurped by tradition (the Oral Law). Neither historically nor spiritually have they any connection with the Sadducees, the Samaritans or with Schechter's Jewish Sectaries of Damascus. Karaism was an anti-Rabbinic religious innovation prompted by politics, but the Karaites have always endeavoured to prove their antiquity and to trace their origin to former sects that had existed and decayed before Karaism arose. The founder, Anan ben David of Baghdad, in 760 claimed to succeed Isaac Iskawi his uncle as Exilarch, but the *Geōnim* (*see* GĀON) ultimately chose Anan's younger brother Josiah, whose appointment was confirmed by the Caliph al-Manṣūr. Anan proclaimed himself as anti-exilarch and succeeded in enlisting the support of various sects such as the Isawites, the Yudganites and the Shadganites. This act on the part of a *dhimmi* in Islam was treasonable. In 767 Anan was arrested but saved from execution by the advice of a fellow-prisoner, the famous Abu Hanifa. Anan pleaded that his was a new religion which venerated Islam and followed Muslim law in many ways, *e.g.,* in fixing the calendar by observation instead of by calculation. In 770 he published his code (*Ṣēfer ham-Miṣwōth*). Ultimately he led his followers to Jerusalem, whence they spread over Egypt, Syria and S. Russia. They have never been numerous and now number about 14,000.

The chief points of difference with the Rabbanites were the calendar, Sabbath and marriage laws. Karaism had a great effect on the body of Judaism: polemics stimulated learning. Sa'adya of Fayyum was one of the notable scholars who challenged Karaite exegesis. The Karaites possessed a number of scholars of considerable distinction, especially in the direction of Hebrew philology, biblical exegesis (*e.g.,* Yepheth ibn 'Ali) and philosophy of religion (*e.g.,* Isaac b. Abraham Troki, 1533–1594, author of the *Ḥizzūq 'emūnah*). Their liturgy is jejune, being composed almost entirely of scriptural excerpts and possessing practically no hymns. Nevertheless this constitutes no general reflection on Karaite intellectualism. No movement can be considered barren from the literary standpoint that has produced writers such as Benjamin Nahawandi (*c.* 850), Abu Yusuf al-Qirqisani (tenth cent.) and his contemporaries Sahl ibn Maṣliaḥ, Solomon ibn Yeroḥam, Yusuf ibn Nuḥ, Aaron ben Elijah of Nicomedia (b. 1300), Elijah ben Moses Bashyazi (1420–90), Caleb Afendopoulo (end of 15 cent.) and, latterly, Abraham Firkovitch (1786–1874). The latter dimmed his splendid reputation for scholarship and lowered the value of his enormous archaeological activity by partisan conduct. He discovered in the Crimea very many mss. and tombstones of considerable antiquity but he tampered with the dates and colophons to prove the age of the Karaites and their claims to represent true Judaism. Largely owing to his efforts, the Karaites were exempt from the religious persecution from which the Russian Jews (Rabbanites) suffered. A notable controversy arose in consequence of his discoveries, which were more or less categorically impugned by H. L. Strack and A. Harkavy (lit. *s.v.* Firkovitch in *Jew. Enc.*) but upheld (with reservations) by D. Chwolson (*Corp. Inscrip. Hebr.,* St. Petersburg, 1882). The recent Masoretic researches of Paul Kahle (e.g., *Masoreten d. Westens,* Stuttgart, 1927: *Hebr. Bibelhandschriften aus Babylonien,* Giessen, 1928) incline to the latter view.

BIBLIOGRAPHY.—*See* the various articles in *Jew. Enc.* and Hastings' *E.R.E.* and articles in *Jew. Quart. Rev.*

QARO (or CARO), **JOSEPH BEN EPHRAIM** (1488–1575), codifier of Jewish law, whose code is still authoritative with the mass of Jews, was born in 1488. As a child he shared in the expulsion from Spain (1492), and like most prominent Jews of the period was forced to migrate from place to place. In 1535 he settled in Safed, Palestine, where he spent the rest of his life. Safed was then the headquarters of Jewish mysticism. Qaro's mysticism did not take the form of a revolt against authority, but was rather the spiritual flower of pietism. It is, however, as a legalist that Qaro is best known. In learning and critical power he was second only to Maimonides in the realm of Jewish law. He was the author of two great works. In the earlier and greater book, in the form of a commentary (entitled *Beth Yoseph*) on the *Turim* (*see* 'ASHER BEN YEHIEL) designed exclusively for specialists, Qaro shows an astounding mastery over the Talmud and the legalistic literature of the middle ages. He felt called upon to systematize the laws and customs of Judaism in face of the disintegration caused by the Spanish expulsion. But the *Beth Yoseph* is by no means systematic. Qaro's real aim was

effected by his second work, the *Shulḥan 'Arukh* ("Table Prepared"). Finished in 1555, this code was published in four parts in 1565. The work gradually became the almost unquestioned authority of the whole Jewish world. Its influence was to some extent evil. It "put Judaism into a strait-jacket." Independence of judgment was inhibited, and the code stood in the way of progressive adaptation of Jewish life to the life of Europe. But its good effects far outweighed the bad. It was a bond of union, a bar to latitudinarianism, an accessible guide to ritual, ethics and law. It sanctified the home, it dignified common pursuits. When, however, the era of reform dawned in the 19th century, the new Judaism assumed an attitude of hostility to Qaro's code.

QENA, a town of Upper Egypt on a canal about a mile E. of the Nile and 380 mi. S.S.E. of Cairo by rail. Pop. (1937) 34,431. Qena, the capital of a province of the same name, was called by the Greeks Caene in distinction from Coptos, 15 m. S., to whose trade it eventually succeeded. That its modern name should be derived from a purely Greek word seems to point to Qena having originated in a foreign settlement in connection with the Red Sea trade. It is a flourishing town, specially noted for the manufacture of the porous water jars and bottles used throughout Egypt. Its trade in grain and dates with Arabia is all that is left of the extensive commerce formerly maintained between Upper Egypt and India and Arabia.

QISHM, styled by the Arabs as *Jazirat-at-Tawilah* or Long Island, the Oarakta of the ancients, the largest island in the Persian gulf, is in the Strait of Ormuz and separated from the mainland of Iran by Clarence strait, 2 to 15 mi. in width. The island has an extreme length of 68 mi. and average breadth of 10 mi. and is composed of table-topped hills rising to 560 ft. with one peak attaining 1,300 ft. The range on the south is largely composed of rock salt, which is quarried at Namakdan and other places and forms one of the main products. In general aspect the island is parched and barren, but there are fertile patches of cultivation near the villages, producing grain, grapes, dates and melons. The climate is trying to Europeans from May to October.

The total population, mainly of Arab origin, is estimated at 15,000. The chief town is Qishm (pop. 3,000) on the northeastern point, a well-built Arab village which was partially destroyed by earthquake in 1898. It carries on a small coasting trade which (including that of Hanjam island) amounted to 6,300 tons in 1925–26, mainly in fish, fruit and salt. Borings for oil were made by the Anglo-Persian Oil Company during the years 1914–1922 but without result. A light buoy with a flashing light is moored about a mile east of the Portuguese fort, now in ruins. The administration is in the hands of a *shaikh*, an Arab of the Bani Ma'in, who has executive powers under the Iranian authorities.

Basidu, known to British sailors as "Bassadore" is on the northwestern extremity of Qishm, exposed to all winds. The site was ceded to the British Crown in 1817, having been selected, after the suppression of piracy, as a base for the naval squadron responsible for keeping order in the Persian gulf and protecting trade. The station was abandoned in 1823.

QOSEIR, EL, a port on the west coast of the Red sea, just north of latitude 26° north. Not only is this place opposite the region in which the Nile comes nearest to the Red sea but between the Nile and El Qoseir is the Wadi Hammamat, with more water than have the valleys farther south. This district (anciently Rohanu) is rich in diorite, which was quarried for building the great monuments of ancient Egypt and, at least from the days of the 18th dynasty, a caravan route (about 120 m.) left the Nile at Qubti (Coptos), afterwards superseded by Qus and then by Qena, north of Thebes, making for the Red sea where the port of Tuâu (the old El Qoseir) was in use at first, but was later superseded by Sav (El Qoseir) 3 m. to the south-east. It was thence that Egypt sent its ships to Punt for spices, perfumes, gold, incense, ivory, skins, scented woods and precious stones. The town stands on a beach with a coral reef in front giving shelter to small craft; larger ships have to anchor outside.

QUACKERY, the pretensions or practice of a boastful pretender to skill which he does not possess, especially medical skill. Although this dictionary definition does not attach the condition that the quack practises for gain, such is usually the fact.

The existence of quackery pre-supposes four factors (1) an evil, usually an obstinate disease, (2) a sufferer from such an evil, (3) a person—the quack—who claims special knowledge or power to cure the particular evil, (4) a person—the orthodox medical practitioner—who holds out little or no hope of cure. Inasmuch as the sufferer has no knowledge whether the quack or the orthodox practitioner is more justified in his statement and is anxious to leave no stone unturned to be rid of his trouble, there is small cause for wonder that the quack has a great following. Other factors play a part, the desire for cheapness, for the quack medicine or treatment can be obtained—at all events in the first instance—at a relatively low price; rebellion against authority especially when authority gives an unpleasant decision; the hope which, as in the old fable, lies at the bottom of Pandora's box of human ills; the element of mystery which the quack usually employs; the natural repugnance to surgical operation when such is the only remedy recognized by the orthodox practitioner; the desire for secrecy particularly in respect of venereal disorders. It may be imagined from the foregoing that such diseases as cancer, venereal diseases, kidney and bladder complaints, diseases of the skin and respiratory tract, chronic rheumatism, chronic indigestion supply the largest proportion of the quack's clientèle; still, no common disease is free from a fringe of quackery.

The agents employed by quacks in various ages repeat themselves. In the case of cancer, the same chemical substances, the same corrosives have been employed, the same articles of diet have been inculpated over and over again. And though the agents have been shown repeatedly to be useless—even injurious—they come daily under the notice of those whose duty it is to investigate suggested cures and causes of cancer. Other agents are vegetable substances often derived from distant and little occupied parts of the world, called by local names, and for the most part unrecognizable by botanists. The tendency to repetition is unjustifiably taken by the public as a sign of their efficacy in the face of medical antagonism, whereas the truth is that the agents lend themselves to the secrecy which is one of the characteristics of the cancer curer and to the production of a medicine or ointment which can be sold at a price. It is a common story that the "cure" has been handed down from parent to child through many generations and often that it has been imparted to the present owner in return for some remarkable service.

Besides the use of chemical and vegetable substances the quack often turns to profitable account the current scientific tendency of the day. With the advance in knowledge of electricity he builds up what he terms a special form of electrical treatment and though his apparatus may be of the crudest kind and unable to generate electricity in appreciable quantity, the mystery attaching to his method of treatment and the pseudo-scientific language which he employs are not without effect upon the mind of the patient who is already more than half convinced in his favour. Similarly, with the discovery of radium, so-called radium treatments were devised for many complaints in which the amount of radium concerned was in the region of the limit of detectability. In the case of chronic rheumatism "magnetic belts," which give no more than a barely detectable electric current, have been recommended widely, as well as radium plasters which in all contained perhaps a thousandth of a milligram of radium. When it is recognized that the commercial value of such an amount of radium at current prices would be under twopence, the profitable side of such a variety of treatment becomes obvious.

The quack relies largely upon advertisement in newspapers and magazines and most publications of repute exercise scrupulous care in the admission or total exclusion of such advertisements. He is aided, too, by the reluctance of those who have consulted him with disadvantage to acknowledge their action and by the magnification of his successes or apparent successes. Moreover, his powers of diagnosis are negligible and upon strict examination a case of cancer, for example, reported to have been cured always

fails because there is no evidence, either that the case was truly cancer or else that it was truly cured. The one requires microscopical evidence, the other the lapse, according to medical standards, of a period of years—three, five or more.

Quackery flourishes in certain parts more than others. In respect of cancer the mining districts of Northumberland, Durham and South Wales, South Africa, Australia and to a less extent Canada are the source of the greater number of so-called "cancer cures" met with in England, but the proportion is trivial compared with what occurs in Prussia, where it is said that there is one quack to every three orthodox medical practitioners. Recourse to quackery is not the foible of any particular class of society and is compatible with a high level of general intellect. In the case of the wealthy and intelligent it is difficult to feel sympathy for the sufferer in his action, but for the poor and ill-educated who often waste time and money only to find themselves at the end in a hopeless condition, sympathy is great. Yet it is difficult to see how they can be safeguarded. Legislation with regard to quacks and their medicines varies in different countries. In England they are liable if they hold themselves out to be recognized medical practitioners or if death occurs in a person whom they are treating. On the other hand the law considers that a person consults a quack at his own risk; it does not actually forbid the quack from giving advice though he cannot charge for that advice; as a result the financial side is represented by the sale of ointments, apparatus, etc. Elsewhere (*e.g.* in Prussia) legislation has been tried and has failed. The real remedy lies in advancement of medical knowledge and in education.

A word may be said on patent medicines the sale of which is great in all countries. In England they pay a duty but otherwise their sale is unrestricted though limits are imposed upon their composition. The British Medical Association for years has made a practice of analysing patent medicines and attaching to the report of their composition a statement as to the cost of the ingredients; all return to the proprietor a very large margin of profit. Copies of the reports issued from time to time are published under the authority of the Association. Many of these patent medicines are harmless, some are useful; actual fraud, as a rule, is absent. This cannot be said for the quack and his wares.

(W. S. L.-B.)

In the United States the outstanding quacks are located in the large cities; mail-order quackery, like the mail-order house has grown tremendously and it requires a large staff of agents of the post office to make even the slightest inroads on this form of fraud. After some four years of battling in the courts the post office may issue a fraud order against such concerns denying them the use of mails, whereupon they dispose of their wares over the counters of drug stores, and promote them through advertising in the press. Although leading newspapers refuse to carry fraudulent advertisements of cancer and tuberculosis cures, they still carry all sorts of nostrum advertising for coughs, colds, rheumatism and similar complaints.

The use of the testimonial is fundamental to quackery and its advertising. Testimonials, obtainable at a price, have become a current feature in the trade.

In the headquarters of the American Medical Association is a bureau of investigation which carefully investigates the claims made for all new methods of medical treatment. Here is a card index containing 125,000 cards cross-indexing the various forms of quackery practised in the United States. In each of the 48 States there are different laws regulating the practice of medicine; hence quackery varies in each State according to the limits permitted by law. In some States quackery is limited almost entirely to the sale of medicines of secret composition and with claims not justified by the content. In other States quackery is rampant, including not only the sale of patent medicines but the operation of healing institutions conducted by quack doctors, all of the 40 or 50 forms of religious and faith healing, healing by conjuring and by charms, the practice of systems of healing such as chiropractic, naturopathy, naprapathy and similar methods. (M. Fr.)

QUACK-GRASS (*Agropyron repens*), a perennial grass of the barley tribe (Hordeae), called also couch-grass or quitch-grass. It is native to Europe, common in northern Europe and widely naturalized in North America. Quack-grass has bright-green, smooth, stiffly erect stems, 1 to 4 ft. high; leaves with flat or inrolled blades; and terminal flowering spikes, 2 to 6 in. long, composed of numerous, usually five-flowered spikelets, which often bear short awns. Sometimes it is grown for forage, but it is better known as a troublesome weed in cultivated fields, especially on rich soil, spreading rapidly by its extensively creeping greenish-yellow rootstocks. The best method to eradicate it is to plow the land, after it has been left in sod two or more years, just after the flowers appear and harrow at weekly intervals for about 6 weeks.

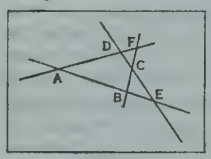
QUACK-GRASS (AGROPYRON REPENS)

QUADRATRIX: *see* CURVES, SPECIAL.

QUADRATURE (from Lat. *quadratura*, a making square), in astronomy, that aspect of a heavenly body in which it makes a right angle with the direction of the sun; applied especially to the apparent position of a planet, or of the moon at first and last quarters. In mathematics, quadrature is the determination of a square equal to the area of a curve or other figure. Integration by quadratures means calculation by a step-by-step process when no analytical expression for the integral is available.

QUADRILATERAL, in geometry, a figure formed by four straight lines. It is said to be plane or skew according as the four lines do or do not lie in one plane. Quadrilateral is also a military term applied to a combination of four fortresses mutually supporting each other. The most famous military quadrilateral was that of the four fortified towns of north Italy—Mantua and Peschiera on the Mincio, and Verona and Legnago on the Adige. This quadrilateral gave Austria a firm hold on Lombardy.



Let us consider the plane figure bounded by four lines terminated at the vertices. A line joining a pair of opposite vertices is called a diagonal. The area of such a quadrilateral is half the product of the length of one diagonal by the sum of the perpendiculars drawn to this diagonal from the other two angular points. The sum of the squares of the four sides of such a quadrilateral is equal to the sum of the squares of its diagonals increased by four times the square of the line joining the midpoints of the diagonals. If the vertices of such a quadrilateral lie on a circle, the product of the diagonals is equal to the sum of the products of the opposite sides.

It is in projective geometry that the quadrilateral plays its most interesting rôle. If *A, B, C, D* are four points in a plane no three of which are collinear, then the lines *AB, BC, CD, DA*, each taken to be of indefinite extent, form a quadrilateral. These sides intersect in pairs not only in the four given points (called vertices) but also in a point *E* on both *AB* and *CD*, and in a point *F* on both *BC* and *AD*. The points *E* and *F* are also called vertices. Then each side of the quadrilateral contains three vertices. Two vertices not on the same side are called opposite. A line joining two opposite vertices is called a diagonal. The configuration so described is called a complete quadrilateral. The dual figure is called a complete quadrangle. These figures are of fundamental importance in projective geometry (*q.v.*).

QUADRILLE, the name of a game of cards and of a dance. The game, played by four persons with a pack of forty cards, was a variation of the Spanish game of ombre and superseded it in popularity about 1725, to give way in turn to whist. The dance is of French origin and is usually danced by four couples in square. In the 18th century the *contredanse* was introduced into the ballet,

and groups of four, eight or twelve dancers dressed alike performed different figures; these were first called *quadrilles des contredanses*, later shortened to *quadrilles*. Later the dance became popular outside the ballet, and its figures, five in number, with a finale, bore the names of the different *contredanses, Le Pantalon, l'Été, La Poule, La Trénitz, La Pastourelle.*

QUAESTOR (Lat. *quaerere*, to investigate), a Roman magistrate whose functions, in the later times of the republic, were principally financial, although he was originally concerned with criminal jurisdiction. The quaestorship was probably instituted in 509 B.C. simultaneously with the consulship. The number of quaestors, originally two, was successively increased until Julius Caesar raised it to 40 (45 B.C.); Augustus reduced it to 20, which remained the regular number under the empire. When the number was raised from two to four in 421 B.C., the office was thrown open to the plebeians.

The quaestorship was the lowest of the great offices of State, and hence it was the first sought by aspirants to a political career (*cursus honorum*). The candidate was bound to have completed his 30th year before he entered office, but Augustus lowered the age to 25. Quaestors were elected by the *comitia tributa* (*see* COMITIA) under the presidency of a consul or another of the higher magistrates. They held office for one year, but, like the consuls and praetors, they were often continued in office. Indeed, it was a rule that the quaestor attached to a higher magistrate should hold office as long as his superior; hence, when a consul presided over the city for one year and afterwards as proconsul governed a province for another year, his quaestor also held office for two years. A peculiar burden laid on the quaestors, as a sort of fee exacted from all who entered on the political career, was the paving of the high roads, for which the Emperor Claudius substituted the exhibition of gladiatorial games.

Various classes of quaestors may be distinguished:—

The Urban Quaestors.—Originally the duties of the quaestors, like those of the consuls, were undefined; the consuls were the superior magistrates of the republic, the quaestors their assistants. From a very early time, however, the quaestors possessed criminal jurisdiction; political crimes only seem to have been excepted. The criminal jurisdiction of the quaestors appears to have terminated only when trial by permanent courts (*quaestiones perpetuae*) was extended to criminal cases.

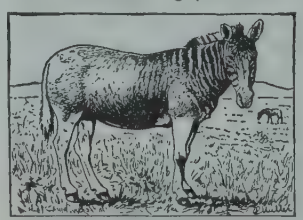
The quaestors had also charge of the public Treasury (*aerarium*, q.v.) in the temple of Saturn, and this was in later times their most important function. They kept the keys of the Treasury and had charge of its contents, the coin and bullion, the military standards, and a large number of public documents, which comprised all the laws as well as the decrees of the senate. Their functions as keepers of the Treasury were withdrawn from urban quaestors by Augustus and transferred to other magistrates.

The Military Quaestors.—These were instituted in 421 B.C. and were clearly distinguished from the urban quaestors by the fact that a non-urban quaestor was assigned as an assistant or adjutant to every general in command, whose name or title the quaestor usually added to his own. Originally they were the adjutants of the consuls only, afterwards of the provincial praetors, and still later of the proconsuls and propraetors. The governor of Sicily had two quaestors; all other governors and commanders had but one. Between the quaestor and his superior, a close personal relation existed, and was not severed when their official connexion ceased. The duties of the military quaestor, like those of the Treasury quaestor, were primarily financial. Moneys due to a provincial governor from the State Treasury were often, perhaps regularly, received and disbursed by the quaestor; the magazines seem to have been under his charge; he coined money, on which not infrequently his name appears alone. But, though his duties were primarily financial, the quaestor was the chief assistant or adjutant of his superior in command, and invested with a certain degree of military power. When the general left his province before the arrival of his successor, he usually committed it to the care of his quaestor, and, if he died or was incapacitated from naming his successor, the quaestor acted as his representative.

The Italian Quaestors.—The subjugation of Italy occasioned the institution (267 B.C.) of four new quaestors, who appear to have been called *quaestores classici* because they were originally intended to superintend the building of the fleet (*classis*); their functions, however, are very imperfectly known.

See Mommsen, *Staatsrecht;* A. H. J. Greenidge, *Roman Public Life* (1901); J. E. Sandys, *Companion to Latin Studies* (1921); W. E. Heitland, *The Roman Republic* (1923).

QUAGGA, an animal of the genus *Equus* (*E. quagga*), allied to Burchell's zebra, formerly met with in vast herds on the great plains of South Africa between the Cape Colony and the Vaal river, but now extinct. The colour of the head, neck and upper parts of the body was reddish-brown, irregularly banded and marked with dark brown stripes, stronger on the head and neck, and gradually becoming fainter until lost behind the shoulder. There was a broad dark median dorsal stripe. The under surface of the body, the legs and tail were nearly white, without stripes. The crest was high, surmounted by a standing mane, banded brown and white.



THE QUAGGA (EQUUS QUAGGA), OF SOUTH AFRICA CLOSELY ALLIED TO THE ZEBRA; NOW EXTINCT

The name is an imitation of the shrill barking neigh of the animal. (*See* ZEBRA.)

QUAHOG: *see* CLAM.

QUAIL, a bird well known throughout Europe, Asia and Africa. The common quail (*Coturnix coturnix*) is variable in colour, but in general is reddish-brown above, marked with dark brown and buff and pale buff below, passing into white on the belly. Essentially migratory, quails breed on the ground, laying 9 to 15 yellowish white eggs, spotted with dark brown. They are very good table birds and immense numbers are netted during the autumn migration across the Mediterranean. Quail is now very rare in Britain, but the numbers fluctuate. It is much the smallest British game bird. It feeds largely on weed seeds, but also eats insects, and is decidedly a beneficial species. Allied species include the rain-quail (*C. coromandelica*) of India; the Australian stubble-quail (*C. pectoralis*); the North American "Bob White" (*Colinus virginianus*); and the Californian tufted quail (*Lophortyx californica*).

The button-quails (*Turnix*) are a somewhat different group, lacking the hind toe in most species. One, *T. sylvatica*, inhabits Barbary and southern Spain; all are confined to the Old World.

QUAIN, SIR RICHARD, BART (1816–1898), Irish physician was born at Mallow-on-the-Blackwater, Co. Cork, on Oct. 30, 1816. After a brilliant career as a student at University college, London, he became assistant physician at the Brompton hospital for diseases of the chest. He served this hospital until his death (March 13, 1898) as full physician (1855–75), and then as consultant. He became physician-extraordinary to Queen Victoria in 1890, and was created a baronet in the following year. Quain's name is remembered by the *Dictionary of Medicine*, the preparation of which occupied him from 1875 to 1882 (3rd ed., 1902).

QUAKERS, originally a cant name applied in derision to the members of the Society of Friends, but now used without any contemptuous significance. It was used as early as 1647, and arose from the physical manifestations of religious emotion characteristic of many early Friends. (*See* FRIENDS, SOCIETY OF.)

QUAKERTOWN, a borough of Bucks county, Pennsylvania, U.S., 38 mi. N. of Philadelphia; served by the Quakertown and Bethlehem and the Reading railways. Pop. (1950) 5,673; it was 5,150 in 1940. It is an agricultural region, and has a number of factories making stoves, hosiery, silk and clothing.

QUALITIES. Primary qualities of matter are, mainly, the spatio-temporal ones, such as shape or motion; secondary ones are the sensible qualities, such as colour or smell. "Tertiary qualities" is a new and convenient term, introduced by Bosanquet, among others, to designate what are commonly called the ultimate values, beauty, goodness, truth.

Primary and Secondary Qualities.—The distinction between primary and secondary qualities is given officially for

British philosophy by Locke (*Essay*, Bk. ii., ch. viii. secs. 9, 10). "Qualities thus considered in bodies are First, such as are utterly inseparable from the body in what estate soever it be; such as, in all the alterations and changes it suffers, all the force can be used on it, it constantly keeps; and such as sense constantly finds in every particle of matter which has bulk enough to be perceived, and the mind finds inseparable from every particle of matter, though less than to make itself singly be perceived by our senses." Locke enumerates: "solidity, extension, figure, motion or rest and number." Secondly, "Such qualities, which in truth are nothing in the objects themselves, but powers to produce various sensations in us by their primary qualities, *i.e.*, the bulk, figure, texture and motion of their insensible parts, as colours, sounds, tastes, etc., these I call secondary qualities." Locke adds that there is a third set of qualities, which are powers to produce changes in other bodies, not merely sensations in us. The distinction of primary and secondary qualities does not originate with Locke. It occurs in Greek philosophy in the doctrine of Democritus: "Sweet and bitter exist by law or convention" (that is, are relative to us); "what exists in reality are the atoms and the void." The atoms, which possess shape and other "primary" qualities, themselves by their density account for such qualities as heavy or hard; but other qualities are the effect upon us of the atoms. Aristotle makes the distinction on a quite different basis, and probably the more valuable one. He distinguishes (*De Anima*, ii., 5) the special sensibles, like colour or taste, which are apprehended by only one sense, from the common sensibles, apprehended by all the senses alike, motion, rest, etc. For modern philosophy, the distinction of primary qualities from secondary ones, in much the same form as Locke's, begins with Galileo, who goes so far even as to say that secondary qualities are but names which we give to things because they excite certain sensations in us (Hoeffding, *Hist. Phil.*, vol. i., p. 183). Locke derived his statement of the distinction from Descartes who, in a famous passage of the *Meditations*, points out how a piece of melting wax changes its colour but always retains extension. Extension he therefore regarded as an essential quality of matter, the sensible qualities being due to us or subjective. Locke puts the matter naïvely in the form, that ideas of figure or motion exactly resemble their original in real things, whereas colour and taste have nothing like themselves in things, and are the work of the mind. As thus drawn, the distinction corresponds to the practice of science and the tradition of the so-called mechanical theory of the world, which has been of such enormous practical value for scientific procedure.

Locke's statement implies that the primary qualities are real and the secondary ones subjective or mental, that is, have no existence apart from the mind; and secondly that the primary qualities are prior in the order of importance and fact to the secondary ones, for the secondary qualities are due to the impingement, however indirect, upon our sense-organs of the primary qualities of the microscopic constituents of matter. Two fundamental questions are therefore raised for philosophy: the relation of the two sets of qualities in respect of reality; are they unequally real, the one independent of the mind and the other dependent on the mind; and secondly their relative status, which of the two is prior in rank in the world of ideas to which they both belong. It is not strange, therefore, that the formulation of the difference between them raises vital questions of philosophy as a whole.

The first question was the immediate interest of Locke's successor, Berkeley, who declared them both to be upon the same level of reality, both being dependent on the mind, or being ideas, that is mental objects. Berkeley had little difficulty in showing first of all that the primary qualities are as much subject to variation with the condition of the observer as the secondary ones; and secondly that the primary ones cannot be experienced apart from the secondary ones—extension must be seen or touched to be experienced. If, then, the secondary ones are mental, so also are the primary ones. Berkeley's contention that both sets are on the same level of reality has been generally accepted by all who have been content to regard both of them as sensible objects. When, as with Kant, a distinction has been readmitted it has been on the ground that extension, for instance, is not a sensible but an *a priori* form of all external sensibles. Granted, however, that they are both on the same level of reality, the primary qualities may still be the more important. But the significance of Berkeley's result for present philosophy lies in this that it leads directly to the question, are the two sets of qualities alike because both are dependent on mind, or because both are equally independent of mind? Now suppose, as simple realism supposes, that what the mind directly experiences is not its ideas but real objects themselves; that instead of holding its objects to be ideas we hold the so-called ideas to be objects themselves; it is still true that primary and secondary qualities are equally real, this time because both are equally independent of mind.

The general metaphysical difficulties of such an idealism as Berkeley's cannot be fully discussed here. But the idealism which has replaced his still declares that reality is experience and even sentient experience (Bradley); and accordingly there is some impatience expressed in either camp when it is asked if secondary qualities are not real. The question still remains whether they are both dependent on mind, or both independent of it. That secondaries are still dependent upon us is maintained even by those realists who urge that, at any rate, they depend if not upon our minds at least upon our bodies, that there would not be colours except there were eyes. The answer made by those realists who maintain that secondaries are as much as primaries independent of mind, is that the bodily organs are instrumental to perception, but are not constitutive, even in part, of the perceived. It is one thing to hold that objects cannot be known without a mind to know them, and another to hold that they owe their existence to mind. The doctrine of behaviourism, which has acquired such strength in American psychology, rests upon the belief that what are called mental acts are nothing but bodily reactions of certain specific sorts to stimulation from objects, and are thus instances of the wider field of organic vital reactions. And some, like the present writer, have expressed the situation for philosophy by saying that in sensation a bodily reaction which is conscious takes place in response to a physical object and that in such action an object or sensum, *e.g.*, a colour, is revealed to the mind. What the exact character of the object in question is may for the moment be deferred.

According to this, secondary and primary qualities alike are independent of mind. An entirely different complexion is put upon the matter in the theory of "neutral monism" advocated by several present philosophers both American (*e.g.*, Holt) and English (*e.g.*, Bertrand Russell). Upon this view the stuff of things is neither material nor mental but neutral; as Bertrand Russell puts it, the mental is more like matter and the material more like mind than is commonly supposed. This doctrine descends from William James who said that physical objects and the ideas of them are but the same thing considered in different relations as, for instance, the same fire may physically destroy a house and mentally suggest the danger of its inhabitants. It is plain that secondary qualities are real on such a view, and that there is no point in asking if they are subjective or objective. Into the grounds of this doctrine there is no space to enter. We may note, however, that it is far closer in its general tendency to idealism as represented by Bradley than it is to any realism which declares that we apprehend objects directly and that we discover what they are in virtue of the specific reactions which the body-mind makes towards them. Without examining neutral monism further we may observe that it stands or falls with its initial statement of experience. When we see a patch of red, it is held that the experience is completely described in the words, a red patch occurs. Is this exact, or must we rather say, I am aware, or there is awareness, of a red patch?

This question must be left, in order to turn to the second question of the order of priority between primary and secondary qualities. No one has ever suggested that the two sets of qualities are upon the same level in this respect. But it is noticeable that in the more recent English philosophy the old priority of the primaries seems to give way to the priority of the secondaries.

Granted that both are equally real, different ways have been adopted of stating their difference. One way is that of G. F. Stout (*Proceedings of the Aristotelian Society,* N.S. vol. iv., 1903–4, p. 153) that "the difference lies in their respective relation to the interaction of material things." The executive order of the material world can be expressed only in terms of the primary and not in terms of the secondary properties of matter. In Bergson's doctrine (*Matter and Memory,* ch. iv.) red differs from the corresponding vibrations in the *tempo* at which the experience is taken by the mind: what at a slower rhythm of *durée* may be apprehended as mechanical vibrations at a faster rhythm is condensed into colour.

But in the important recent philosophy of A. N. Whitehead, although the relative position of the two sets is not discussed as such, the traditional priority of the primaries would seem almost to be reversed in favour of the secondaries. The secondaries are, of course, real. In a happy phrase Whitehead has effectually destroyed the "representationism" inherited from Locke and Descartes by "protesting against the bifurcation of nature into two systems of reality," the one physical, which is not directly known, and the other "which is the byplay of the mind" (*Concept of Nature,* 1920). The world in this philosophy is a world of events, and the simplest events into which the total event which is "the passage of nature" can be resolved are described as "situations" into which "eternal objects," like red or sweet, which are not events, make "ingression." The perception of sense-objects implies a multiple relation into which enter the "percipient event" which is a bodily state, the "situation," the "eternal object" and the surrounding conditions (p. 152). (Compare his *Science and the Modern World,* pp. 99–102.)

The reality of secondary qualities is here not in doubt. The relative position of the primaries and secondaries is not so clear. For space and time on this doctrine are relational, relations between events as thus fully qualified by ingression of eternal objects; and accordingly constructions are framed to describe in terms of concrete events such conceptions as points, areas, volumes, etc.; and the great merit of this procedure is that it starts from concrete events instead of from conceptual entities like points. It is possible thus to define a point by means of all the sets of concrete extensions (*e.g.,* red patches) by which we can approach it. Now, to come to the present question, since space and time are relations between events, they are logically posterior in rank to the events themselves; and it would seem to follow that primary qualities such as geometrical figures, which are enumerated under the head of eternal objects (*Science and the Modern World,* p. 146), are posterior to the secondary qualities which are situated in the events. At least the two sets of qualities appear to be on a different footing. This is, however, not the author's statement but an inference of the writer's, which may be mistaken. We may add that the omission of any analysis or explanation of the vague conception of "relation" makes the whole subject obscure.

A different though allied doctrine, that of the writer (*Space, Time and Deity*), leaves the primary qualities with their traditional priority, while at the same time raising difficulties of its own. According to this view the stuff of the world is space-time itself, that is, pure events, and the qualities or objects, which on Whitehead's doctrine are ingredient into events from the beginning, are said to emerge historically as the web of events within the whole space-time assumes certain complexities of configuration. Primary qualities, such as shapes or numbers, arise within space-time at the earliest level of existence. Subsequently these spatio-temporal configurations assume a certain complexity and we have matter or at least sub-matter. At a higher level of complexity there "emerge" certain material or submaterial configurations, complexes in the end of space-time, which are those conditions of bodies of which we have become aware as colour or taste. The notion of Emergence (*q.v.*) indicates the fact that at certain critical points in the development of the spatio-temporal world, new qualities appear, which are based upon the lower level of existence, and while also equivalent to the lower-level complex are qualified by a new character. So, to take an example from a higher stage of history, a certain complex of chemical and mechanical processes is endowed with the quality life; in the same way as a certain complex of purely spatio-temporal configurations becomes submaterial. Emergence is a term applied by this writer to the large critical novelties only; by Lloyd Morgan it is applied more freely to any change that can be called a change of character. (Whitehead uses the term differently. Since events from the outset are characterized by qualities through the ingression of objects, he speaks naturally of the emergence not of a new quality or "eternal object" but of a new thing through the ingression of a fresh complex of eternal objects.) On this second view, then, secondary qualities emerge from primary ones when those primary qualities, as in material or submaterial things, reach a certain degree and kind of complexity—*e.g.,* when certain motions occur in the body which are propagated in the form of light waves. The grave difficulties, which need not be concealed, in this general doctrine lie in its basis, in its use of the notion of pure event without quality, and its assumption without investigation of geometrical ideas such as point and line.

The Tertiary Qualities or Values raise similar problems, but it may well be doubted whether it is altogether happy to suggest, as the name does, that values belong to things in the same sense as the primary and secondary qualities do. Beauty is the only one of them which belongs directly to things; for truth attaches to propositions, and goodness to actions; and it will be convenient to speak principally of it. It has been held that beauty belongs to the beautiful object itself, a statement which, plausible enough when made of works of art, seems at first only the obvious one to make of a beautiful sunset or any form of natural beauty. Beauty, according to this view, is real and objective like shape or colour. In like manner goodness is held by some to belong to the person or act which is good; and it may be noted that even a writer like Kant treats good as objective though belonging to the intelligible or supra-phenomenal world. The statement that beautiful things have beauty apart from mind is, however, difficult to accept, because in a work of art beauty depends so largely on characters imputed to the work by the artist or the spectator. Thus dead marble looks alive and full of character, or in a picture stable forms are seen, aesthetically, to be in motion, for instance, to be dancing; and in a poem, the words are chosen not merely to describe but to endow: "two voices are there, one is of the sea, one of the mountains," though neither sea nor mountains have voices. There is so far always an element of illusion in art, a character being imputed to the material which it does not possess of itself. Even in natural beauty, the beauty may be seen to depend on selection on our part, or it may be addition; for instance, we may select in the sunset the shades which harmonize, or in the landscape the features which suit our own mood.

It would seem to follow that beauty is really dependent on the mind, and would not exist either in art or nature except for our interference. And it is not difficult to carry this line of reflection further and maintain that goodness and truth are human constructions, as, with respect to goodness, was held by Spinoza. Truth is not so obviously a human invention, but it is, in fact, different from reality itself, though it is guided and controlled by reality. Truth as in science is really a semi-artistic product in which the seeker blends himself with reality and does so by selection. His difference from the artist is that, though he imputes and interprets, he imputes nothing that he cannot verify in the reality. The artist introduces himself into his art giving the work characters which it only has so far as seen with the aesthetic eye. The enquirer who attains truth possesses reality for himself, but he keeps his human imputations out of the product.

The same thing may be concluded from observing that beauty satisfies a specially human impulse which has to make the object which is to satisfy it. Animals, including men, live by using the food which they find; but the impulse to beauty is a creative impulse, which the present writer (*Art and Instinct,* 1927) identifies as the impulse of constructiveness (such as animals and bees

or ants also have) but used without regard to a practical purpose. In the same way truth appeals to an impulse of curiosity, and goodness to a social impulse. The values accordingly possess value because they satisfy these special impulses, and bring a peculiar satisfaction.

Such a conception of beauty and the other values has been held by some critics to be inconsistent with the view that the secondary qualities are independent of mind. If beauty is so dependent, why not colour? The question is really irrelevant, for the same explanation does not necessarily apply to situations which may seem superficially similar. And, as has been indicated, the action in virtue of which we discover colour is entirely different from the creative action by which we become aware of beauty and goodness and truth.

The values therefore rest on a different basis from primary and secondary qualities. Men produce works of art and good societies and true knowledge. But these products have these qualities only on sufferance from their makers. Remove men, and beauty would disappear. But red would remain; though, unless there are creatures with the appropriate organs, it would not be perceived.

At the same time in declaring the values to be qualities only of the new realities which are held upon human tenure, we do not declare them to be mere figments of men. On the contrary, goodness belongs, in the sense described, to acts which bring out what is best in human nature, and true knowledge, being controlled throughout by reality, admits us to the secrets of that reality. And art embodies, in stone or sound, the constructive visions of men and reveals the deeper relations between us and nature.

The separation of tertiary qualities from those which do not depend on human interference helps us to set in a clearer light the quality of things which is their "worshipfulness" and becomes, when considered as abiding in them, the object of religion. It is commonly spoken of as a value along with beauty, goodness, and truth, and may consistently be so regarded, if value is thought to be inherent in what is valuable. If, however, the above considerations are valid, it would be treated, whether under the name of deity, or worshipfulness, or as Otto calls it (in *The Idea of the Holy*, Eng. trans., 1923), "numinousness," not as a value or tertiary quality at all, but, just because it belongs to its possessor intrinsically, without need of human intervention, as a quality, on the line of the primary and secondary qualities, independent of man and actually belonging to the world of things, which world includes, of course, man and man-made values. This topic is, however, raised here only for completeness, and it falls beyond the scope of this article to examine further the nature of deity and its possessor. (S. A.)

QUANTICS, the study of homogeneous algebraic functions of two or more variables which generally contain only positive integral powers of the variables. *See* ALGEBRAIC FORMS.

QUANTITY THEORY OF MONEY. A summary form of expression for two allied but distinct propositions relating to the causes of changes in the value of money. The broader proposition referred to is that, other things being equal, changes in the value of money are dependent upon changes in the quantity of money. The narrower proposition is that changes in the value of money, other things being equal, are *directly* proportional to changes in the quantity of money: so that, if, say, the quantity of money is either halved or doubled, all other things remaining the same, the value of money will be doubled or halved; that is (since the price level is an expression of changes in the value of money) prices will rise or fall in strict proportion to a given change in the quantity of money, all other things being supposed to remain unchanged. It will be clear from what has been said that the narrower proposition cannot be true if the broader proposition is not, but that it by no means follows that the untruth of the broader proposition can be proved by disproving the truth of the narrower.

The controversies to which these propositions have given rise are amongst the most celebrated in political economy. Before approaching them, it must be pointed out that the issues involved are irrelevant for any theory of money which asserts that money is only a symbol *expressing* values, but itself incapable of *possessing* value. Any such theory must reject not only the quantity theory in any form, but also the view (which historically is very important) that the value of money is based upon the cost of production of the precious metals. It must reject the latter alternative by arguing that, though the given form of money may be made from gold or silver, which may possess value, it is not *this* fact which is relevant in deciding whether the coin so made is money or not; the important fact is the denomination of units of value expressed and these are independent of the material out of which money is made. But, though some "symbolistic" theories of money reject the quantity theory, others are so worded as to admit of some form of it; and, in any case, the "quantity theory" and the "cost of production theory" are capable of reconciliation; for it may be argued, as, for example, by J. S. Mill, that "cost of production would have no effect on value if it could have none on supply." Thus a lowering of the cost of production of gold lowers the value of gold and therefore raises prices, because under these circumstances more gold will be produced.

It must be pointed out, further, that the truth of any form of the quantity theory cannot be established purely by an appeal to facts. This is so, not merely because, in practice, other things never are equal—so that, in the real world, changes in the quantity of money are always accompanied by changes, not only in the price level, but in other things—but also because mathematical or statistical equivalences between quantities are incapable of throwing any light upon causal sequence. In other words, assuming that changes in the price level always do accompany changes in the quantity of money, this fact, if it is a fact, does not tell us which change depends upon which. It must be shown, if any form of the quantity theory is true, why changes in the price level are dependent upon changes in the quantity of money. Otherwise it might be argued that changes in the quantity of money are dependent upon changes in the price level, or that changes in the price level and changes in the quantity of money are co-effects of remoter causes.

Though the truth of the quantity theory is not denied by a majority of economists, the formulation of the theory has undergone profound modifications. A distinction must be drawn between the "older" and the "newer" quantity theories. In what follows we shall deal first with the older and traditional theory, and then with its formulation in recent years.

The Older Theory.—The older view, which received its most complete expression at the hands of Irving Fisher in his *Purchasing Power of Money* before the World War (1911), ultimately rests upon the following assumptions. The dynamic consequences of the theory flow from the fact that additional supplies of money *constitute an incentive to additional spending*. Additional supplies of money drive prices up, because (the supply of goods being assumed constant) there will be more to spend and competition among spenders is a cause of rising prices. The additional supplies of money, secondly, *will be spent* because money possesses no intrinsic power of yielding satisfactions; the satisfactions arising from the possession of money can be realized only by acquiring goods and services which possess a direct power of satisfying wants. Now, given these two assumptions, it follows almost as a matter of course not only that prices will rise as the quantity of money rises, but that the price-rise will be in proportion to the increase in the quantity of money. For, given a certain increase in the volume of money and a *disproportionate* alteration of prices, disequilibrium will prevail until the price level is in direct relation to the new total quantity of money. If prices have risen less than in proportion to money, goods will seem unusually cheap to consumers and this will stimulate further consumption of them. If prices have risen more than in proportion to the increased quantity of money, consumers will, in spite of additional quantities of money, find prices unusually high and will check their consumption, with the result that prices will fall. If, but only if, prices alter in exact correspondence to changes in the quantity of money, everyone will find himself in the same position as formerly, with the same real income of satisfaction, but with higher prices on the one hand, and larger money supplies available on the other.

The quantity theory, in the course of its evolution, gradually acquired complexity of exposition. Three separate points have to

be noted in this connection. The first is the modification introduced when changes in the volume of goods are taken into account. Changes in production may be increasing the supply of goods contemporaneously with the increased monetary supply and the latter may even exert some stimulating effect upon production. Other things in this case will not be equal, so that the price level will be forced upwards or downwards according as the influence of increased supplies of money or of goods exerts the preponderating influence; so that the quantity theory is usually expressed in the form that prices move directly with the supply of money and inversely with the supply of goods. Further, it is not the volume of physical goods but the volume of goods *and services* which must be contrasted with the supply of money: an increase in the number of *separate transactions* associated with production works, in this connection, as a price reducing factor, because, in fact, transactions represent services rendered in connection with physical supply. Next, the theory has to take account of the fact that, during a given period of time, each unit of money, passing from hand to hand, necessarily plays a part in the number of transactions, the number depending upon the rapidity of its circulation. Given a certain number of monetary units, an increase in their *velocity of circulation* is equivalent in effect to increasing the supply of units acting as money during the period of time considered, so that an increase in the velocity of circulation, other things being equal, raises prices, whilst a decrease in the velocity reduces prices. Lastly, the quantity theory has to take account of credit instruments of various kinds. Here two solutions are possible. One is to treat these instruments as *additional* to the supply of metallic money and bank and government notes, so that an increase in the supply of credit instruments raises prices in exactly the same way as an increase of money would have done. The second alternative is to regard credit instruments as a *substitute* for ordinary forms of money, which are replaced in a certain number of transactions by credit instruments, so that, *in relation to transactions*, the supply of money rises and prices rise in correspondence.

The New Formulation of the Quantity Theory.—The theory fashionable in pre-war days had two great defects. By contrasting money as a whole with transactions as a whole, it was unable adequately to take account of the individual process of revaluation which is implied in a change in the price level. Secondly, the facts of inflation during the war threw grave doubt on the view that prices were altered proportionately to changes in the quantity of money, the fact being that prices rose much more rapidly in the later stages of inflation, and appreciably less rapidly in the early stages of inflation, than the theory warranted. The new formulations have no difficulty in dealing with these points.

The modern quantity theory starts from the fact that each independent individual or other economic unit requires to keep on hand at all times a certain stock of money. At any moment, of course, money may be passing out of one stock into another, but this does not invalidate the fact that considerations of convenience and habit dictate the keeping of a certain stock on hand. This stock of money on hand or, as Hawtrey calls it, "The unspent margin," is as much required as a stock of clothes or a stock of food, if the economic system is to function adequately. The aggregate demand for money, then, is derived from the sum of individual demands for stocks, just as the demand for houses is derived from the individual demands of those who desire to occupy them. An increase in demand for money is equivalent to an unwillingness to reduce the stock actually held and a desire to add to it. If the supply of money is fixed, this must mean that money acquires a higher value, that is, prices will fall, because people can add to their stocks only by parting with goods or services in order to increase the stock they hold and, since the total stock of money is assumed to be fixed, this can only be at the expense of other stocks held by other individuals. If there is a general desire to decrease stocks on hand, prices must rise, in spite of the total supply of money being fixed, because if there is a general alteration in the desire to hold money, holders can only get rid of what they have by offering it more cheaply, that is, at a lower price in goods to the taker. But this is equivalent to a rise of prices.

When the supply of money alters, the effect produced upon prices depends upon the effect alterations in the supply have upon the willingness to hold stocks. At first the effects of increasing supplies upon the price level, when spent by the issuer, are not in any case likely to be very great. If, at such a time, people's willingness to increase their stocks extends, the rise in the price level will not be in proportion to the increase in the output of money. But if this output increases continuously, the rise in the price level will tend to be more and more rapid and to outstrip the increase in the quantity of money, and that for two reasons. The larger the stock already held, the lower must be the price at which additional amounts must be offered to holders in order to induce them to take more. It may be argued that, as prices rise, individual holders need to hold more, because otherwise the stock held will be inconveniently small in view of the new price level. This is so, but it by no means follows that in the course of the process of adaptation, individuals have not altered their ideas as to what a convenient stock is; in fact, the rise of prices shows that they must have done so. In any case, if the supply of money goes on increasing and prices go on rising, anticipation of the future value of money begins to play an important part. Just as individuals will refuse to add to their stocks of cotton at a time when they believe that cotton will continue to fall in value, so they will refuse to add to their stocks of money at a time when that is falling in value, and unwillingness to add to their stocks is in itself a cause why the fall in the value of money should proceed more rapidly.

It makes no essential difference to the new formulation whether credit is regarded as a form of money or not. If it is so regarded, then the demand for stocks must be regarded as a demand for so much cash plus so much credit. It is thus that the position is treated by Keynes and Hawtrey. If credit is regarded as a substitute for cash, as it is by Cannan, then the demand for cash will fall off if credit arrangements are regarded as more convenient, and in the absence of appropriate arrangements for withdrawing superfluous cash, prices will rise, since part of the stock of cash will have become redundant.

QUANTUM MECHANICS. Throughout the 19th century most physicists regarded Newton's dynamical laws as sacrosanct. During the 20th century it has, however, become increasingly clear that many phenomena, especially those connected with radiation, defy explanation on Newtonian principles. It is well recognized that two major innovations are essential. One of these is the introduction of the principle of relativity. The relativistic corrections are important only for bodies moving with velocities comparable with that of light, and as a result experimental confirmation is possible only in very special types of laboratory experiments or in the cosmological field. The other innovation is quantum mechanics. Although rather less publicized than relativity, the quantum concepts have equally drastic philosophical implications, and furnish richer and more diversified fields for investigation in the laboratory.

Quantum mechanics is the mechanics governing phenomena which are so small-scaled that they cannot be described in classical terms. Thus, quantum rather than Newtonian dynamics must be used in dealing with the motions of electrons or nuclei inside atoms and molecules. In the equations of quantum mechanics, Max K. E. L. Planck's element of action, $h = 6.62 \times 10^{-27}$ erg sec., plays a central role. This constant, which is one of the most important in all of physics, has the dimensions mass$\times$length^2/time. The term "small-scale" used to delineate the domain of quantum mechanics should not be literally interpreted as relating necessarily to extent in space. A more precise criterion as to whether quantum modifications of the Newtonian laws are of importance is whether or not the phenomenon in question is characterized by an "action" (time integral of the kinetic energy) which is large compared to Planck's constant. Thus, if a great many quanta are involved, the Planck idea that there is a discrete, indivisible quantum unit loses importance, just as to a millionaire it would make little difference whether the smallest unit of currency is the cent or the dollar. This fact explains why our ordinary physical processes appear to be so fully in accord with the laws of

Newton. Planck's element of action is, for example, far too fine-grained to have any bearing on the driving of an automobile. Since ultimately all matter is built out of atomic or small-scale ingredients, it must be possible to describe the properties of even large-scale bodies by means of quantum mechanics. In other words, Newtonian dynamics must represent a special case of quantum dynamics appropriate to cases where the action is very large compared to the elementary quantum. This is indeed true; it should, however, be emphasized that quantum mechanics is really an extension of classical statistical mechanics rather than of the deterministic laws of Newton. As a result, one of the most important philosophical implications of quantum mechanics concerns the apparent breakdown of the causality principle in atomic phenomena. (*See* UNCERTAINTY PRINCIPLE, THE.)

The history of quantum mechanics may be divided into three main periods. The first of these began with Planck's theory of black body radiation in 1900, and may be described as the period in which the reality of Planck's constant of action was demonstrated, but its real meaning was rather obscure. The second period began with the Bohr theory in 1913. Niels Bohr's ideas gave the correct formula for the frequency of spectral lines in many cases, and were an enormous help in the codification and understanding of spectra. Still they did not represent a consistent, unified theory, as he himself recognized, but rather a sort of patchwork affair in which classical mechanics was subjected to a rather extraneous set of so-called "quantum conditions," which restrict the constants of integration to certain particular values. The true quantum mechanics appeared in 1926, reaching fruition almost simultaneously in a variety of forms, *viz.*, the matrix theory of Max Born and Werner Heisenberg, the wave mechanics of Louis V. de Broglie and Erwin Schrödinger, and the transformation theory of Paul A. M. Dirac and Pascual Jordan. These different formulations are in no sense alternative theories, but rather different aspects of a consistent body of law.

Since the laws of atomic physics were but imperfectly understood prior to 1926, previous editions of this encyclopaedia contained articles on "quantum theory" rather than "quantum mechanics." By 1946, however, the status could be aptly described by quoting a sentence or two, as follows (from Dirac in *Proceedings of the Royal Society* A, vol. 123): "The general theory of quantum mechanics is now almost complete, the imperfections that still remain being in connection with the exact fitting in of the theory with relativity ideas. These give rise to difficulties only when high-speed particles are involved, and are therefore of no importance in the consideration of atomic and molecular structure, and ordinary chemical reactions. . . . The underlying laws necessary for the mathematical theory of a large part of physics and the whole of chemistry are thus completely known, and the difficulty is only that the exact solution of these laws leads to equations much too complicated to be soluble." We ought perhaps to add that quantum mechanics made no pretense, as of 1946, of describing completely what goes on inside the nucleus. In other words, we do not know the details of the short-range dynamics of the neutrons, protons, etc., of which the nucleus is composed, although quantum mechanics has been a help in understanding many nuclear phenomena, such as the emission of alpha particles and photo-disintegration. In short, close to the mid-20th century the theory of nuclear physics was in a more or less embryonic stage comparable, say, with extra-nuclear quantum theory in its early days. Thus, quantum mechanics gave us the appropriate laws of nature down to distances of the order 10^{-10} cm., but we still did not know the rules in detail when we sought to probe below nuclear radii of the order 10^{-12} cm.

QUANTUM THEORY PRIOR TO THE BOHR ATOM

First, let us describe the earlier investigations in quantum theory which anteceded the discovery of the true quantum mechanics in 1926. This procedure is not merely an attempt to preserve historical order, but is also advisable because some of the primitive theories describe some subjects fairly well and help in the visualization of the later more recondite developments.

Black Body Radiation.—The quantum of action had its birth in the studies of black body radiation in 1900 by Planck, professor of physics at the University of Berlin. All black, *i.e.* perfectly absorbing, bodies heated to a given temperature should emit radiation having the same spectrum. The latter can be shown to be identical with the spectral distribution of energy in a so-called "hohlraum," *i.e.* a cavity whose radiation is in thermal equilibrium with matter. (*See* BLACK BODY.) According to classical physics, the density of radiant energy should be proportional to the square of the frequency, and so increase without limit as the wavelength is made progressively shorter. This prediction is sometimes called the "ultra-violet catastrophe," and the corresponding analytical formula for the energy density is called the Rayleigh-Jeans law. It yields the dashed curve of fig. 1. The observed distribution is that indicated by the solid curve, which Planck was able to deduce theoretically by making a quantum hypothesis.

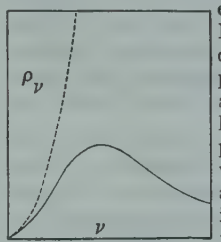

FIG. 1.—THE ENERGY DENSITY OF BLACK BODY RADIATION AS A FUNCTION OF FREQUENCY. CLASSICAL AND QUANTUM THEORIES GIVE RESPECTIVELY THE DASHED AND SOLID CURVES

We shall now indicate how the Rayleigh-Jeans and Planck radiation laws can be derived and shall formulate them mathematically. The method which we sketch is a well-known but rather formal one. It may be characterized as the application of classical equipartition or of classical statistics to the degrees of freedom of the ether. We do not mean to presume that a material ether really exists; we use this term merely to indicate that the standing electromagnetic waves in an enclosure are handled by the same type of statistical procedure as those of a material medium. The first step is the enumeration of the different types of standing waves or modes of vibration of the ether in a rectangular parallelopiped of volume V. Just as a rope with fixed ends can vibrate only in certain ways, represented by the fundamental and the various harmonics, so also in the three-dimensional case only certain modes of oscillation are compatible with the boundary conditions. If the edges of the parallelopiped are large compared to the wave length, the number of possible vibrations in the frequency interval ν, $\nu+d\nu$ can be shown to be

$$(8\pi\nu^2V/c^3)\cdot d\nu, \tag{1}$$

where c is the velocity of light. Let the mean energy of an oscillation of frequency ν be denoted by ϵ_ν. Then the density of radiant energy in the frequency range ν, $\nu+d\nu$ is $\rho_\nu d\nu$ with

$$\rho_\nu=\epsilon_\nu\cdot(8\pi\nu^2/c^3). \tag{2}$$

It is now necessary to evaluate ϵ_ν. This is done by treating each characteristic mode of vibration as a harmonic oscillator. According to classical statistical mechanics, we have

$$\epsilon_\nu=kT, \tag{3}$$

where k is Boltzmann's constant 1.38×10^{-16} erg/degree. Equation (3) is a direct consequence of the classical theory of equipartition. The latter demands that the mean kinetic energy per degree of freedom be $\frac{1}{2}kT$, and a harmonic oscillator has equal mean kinetic and potential energies, so that the total energy is kT. Substitution of (3) in (2) yields the Rayleigh-Jeans law

$$\rho_\nu=8\pi\nu^2kT/c^3. \tag{4}$$

The fact that ρ_ν increases without limit when ν is made arbitrarily large is the ultra-violet catastrophe already mentioned.

In quantum theory, however, the mean energy of a harmonic oscillator is taken to be

$$\epsilon_\nu=\frac{h\nu}{e^{h\nu/kT}-1}. \tag{5}$$

This formula is obtained by assuming that the energy of a harmonic oscillator is restricted to the "quantized" values 0, $h\nu$, $2h\nu$, $3h\nu$, $\cdots$. The mean energy is calculated by weighting these values in accordance with the usual Boltzmann factor, so that

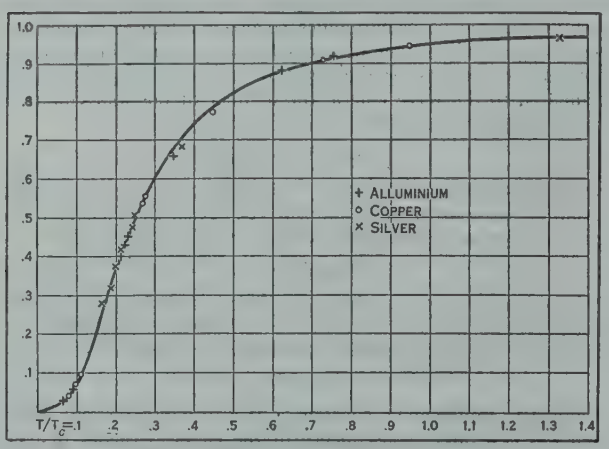
$$\epsilon_\nu=\frac{h\nu e^{-h\nu/kT}+2h\nu e^{-2h\nu/kT}+\cdots}{1+e^{-h\nu/kT}+e^{-2h\nu/kT}+\cdots} \tag{6}$$

The series in the numerator and denominator of (6) are readily summed, and the result is (5). Substitution of (5) in (2) gives

$$\rho_\nu = \frac{8\pi h\nu^3}{c^3} \cdot \frac{1}{e^{h\nu/kT}-1}. \qquad (7)$$

This is the celebrated Planck radiation formula. We have presented essentially one approach used by Planck. He also had other ways of obtaining his formula, but most of these have now been discarded. The best present derivation of the Planck radiation formula is probably one due to Albert Einstein in 1916, which is based on so-called detailed balancing for a system of matter and radiation.

Specific Heats.—Another early success of quantum theory was in the field of specific heats, where it explained the deviations from the law of Pierre L. Dulong and Alexis T. Petit. This law states that the specific heat per gram atom is very nearly the same, about six calories, for many solid elements. However, there are many exceptions. Also, if the temperature is lowered sufficiently, the specific heat approaches zero, instead of remaining constant, as predicted by the law. The behaviour of three metals, for instance, is shown in fig. 2. The law of Dulong and Petit is a direct consequence of the classical theory of equipartition, provided we apply the latter to the atom as a whole and arbitrarily do not attempt to apply classical statistics to the motion of the electrons inside the atom. The specific heat is then independent of temperature, and so in fig. 2 would be represented by a horizontal straight line of unit height in the scale employed there. Debye's quantum model, on the other hand, yields the solid curve, which is in good agreement with experiment. This curve approaches unity if the temperature is raised sufficiently. More generally, all classical and quantum theories of specific heats agree asymptotically at high temperatures. On the other hand, the vanishing of the specific heat at the absolute zero is a characteristic quantum phenomenon.



ADAPTED FROM T. PRESTON, "THEORY OF HEAT" (MACMILLAN)

FIG. 2.—THE SPECIFIC HEAT OF A MONATOMIC SOLID AS A FUNCTION OF TEMPERATURE. THE CURVE IS CALCULATED FROM DEBYE'S QUANTUM THEORY. THE SCALE OF ORDINATES IS SO CHOSEN THAT CLASSICAL THEORY GIVES UNITY

In the mathematical analysis the difference between the classical and quantum theories of the specific heats of solids parallels closely that between the proofs of the Rayleigh-Jeans and Planck laws for radiation. Instead of considering the electromagnetic vibrations of the ether, we have to deal with the vibrations of the atoms composing the solid with respect to each other. If the forces binding the atoms to their equilibrium positions obey Hooke's law, the vibrations are simple harmonic. The dynamical system represented by the aggregate of atoms constituting the solid obviously is exceedingly complicated, but, in principle, modes of vibration can be sorted out according to frequency. Let there be $n_\nu d\nu$ such modes in the interval ν, $\nu+d\nu$. Let the mean energy of a harmonic vibration be denoted by ϵ_ν, which, as before, has the value (3) or (5) according as we use classical or quantum theory. The total energy is obtained by integrating over all frequencies, and the specific heat c_V is the temperature derivative of the energy. Hence

$$c_V = \frac{d}{dT}\left[\int_0^\infty n_\nu \epsilon_\nu d\nu\right]. \qquad (8)$$

The determination of the factor n_ν specifying the distribution of vibration frequencies represents an exceedingly difficult problem, as n_ν is no longer given by the simple expression (1) which applied in the radiative case. However, if the classical result $\epsilon_\nu = kT$ is employed, it is not necessary to determine n_ν, as kT is merely a constant factor, which can be taken outside the integration. The integral can then be immediately evaluated from the relation

$$\int_0^\infty n_\nu d\nu = 3N, \qquad (9)$$

which states that the total number of independent modes of oscillation, or in other words the total number of degrees of freedom, must be three times the total number of atoms N. Hence, according to classical equipartition we have

$$c_V = 3Nk. \qquad (10)$$

This is essentially the law of Dulong and Petit. If we take an amount of material equal to a gram atom, so that N becomes the Avogadro number, and if we express the specific heat in calories rather than in ergs, then (10) gives a specific heat of 5.96 calories per degree.

In quantum theory, on the other hand, it is necessary to evaluate n_ν. Peter J. W. Debye assumed a distribution law for n_ν analogous to that (1) for the radiative case, but with allowance for transverse and longitudinal vibrations with different velocities of propagation, which can be calculated from the elastic constants of the material. There is then no limit to the high-frequency end of the spectrum, and the integrals in (8) and (9) diverge. To avoid this difficulty the upper limit in (8) and (9) is rather artificially taken to be ν_c rather than ∞, where ν_c is a "cut-off frequency" so chosen as to satisfy (9) and thus make the total number of vibrations equal to $3N$. With this model, Debye found $c_V = f(T/T_c)$, where $f(T/T_c)$ is a universal function of a "reduced temperature" T/T_c, which is the ratio of the ordinary temperature to a "characteristic temperature" T_c calculable from the elastic properties of the material. This reduced temperature is used for the abscissa in fig. 2. Debye's method for obtaining n_ν originally appeared somewhat artificial, but Born and Karmen showed that it had some dynamical basis. The Debye model applies only to simple monatomic solids. When the solid is composed of molecules, one must consider the vibrations not only of molecules with respect to each other, but also the vibrations of atoms inside the molecules. As emphasized by Einstein, the latter effect gives sharp maxima of n_ν at certain frequencies. In recent years, improved methods of calculating n_ν have been developed, and the theory correspondingly refined.

We have spoken so far only of solids. There is also considerable literature on the specific heats of gases. Here again, quantum theory explains deviations from the classical theory of equipartition, especially at low temperatures, which are particularly pronounced for hydrogen.

Photoelectricity.—Nowhere, perhaps, is the inadequacy of classical theory revealed more strikingly than in the subject of photoelectricity, which is concerned with emission of electrons by an illuminated body. (*See* PHOTOELECTRICITY.) Photoelectric phenomena exhibit two main features: (1) no emission occurs at all unless the frequency ν of the incident radiation exceeds a certain critical value, called the threshold frequency, and (2) the kinetic energy of the ejected electrons depends on the frequency of this radiation, and not on its intensity. In other words, if a light source is removed farther and farther from the body which it illuminates, the emitted electrons are undiminished in their velocity of escape, but are decreased in number. Such a state of affairs was a complete conundrum at the turn of the century, since in classical electromagnetic theory, diminished incident in-

tensity implies a lowering of the energy traversing the absorbing "target area," and as a result of the lower energy flow, the velocity imparted to the electron should be decreased, contrary to experiment. In 1905 Einstein showed that the observed behaviour could be explained if in the emission of the electron, a quantum of energy $h\nu$ is picked up by matter from the radiation, regardless of the latter's intensity. The process merely becomes less likely when the intensity is low. Just how such a corpuscular model was to be reconciled with the undulatory features of light, such as interference, was something not understood for two decades or so, but was finally clarified by the Heisenberg uncertainty principle, and by Bohr's theory of complementarity. From the less sophisticated outlook of 1905, Einstein showed that if we ignored the conflict with the wave viewpoint, his picture did indeed account for the salient factors of photoelectricity. The kinetic energy of escape of the electron will not in general be the same as the quantum $h\nu$ absorbed from the radiation inasmuch as part of the energy is consumed in liberating the electron from the metal. This portion is called the thermionic work function, and will be denoted by the letter ϕ. Einstein's equation for determining the velocity of escape v of an electron is thus

$$\tfrac{1}{2}mv^2 = h\nu - \phi. \qquad (11)$$

Since the kinetic energy $\frac{1}{2}mv^2$ is necessarily positive, emission is possible only if $\nu > \phi/h$. Hence ϕ/h is the threshold frequency.

Closely related to the photoelectric effect is the Compton effect (*q.v.*), which also reveals the need of the quantum hypothesis.

THE BOHR ATOM

A signal advance in quantum theory was achieved when a Danish physicist, Niels Bohr, propounded his theory of the spectrum of hydrogen, in 1913. By that time there was no doubt as to the validity of the Rutherford picture of the atom as a miniature solar system, with the nucleus and electrons playing respectively the role of the sun and the planets. (*See* ATOM.) The number of electrons in the neutral atom is the same as the chemists' atomic number, one for hydrogen, two for helium, etc. Therefore, the dynamics of the orbits of the electrons in the various atoms will be very complex except in the hydrogenic case, for the mathematical difficulties associated with even a three-body problem (*e.g.*, neutral helium, with one nucleus and two valence electrons) are enormous. By a hydrogenic atom we do not mean necessarily a hydrogen atom, but any other atom which has been stripped of all but one valence electron as a result of ionization. Examples are singly ionized helium, doubly ionized lithium, etc. Clearly, the study of the spectrum of hydrogen, because of its comparative simplicity, should be the most likely starting point of any attempt to decipher the complexities of atomic spectra.

The Balmer Formula.—It has long been known that there are some remarkable regularities in the spectrum of hydrogen. As early as 1885, Johann J. Balmer showed that the wave lengths λ of many lines are well represented by the empirical formula

$$\frac{1}{\lambda} = RZ^2\left[\frac{1}{n'^2} - \frac{1}{n''^2}\right], \qquad (12)$$

in which n', n'' are integers, and R is a constant, the so-called Rydberg one. If, for instance, one takes $n'=2$ and $n''=n'+1$, $n'+2$, $\cdots$, the expression (12) gives the wave lengths of the lines in what is called the Balmer series. The choices $n'=1$, 3, 4, and 5 yield respectively the Lyman, Paschen, Brackett and Pfund series, which were discovered later. Since the atomic number Z is unity for hydrogen, the factor Z^2 in (12) is unnecessary for present purposes, but is included to permit later extension to atoms of higher nuclear charge.

The Postulates of the Bohr Theory.—For many years, the *raison d'être* for the formula (12) was completely obscure. It is not surprising that the subject of line spectra was a closed book to the classical physicist. As some one has said, the task of constructing a model of the atom merely from knowledge of its spectra radiated under violent electrical or thermal excitation is comparable with trying to learn about a piano merely from the noise emitted when it is dropped downstairs. Bohr, however, showed that the behaviour (12) could be explained by means of two postulates, as follows:

(1) The existence of stationary states: In every atom there is a discrete succession of states, in any one of which the electrons can move without appreciable radiation, and which can be identified by a set of integers, usually called quantum numbers. The designation of these states as stationary refers to the absence of radiation from the orbits, in contravention of classical electrodynamics, and does not imply a static atom. Except for omission of the radiation corrections, the motion of the electrons in the stationary states is assumed to conform to the laws of classical mechanics.

(2) The Bohr frequency condition: It is assumed that an electron can sometimes pass discontinuously from one allowed orbit to another. In such a transition, the initial and final states will have different amounts of mechanical energy E″ and E′. To secure conservation of energy, the change in the mechanical energy must be counterbalanced by the absorption or emission of a light quantum, whose energy is $h\nu$ if the frequency is ν. This requirement yields the so-called Bohr frequency condition

$$h\nu = \mathrm{E}'' - \mathrm{E}'. \qquad (13)$$

The analogy to Einstein's photoelectric equation (11) is obvious.

In connection with the first postulate it is necessary to formulate the quantum conditions which restrict the energies of the atoms to certain particular values. The easiest case to handle is that of a simply periodic system, where the orbit repeats itself after a given interval of time τ. Here the quantization is effected by the relation

$$\overline{T} = \tfrac{1}{2}nh\nu_0, \qquad (14)$$

in which n is an integer, $\overline{T}$ is the mean kinetic energy of the system, *i.e.* the average of the kinetic energy T over a period, and $\nu_0 = 1/\tau$ is the frequency with which the orbit repeats itself. It is to be emphasized that the orbital frequency ν_0 is in general not the same as that ν given by the Bohr frequency condition (13). This nonidentity of the orbital and radiated frequencies is a celebrated paradox of the Bohr atom, as according to classical mechanics or actual observations on large-scale phenomena there is no distinction between the frequencies of motion of a system and those of the waves which it radiates. It should be mentioned, however, that in the Bohr theory there is an asymptotic agreement of the two frequencies for large quantum numbers, which is usually termed the "correspondence principle for frequencies."

Derivation of the Balmer Formula from the Bohr Theory.—We shall now show that the Balmer expression (12) is a consequence of the quantum condition (14) and the Bohr frequency condition. This derivation is such a simple and classic one that it seems worth giving, even though in a sense it is outmoded by more recent, but more intricate, calculations by means of wave mechanics, which also yield the result (12) with identically the same value of the Rydberg constant R as that obtained from the Bohr theory.

To simplify the calculations, we shall assume that the orbit is circular, but it can be shown that the energy levels are no different in the general case of ellipses. Let the mass of the nucleus and electron be denoted by M and m respectively, and let the nuclear and electronic charges be Ze and $-e$. Here e has the value 4.80×10^{-10} in electrostatic units, and Z is the atomic number. The centre of gravity, which may be supposed stationary, divides the line connecting the two particles in the inverse ratio of their masses. Hence, the electron and nucleus revolve around this centre in circles of radii $Ma/(m+M)$ and $ma/(m+M)$ respectively, where a is the distance from the nucleus to the electron. Since the angular velocity is $2\pi\nu_0$, the kinetic energy is

$$T = \tfrac{1}{2}\left[m\left(\frac{M}{m+M}\right)^2 + M\left(\frac{m}{m+M}\right)^2\right](2\pi\nu_0)^2a^2, \qquad (15)$$

This equation can also be written as

$$T=\tfrac{1}{2}\mu(2\pi\nu_0)^2a^2, \tag{16}$$

where μ is the so-called reduced mass, given by

$$\mu=mM/(m+M) \tag{17}$$

As T is constant in time, there is no distinction between T and $\overline{T}$. Thus application of the quantum condition (14) gives

$$(2\pi\nu_0)\mu a^2=nh/2\pi. \tag{18}$$

In other words, the angular momentum of the system is an integral multiple of $h/2\pi$. The equality between the centrifugal force on the electron and the Coulomb attraction due to the nucleus yields a further relation

$$\mu a(2\pi\nu_0)^2=Ze^2/a^2. \tag{19}$$

When equations (18) and (19) are solved for a and ν_0, the result is

$$a=n^2h^2/4\pi^2Ze^2\mu, \qquad \nu_0=4\pi^2\mu Z^2e^4/n^3h^3. \tag{20}$$

The first relation of (20) shows that the allowed or "quantized" values of the radius of the atom form a progression of the form $a_0, 4a_0, 9a_0, \cdots$, where a_0 is a fundamental unit $h^2/4\pi^2\mu Ze^2$ called the Bohr radius, and having the numerical value 0.53×10^{-8} cm. if Z=1 (hydrogen). Substitution of (20) in (16) gives

$$T=2\pi^2\mu Z^2e^4/n^2h^2,$$

while the potential energy is

$$V=-Ze^2/a=-4\pi^2\mu Z^2e^4/n^2h^2.$$

Hence the total energy E=T+V is

$$E=-2\pi^2\mu Z^2e^4/n^2h^2. \tag{21}$$

When we substitute this value of E in the Bohr frequency condition (13) and remember that $\lambda=c/\nu$, we have indeed the Balmer formula (12), provided the Rydberg constant R has the value

$$R=2\pi^2\mu e^4/ch^3. \tag{22}$$

One immediately asks whether (22) yields a value of R in agreement with the optical measurements, when the numerical values of the constants e, h, μ, c are substituted. The answer is that there is certainly agreement within the precision with which these constants are known, for e, h, μ are known only to one part in a thousand or so. On the other hand, since optical wave lengths are known so very accurately, the Rydberg constant R can be determined to within less than one part in a million. A valuable cross-check on the values of the various atomic constants is thus provided: namely, use of (22) along with the spectroscopic determination of R permits us to determine one of the four quantities e, h, μ, c if the other three are known. It is thus possible to increase the accuracy with which we know the value of the particular one of the four constants, viz. h, which otherwise cannot be as precisely determined as the other three.

Correction for the Motion of the Nucleus, and the Spectroscopic Determination of e/m.—If we neglect the motion of the nucleus, or in other words consider the mass M of the nucleus to be infinite, then equation (17) shows that the reduced mass becomes identical with the mass m of the electron. When allowance is made for the finite mass of the nucleus, μ will differ slightly from m. The neutral hydrogen atom and ionized helium atom resemble each other in having only one electron, so that formula (22) should be applicable to either. However, the different masses of the hydrogen and helium nuclei will make the Rydberg constant slightly different for the two. Just this state of affairs is found experimentally: the best spectroscopic value of the Rydberg constant for hydrogen is $R_H=109677.58$ cm.$^{-1}$, while that for helium is $R_{He}=109722.26$ cm.$^{-1}$ (Birge's figures). The corresponding value for a hydrogenic atom of infinite nuclear mass is $R\infty=109737.30$ cm.$^{-1}$.

Equation (22) shows that the ratio of the Rydberg constants for hydrogen and ionized helium is equal to the ratio of the reduced masses, the other constants cancelling out. When (17) is used, we can write

$$\frac{R_{He}}{R_H}=\frac{1+m/M_H}{1+m/xM_H}, \tag{23}$$

where x is the ratio M_{He}/M_H of the mass of the helium nucleus to that of hydrogen. This ratio can be regarded as known from determinations of atomic weights, since practically all of the atom's mass arises from the nucleus. Hence, by means of (23) and the spectroscopic determinations of R_H, R_{He}, it is possible to evaluate the ratio m/M_H of electronic to protonic mass. Furthermore, one can go a step farther and determine e/m spectroscopically, inasmuch as one has $e/m=(e/M_H)(M_H/m)$ and as the value of e/M_H is known from electrolysis, *i.e.* from the so-called electrochemical equivalent. In this way, the shift between the Rydberg constants for hydrogen and ionized helium furnishes perhaps the most accurate means of determining e/m. In the early 1930s there appeared to be a discrepancy between the values of e/m determined spectroscopically and by more direct deflection methods. This difficulty has now disappeared, and the generally accepted value of e/m is 1.759×10^7 e.m.u.

During the first years of Bohr's theory, the only known hydrogenic atoms, *i.e.* those with one valence electron, were H and He^+. Subsequently, X-ray measurements at Uppsala have revealed lines due to Li^{2+}, Be^{3+}, B^{4+} and C^{5+}. These lines are particularly useful because they furnish wave-length standards in the X-ray region. Another subsequent development was the discovery of the hydrogen isotope deuterium, which has about double the value of M for ordinary hydrogen and hence a slightly different Rydberg constant. This difference, in fact, historically furnished the means of initially demonstrating the existence of deuterium with certainty.

The Relativity Fine Structure.—A great triumph of the Bohr atom was the theory of the relativity fine structure in hydrogen, which was developed by Arnold Sommerfeld in 1916. In the preceding discussion, the problem was treated by means of Newtonian mechanics. When the relativity corrections are introduced, the orbits cease to be periodic, and the quantization becomes more complicated. It is necessary to introduce two quantum conditions, mathematical details of which we shall omit except for mentioning that they restrict the values of certain so-called "phase integrals" to integral multiples of Planck's constant. If the nuclear mass is treated as infinite, the formula for the energy can be shown to be

$$E=mc^2\left\{\left[1+\left(\frac{\alpha Z}{n-k+g}\right)^2\right]^{-\frac{1}{2}}-1\right\}, \tag{24}$$

where

$$\alpha=2\pi e^2/hc, \qquad g=(k^2-Z^2\alpha^2)^{\frac{1}{2}}, \tag{25}$$

If (24) be expanded as a power series in α^2, and terms beyond α^4 are disregarded, the expression for E takes the form

$$E=-\frac{2\pi^2mZ^2e^4}{n^2h^2}\left[1+\frac{\alpha^2Z^2}{n^2}\left(\frac{n}{k}-\frac{3}{4}\right)+\cdots\right]. \tag{26}$$

Since $m=\mu$ if $M=\infty$, the first term of (26) is the same as the Newtonian result (21), and involves only the principal quantum number n. The remainder of (26) is due to the relativity corrections, and involves a second quantum number k, which is the so-called azimuthal quantum number. Its physical significance is that the angular momentum is $kh/2\pi$, and the range of values for k is $1, 2, \cdots n$. The dependence of the energy on k is only a minor effect because of the smallness of α (=1/137.0), but it causes lines which would otherwise coincide to be slightly separated so as to form the components of a multiplet. A decomposition is indeed found experimentally, and on the whole the observed spacing of the components agrees well with theory.

The Stark Effect.—Still another quantitative success of the Bohr theory of the hydrogen spectrum is provided by the Stark effect, or splitting of the energy levels and hence of the spectral lines by means of an electric field. The separation and number of the components accords with theory in a remarkable fashion. The formulas for the displacement in frequency involve Planck's constant h, and so classical theory was powerless to explain any of the features of the Stark effect. On the other hand, in the

alternative phenomenon of the Zeeman effect (separation of lines in a magnetic field), Planck's h cancels out of the final formula for the shift in frequency, and so classical and quantum theories give identical results for the normal Zeeman effect (*q.v.*).

Moseley's Relation.—When one seeks to apply the Bohr concepts to nonhydrogenic atoms, the mathematical complexities are so great that the permitted energy levels or frequencies cannot be exactly determined. Nevertheless, certain successes of the theory should be stressed. One of these is the explanation of Moseley's relation in X-ray spectra, wherein the frequencies of the K lines, *i.e.* the hardest lines (lines of shortest wave length or highest frequency) are proportional approximately to the square of the atomic number. This is simply an expression of the factor Z^2 in (21). The result (21) applies approximately to an interior electron of a nonhydrogenic atom if the screening of the nucleus by the other electrons is so poor that the field is substantially that of the bare nucleus. This approximation will be a good one only for electrons which are deep-seated in the atom, such as are responsible for the emission of X-rays.

Relation between Critical Potentials and Spectral Frequencies.—By electron bombardment it is possible to "excite" an atom from one stationary state, say of energy E', to another of higher energy E''. To be able to do this, the impinging electron must have at least a kinetic energy equal to $E''-E'$, as otherwise conservation of energy cannot be secured. The energy which an electron acquires in falling through a difference of potential V is Ve. Hence, the minimum or "critical" accelerating potential required for the excitation is given by $Ve=E''-E'$. Alternatively, the Bohr frequency condition states that $h\nu=E''-E'$. Thus, we have $Ve=h\nu$, and this relation holds as a useful consequence of the theory, even though the mechanics of the many-body problem is so intricate that one cannot calculate theoretically the energy levels E', E''.

The Stern-Gerlach Effect.—The application of the quantum conditions to an atom in a magnetic field shows that its component of angular momentum in the direction of the field should be "quantized" and equal to an integral multiple of $h/2\pi$. The corresponding magnetic moment, which is proportional to the angular momentum, should hence likewise acquire only discrete values. Stern and Gerlach verified this prediction by observing the deflections of atoms in an inhomogeneous magnetic field. We cannot overemphasize how beautifully the existence of only certain particular deflections in their experiments demonstrates the reality of the quantized positions which are the essence of quantum theory. It is true that the explanation of the precise quantitative values of the deflections found by Stern and Gerlach requires inclusion of electron spin and the refinements of quantum mechanics in certain cases. However, the broad outlines of the phenomenon were clear even in the days of the Bohr theory, especially the complete contradiction between the classical continuous distribution of orientations and quantum discreteness. The Stern-Gerlach experiment decided unequivocably in favour of the latter.

The Harmonic Oscillator and the Rotator—Molecular Spectra.—There are two very simple schematic models which are particularly easy to quantize and which are rich in physical applications. They are the harmonic oscillator and the rigid rotator or "rotating dumbbell."

For a particle which is harmonically bound, *i.e.* subject to a linear restoring force, the mean kinetic energy is equal to the mean potential energy. Hence the total energy, which is the sum of the kinetic and potential, is equal to twice the mean kinetic energy. Furthermore, the frequency ν_0 of a harmonic oscillator is independent of the initial conditions. Therefore, application of (14) immediately yields the result

$$E=nh\nu_0. \tag{27}$$

The quantized values of the energy of a harmonic system given in (27) are the same as those which we previously used in discussing black-body radiation and specific heats.

For a rigid rotator, there is no potential energy, and the kinetic energy has the constant value $\frac{1}{2}I(2\pi\nu_0)^2$, where I is the moment of inertia, and ν_0 is the rotation frequency. The quantum condition (14) yields $2\pi\nu_0 I=nh/2\pi$. The quantization thus consists in equating the angular momentum to an integral multiple of $h/2\pi$. The corresponding quantized value of the energy is, since $E=T$,

$$E=n^2h^2/8\pi^2I. \tag{28}$$

These formulas have a direct application to the spectrum of a diatomic molecule such as HCl. As a first approximation, the energy of the molecule can be divided into contributions from (a) the electronic motion relative to the two nuclei regarded as fixed attracting centres, (b) the vibration of the two nuclei along the line connecting them, and (c) "end-over-end" rotation of the molecule as a whole. Effects (b) and (c) are respectively portrayed by the harmonic oscillator and the rotator. The quantum numbers associated with (b) and (c) are not, of course, the same, and so we use the letters v, J for them instead of n. The total energy of the molecule is thus

$$E=E_e+vh\nu_0+J^2h^2/8\pi^2I. \tag{29}$$

The electronic term E_e will be a function of numerous quantum numbers other than v, J, but is too difficult to compute explicitly because of the complexities of the many-body problem. The dependence on the rotational and vibrational quantum numbers v, J predicted by (29) agrees nicely with experiment (*see* BAND SPECTRUM).

Intensities and Transition Probabilities in the Bohr Theory.—The theory that we have so far presented is one-sided, as it tells us how to calculate the frequency, but nothing about the intensity. In order to have information about the latter, it is necessary to know the transition probability. It is a fundamental concept of the Bohr theory that radiation takes place sporadically and discontinuously, when an electron passes from one stationary state to another, rather than continuously as in classical theory. The transitions between states are governed by the statistics of random processes, like radioactive decay. Thus, if an electron is initially in a state l, there is a certain probability $A_{l\to m}$ that it will pass to another state m. Let us denote by $\nu(lm)$ the frequency associated with this transition, which by (13) is the same as $(E_l-E_m)/h$. Since an amount of energy $h\nu(lm)$ is radiated in each transition, the total rate at which energy is radiated in the frequency $\nu(lm)$ is

$$I_{l\to m}=h\nu(lm)A_{l\to m}N_l, \tag{30}$$

where N_l is the number of atoms in the state l.

Part of the contribution to $A_{l\to m}$ in the case of emission, and all in the case of absorption, will come from transitions induced by a radiation field. Even in the absence of the latter, however, there is a certain probability of "spontaneous radiation," provided the energy E_m of the final state is less than that E_l of the initial one. For simplicity, we shall consider only the spontaneous effect.

The problem is now to calculate the transition probability in the absence of a radiation field. Here the Bohr theory gave no clear-cut answer. The best that could be done was to make an approximate estimate by means of the so-called correspondence principle, which has been described as a "magic wand which enables one to borrow the results of classical theory for quantum theory." According to classical electrodynamics, an electron moving in a periodic orbit described by Fourier series such as

$$x=\sum_{\tau=-\infty}^{\infty} x_\tau e^{2\pi i\tau\nu_0 t}$$

radiates energy in the harmonic $\tau\nu_0$ at a rate

$$(4e^2/3c^3)(2\pi\tau\nu_0)^4[|x_\tau|^2+|y_\tau|^2+|z_\tau|^2].$$

The correspondence principle for frequencies shows that if the difference in quantum number between the initial and final states is τ, the quantum frequency $\nu(lm)$ approaches asymptotically the classical overtone $\tau\nu_0$ if the quantum number is large. Hence, a formula by which the transition probability can be estimated qualitatively or asymptotically is

$$A_{l\to m}=(4e^2/3hc^3)(2\pi)^4\nu(lm)^3[|x_{l-m}|^2+|y_{l-m}|^2+|z_{l-m}|^2]. \quad (31)$$

It is to be emphasized that (31) never gives a clear-cut and unambiguous answer, as there is no way of telling whether the Fourier coefficients should be evaluated for the initial or the final orbit of the transition, or should represent some sort of compromise between the two.

ADVENT OF THE TRUE QUANTUM MECHANICS

Although the Bohr theory had the many triumphs that we have indicated, still as time progressed, especially in the early 1920s, it became increasingly apparent that it was not adequate. With much labour one could determine the energy levels of the neutral helium atom, a three-body problem, and these did not accord with experiment. Unjustifiable half-quantum numbers, *i.e.* half rather than whole integers, kept appearing in the empirical description of band spectra. Numerous other difficulties could be recited. It was clear that the trouble was simply that the "old" or Bohr quantum theory was a patchwork doctoring of classical mechanics, wherein the quantum conditions were added in a rather artificial way. What was needed was a rational, self-consistent quantum mechanics, which started afresh and evolved a mathematical framework and philosophy all its own. This was discovered in 1926, which was thus an epoch-making year in the history of quantum theory.

This remarkable new mechanics cannot be regarded as the product of any one man, and was instead the result of the impact of mind on mind among the leading theoretical physicists of the time. It was developed in a diversity of mathematical forms, which present a rather confusing array to the student beginning the subject. However, these various formulations, though different in superficial mathematical structure, are basically in harmony with each other. The three main mathematical forms are the following: (1) the matrix theory of Born, Heisenberg and Jordan, (2) Schrödinger's wave mechanics, the outgrowth of De Broglie's concept of "phase waves" and (3) the so-called transformation theory, based on kinetical indeterminism, developed by Dirac and Jordan, and interpreted by Heisenberg.

WAVE MECHANICS
